PCF v2.2 Feature Highlights

This topic highlights important new features included in Pivotal Cloud Foundry (PCF) v2.2.

PCF Operations Manager (Ops Manager) Highlights

Ops Manager v2.2 includes the following major features:

Ops Manager API Documentation is Public

In time for the Ops Manager v2.2 release, Ops Manager API documentation is accessible publicly through docs.pivotal.io. Previously, you could only access the Ops Manager API documentation through your own Ops Manager.

For v2.2 Ops Manager API documentation, see [PCF Ops Manager API Reference](#).

Multiple Data Centers on vSphere

Ops Manager now supports multiple vSphere vCenters on a single vSphere BOSH Director tile. This allows you to spread instances across regions without having to deploy and manage multiple PCF foundations.

For more information about how to add, edit, and delete vCenters, see [Managing Multiple vSphere vCenters](#).

Selectively Deploy Tiles in Ops Manager or via an API Endpoint

You can now choose to deploy a selection of tiles rather than all tiles in Ops Manager. This feature allows you to reduce the amount of change in any given deployment, which drastically reduces deployment time.

This feature is in beta for Ops Manager, and is generally available as an API endpoint. For more information, see [Triggering an install process](#) in the Ops Manager API documentation.

Note: Ops Manager is soliciting feedback for this feature. Submit feedback through your product architect or directly by emailing opsmanager-feedback+selective_deploys@pivotal.io.

Ops Manager Stores Past Manifests

Through the Ops Manager API, you can see Ops Manager's manifest history. Manifest history is helpful for running `diff` commands on manifests to see changes over time.

Azure Stack is Generally Available

Pivotal officially supports Azure Stack.

Azure Stack is a hybrid cloud platform that lets you deliver Azure services from your own on-premise datacenter. For more information about Azure Stack, see [What is Azure Stack?](#) from the Microsoft Azure documentation.

Ops Manager Supports Azure China

Ops Manager now supports a special region in Azure called Azure China. Azure China is a physically separated instance of cloud services that is located in China and independently operated. For more information about Azure China, see [What is Azure China 21Vianet?](#) in the Azure China documentation.

Ops Manager Credentials Stored in CredHub

For even greater security, Ops Manager sends user-specified credentials to BOSH CredHub on each deployment. For more information about where Ops Manager-specific credentials are stored, see [BOSH CredHub](#).

For information about how this feature affects tile authors, see [PCF v2.2 Partners Release Notice](#) in the *PCF Tile Developer Guide*.

Secret Text Areas

Ops Manager v2.2 supports secret text areas in tile configuration panes. This feature is useful for tiles that require PCF operators to enter multi-line credentials during configuration.

When a user enters text into a secret text area and clicks **Save**, the Ops Manager UI replaces the text with an . Additionally, users of the Ops Manager API can not retrieve text entered in secret text areas. Ops Manager stores this text in CredHub.

Tile authors can mark a text area as `secret` by setting `type: secret` and `display_type: text_area` in the property blueprint for their tile.

For more information, see the [Custom Forms and Properties](#) section of the *Tile Generator* topic.

Specify a Custom Trusted SSL Certificate

Operators can specify a custom trusted SSL certificate and key for the Ops Manager server so that traffic isn't exposed to man-in-the-middle attacks when using Ops Manager.

By default, Ops Manager uses an auto-generated self-signed certificate. To change this configuration to your own SSL certificate, go to **Settings** from the Ops Manager Installation Dashboard and select the **SSL Certificate** pane. For more information about Ops Manager settings, see [Settings Page](#) in the *Understanding the Ops Manager Interface* topic.

 **Note:** Custom SSL certificate and key is persisted between upgrades. Custom SSL only needs a one-time configuration.

Configure an Ops Manager Syslog Server

You can configure a syslog server for Ops Manager logs. Logs include rails production logs, audit logs, UAA logs, nginx logs, and upstart logs for Ops Manager processes. Previous to this change, Ops Manager logs were not centralized in one accessible location. You also have the option to TLS-encrypt your logs.

For more information about configuring syslog for Ops Manager, see [Settings Page](#) in the *Understanding the Ops Manager Interface* topic.

TLS for Internal Blobstore Supported

Ops Manager now supports TLS communications for your internal blobstore. Ops Manager automatically generates and rotates TLS certifications for you.

To enable internal blobstore TLS communications, all of your tiles must have stemcells v3468 or later. You must also disable **Allow Legacy Agents** in the **Director Config** pane of the BOSH Director tile.

Custom TLS Certificate for External MySQL Database Supported

Ops Manager now allows you to configure a custom TLS certificate for an external MySQL database.

For more information, see the **Director Config Page** section of the [Ops Manager Director installation topic for your IaaS](#).

Custom Identification Tags Supported

If you have more than one PCF foundation, identification tags allow you to easily identify which foundation your VMs belong to when viewing your IaaS. You are able to set custom **Identification Tags** in the **Director Config** pane of your BOSH Director tile.

BOSH DNS Enabled By Default

BOSH DNS is enabled for both app containers and PCF components in v2.2. In previous versions, Consul managed service discovery between PCF components, but Consul is being replaced by BOSH DNS. BOSH DNS lets app containers and PCF components look up services with the BOSH DNS service discovery mechanism. To support BOSH DNS, the Ops Manager Director colocates a BOSH DNS server on every deployed VM. This does not negatively impact performance.

 **Note:** In PCF v2.2, Consul and BOSH DNS are both available in PCF, but BOSH DNS is the only service used for DNS requests.

BOSH DNS is enabled by default. You can disable BOSH DNS if instructed to do so by Pivotal support. From the Ops Manager installation dashboard, click the Ops Manager tile. In the **Director Config** tab, select the **Disable BOSH DNS server for troubleshooting purposes**.

 **warning:** Do not disable BOSH DNS without instructions from Pivotal support. Disabling BOSH DNS will also disable PKS, NSX-T, and several PAS features. If you disabled BOSH DNS in PCF v2.1, reenable it before upgrading to PCF v2.2.

Change Log Includes Products Deployed but Unchanged

The [Change Log](#) pane lists products as **Unchanged** when they remain deployed, but their configuration has not changed from a prior deployment, so Ops Manager did not re-deploy them.

Pivotal Application Service (PAS) Highlights

More Secure Cipher Suites for CF SSH

For greater security, the SSH proxy now accepts a narrower range of ciphers, MACs, and key exchanges when you call `cf ssh` from the CF CLI.

TLS-Encrypted Option for Internal System Databases

For internal system databases, PAS now supports a more secure [Percona Server](#) database with TLS-encrypted communication between server nodes, as well as the previous [MariaDB](#) option. See [Migrating to Internal Percona MySQL](#) for details.

 **warning:** Migrating PAS internal databases to using TLS causes temporary downtime of PAS system functions. It does not interrupt apps hosted by PAS.

Support for AWS Instance Profiles

PAS now supports [AWS instance profiles](#) when you are configuring an S3 filestore. Either an instance profile or an access and secret key are required.

For more information, see the **External or S3 Filestore** section of the [PAS installation topic for your IaaS](#).

Unversioned S3 Buckets for Backups

PAS can now back up unversioned S3 buckets used for external file storage, saving backup artifacts to separate, dedicated backup buckets. For more information, see the **External or S3 Filestore** section the [PAS installation topic for your IaaS](#).

Gorouter Logging Changes for GDPR Compliance

You can now disable logging of client IP addresses in the Gorouter to comply with the General Data Protection Regulation (GDPR).

For more information about this feature, see [Gorouter Logging Changes for GDPR Compliance](#) in *Pivotal Application Service v2.2 Release Notes*.

New Format for Diego Timestamps

You can now use a human- and machine-readable format, RFC 3339, for Diego timestamps in logs. RFC 3339 format also prevents the need for log aggregation systems to parse a complex timestamp.

New installations of the PAS, PAS for Windows, PAS for Windows 2012R2, and PCF Isolation Segment tiles now default to RFC 3339 format.

The Unix epoch format is set by default for upgrades to v2.2. You can enable the new timestamp format for Diego logs in the PAS tile.

For more information, see the **Configure Application Containers** section of the [PAS installation topic for your IaaS](#).

 **Breaking Change:** Before enabling RFC 3339 format for Diego logs, ensure that your log aggregation system anticipates the timestamp format change. If you experience issues, you can disable RFC 3339 format in the PAS tile.

Service Discovery for Container-to-Container Networking Enabled By Default

In PAS v2.1, service discovery for container-to-container networking was an experimental feature that you could opt in to use. In PAS v2.2, this feature is enabled by default, and you can opt out of using it.

For more information about disabling service discovery for container-to-container networking, see the **Configure Application Developer Controls** section of the [PAS installation topic for your IaaS](#).

DNS Search Domains

PAS v2.2 allows you to configure the DNS search domains used in containers by entering a comma-separated list.

For more information, see the **Container Networking** section of the [PAS installation topic for your IaaS](#).

Loggregator Introduces Log Cache

Loggregator adds an in-memory caching layer for logs and metrics and provides a RESTful interface for retrieving them. Unlike the `cf logs APP-NAME --recent` command, Log Cache gives you queryable, filterable data when you use it to retrieve recent logs for your apps.

For more information, see [Enable Log Cache](#).

 **Breaking Change:** If you disable Log Cache, App Autoscaler will fail. For more information about Log Cache, see [Loggregator Introduces Log Cache](#).

Forwarding of DEBUG Syslog Messages Disabled by Default

PAS v2.2 adds the **Don't Forward Debug Logs** checkbox, which disables forwarding of DEBUG syslog messages to external services.

The **Don't Forward Debug Logs** checkbox is enabled in PAS v2.2 by default. For more information about this feature, see [Forwarding of DEBUG Syslog Messages Disabled by Default](#)

Improved App Autoscaler CLI

App Autoscaler now allows you to create custom autoscaling rules and scheduled limit changes for your apps through the App Autoscaler CLI.

For more information about the App Autoscaler CLI, see [Using the App Autoscaler CLI](#).

Apps Manager Highlights

App Autoscaler UI Integrated into Apps Manager

The App Autoscaler UI is now integrated into Apps Manager. This enables users to configure autoscaling for their apps through Apps Manager.

For more information about scaling apps using App Autoscaler, see [Scaling an Application Using App Autoscaler](#).

PCF Isolation Segment Highlights

Gorouter Logging Changes for GDPR Compliance

See [Pivotal Application Service \(PAS\) Highlights](#) above and [Gorouter Logging Changes for GDPR Compliance](#) in *PCF Isolation Segment v2.2 Release Notes*.

New Format for Diego Timestamps

PCF Isolation Segment shares the [New Format for Diego Timestamps](#) feature in PAS.

DNS Search Domains

PCF Isolation Segment shares the new [DNS Search Domains](#) feature in PAS.

Pivotal Cloud Foundry Release Notes

Pivotal Cloud Foundry is certified by the Cloud Foundry Foundation for 2019.

Read more about the [certified provider program](#) and the [requirements of providers](#).

This topic provides links to the release notes for Pivotal Cloud Foundry (PCF). Release notes include new features, breaking changes, bug fixes, and known issues.

To find release notes for PCF services, navigate to the documentation for the desired service from [Pivotal Documentation](#).

Stemcell Release Notes

[Stemcell Release Notes](#)

PCF v2.2 Breaking Changes

This topic describes the breaking changes you need to be aware of when upgrading to Pivotal Cloud Foundry (PCF) v2.2. For more information about important preparation steps you must follow before beginning an upgrade, see [Upgrading Pivotal Cloud Foundry](#).

Pivotal Cloud Foundry

[PKS v1.3 Does Not Support Ops Manager v2.2](#)

PKS v1.3 only supports Ops Manager v2.3 and v2.4. Do not use PKS v1.3 with any other version of Ops Manager.

Tile Patch Releases Use Xenial Stemcells

Ubuntu 14.04 LTS (Trusty) stemcells are reaching end-of-support in April 2019. Starting in September 2018, Pivotal and its partners will begin releasing product tile versions for PCF that require Ubuntu 16.04 LTS (Xenial) stemcells instead of Trusty stemcells. Using Xenial stemcells is necessary to avoid exposure to security vulnerabilities. A PCF deployment may include some products running on Trusty stemcells and others running on Xenial.

Before deploying any tiles that require a Xenial stemcell, you must manually download and import a new Xenial stemcell into the **Ops Manager Stemcell Library**. As a consequence of using Xenial stemcells, any automation you have set up to update the existing tile using Trusty stemcells may break.

Before you upgrade PCF, always verify that any tiles that you have installed, either from Pivotal or a partner, are compatible with the version of PCF you are deploying and its supported stemcells. For more information on checking PCF and stemcell compatibility, see [Tile Compatibility](#) in the Upgrade Checklist.

To find out which stemcell version is used by a product tile version, check the release notes or the Pivotal Network download page for the tile.

Pivotal Application Service (PAS)

Downtime when Upgrading from v2.1 to v2.2.7 or Later

Upgrading directly from PAS v2.1.x to v2.2.7 or later may cause significant app downtime. If you are upgrading from v2.1.x, Pivotal recommends that you upgrade to v2.2.6 or an earlier patch release of v2.2.x. Once you are on v2.2.6 or an earlier patch release of v2.2.x, you can then upgrade to v2.2.7.

A fix for this issue is planned for v2.2.12.

For more information, see the following article in the Pivotal Knowledge Base: [How to avoid app downtime while upgrading from PAS v2.1.x to v2.2.7](#).

CredHub Database Cannot be External on GCP

Log Aggregation Systems May Parse Diego Timestamps Incorrectly

The timestamps in the Diego component logs are now in a format compatible with [RFC 3339](#).

This timestamp format is enabled by default for new PAS v2.2 deployments. Upgrades from earlier PAS versions retain the previous component log format with Unix epoch timestamps.

You can enable the new timestamp format in your PAS tile configuration. Before enabling the new timestamp format for Diego logs, ensure that your log aggregation system anticipates the timestamp format change.

If you experience issues, you can disable RFC 3339 format in the PAS tile. For more information about this PCF v2.2 feature, see [PCF v2.2 Feature Highlights](#) and [New Format for Timestamps in Diego Component Logs](#) in *Pivotal Application Service v2.2 Release Notes*.

SSH Proxy May Restrict Client Access

The SSH proxy now accepts a narrower range of ciphers, MACs, and key exchanges. This feature may have complications if you use a SSH client other than `cf ssh` to connect. For more information, see [Application SSH Access without cf CLI](#).

Temporary Downtime when Migrating Internal System Databases

If you use internal system databases, migrating the databases to the new option of **Internal Databases - MySQL - Percona XtraDB Cluster** causes temporary downtime of PAS system functions. Migrating the database does not interrupt apps running on PAS, but does temporarily prevent you from pushing new ones. For more information, see [Migrating to Internal Percona MySQL](#).

PAS v2.2 deprecates the MariaDB Galera internal database option, and Pivotal plans to remove MariaDB Galera as a database option in PAS v2.3. To continue using internal system databases in future versions of PAS, you need to migrate them to Percona while you are running PAS v2.2, or else when you upgrade to PAS v2.3.

This change has no effect if you have **External Databases** selected in the PAS tile **Databases** pane.

App Autoscaler Fails When Loggregator's Log Cache Is Disabled

App Autoscaler relies on API endpoints in Loggregator's Log Cache component. If you disable Log Cache, App Autoscaler will fail. For more information about Log Cache, see [Loggregator Introduces Log Cache](#).

Read-only Volume Mounts

We back-ported a fix from NFS 1.3.1 to NFS 1.2.1 for an incompatibility between our NFS Volume release and Diego's container runtime, garden. But, because the fix was in the NFS Service Broker, and service bindings created by old versions of this broker won't get migrated during upgrade, existing NFS service bindings that specify read-only mounts will still exhibit the incompatibility.

As a result, customers upgrading from versions containing `nfs-volume-release < 1.2.1` that have NFS services bound read-only to their applications will see that their applications crash after upgrade.

To fix this condition, customers should unbind the service, rebind it, and then restage the application.

Alternately, customers wishing to avoid application down time can temporarily re-bind their applications as read/write before upgrading, and then switch to read-only afterwards.

Diego Cell Garden Healthcheck Fails and Becomes Unhealthy

You may observe the following error in the Diego Cell Garden logs:

```
cfnetworking: cni up failed: add network list failed: initialize net out: creating chain: iptables call: running [/var/vcap/packages/iptables/sbin/iptables -t filter -N netout--executor-healthcheck --wait]: exit status 1: ip
```

This is a symptom of a failed Diego healthcheck, which can cause the Diego cell to become unhealthy. If you encounter this error, see the following Pivotal Knowledge Base article to understand and resolve the issue: [Diego Cell Garden healthcheck fails and becomes unhealthy](#).

PCF Operations Manager (Ops Manager)

Redeploy All Products After Upgrading to Ops Manager v2.2

When upgrading to PCF v2.2, redeploy all product tiles by clicking **Apply Changes** in the Ops Manager installation dashboard. A universal redeploy ensures that the updated BOSH DNS release applies consistently to all products.

Do not use the **Review Pending Changes** button to deploy product tiles individually during the upgrade to PCF v2.2. Instead, redeploy everything and selectively deploy individual product tiles only after you have successfully upgraded to PCF v2.2.

For more information about selective deployment, see [\(Beta\) Selectively Deploy Ops Manager Tiles](#).

Ops Manager Logs Have Changed Locations

Ops Manager centralized its logs in `/var/log/opsmanager` so that you can now configure a syslog server in the Ops Manager **Settings**.

Because of this change for Ops Manager v2.2, you cannot run scripts to fetch Ops Manager logs at their previous locations. For example, you cannot fetch logs from `/var/tempest` or `/var/vcap/sys`.

For more information about the syslog feature, see [Configure an Ops Manager Syslog Server](#) in the *PCF Ops Manager v2.2 Release Notes*.

Ops Manager API Does Not Return Secret Properties

For security, Ops Manager API responses from the `/api/v0/staged/director/properties` endpoint no longer include the following properties:

- GCS blobstore service key `service_account_key` (on Google Cloud Services)
- Health Monitor emailer SMTP password `smtp_password`
- Health Monitor PagerDuty service key `service_key`

This change may break any code that relies on retrieving these properties from a `GET /api/v0/staged/director/properties` call.

For more information, see the [Ops Manager API v2.2 documentation](#).

PCF Isolation Segment

Log Aggregation Systems May Parse Diego Timestamps Incorrectly

See [New Format for Timestamps in Diego Component Logs](#) in *PCF Isolation Segment v2.2 Release Notes* and breaking changes for [Pivotal Application Service \(PAS\)](#) for more information.

PCF Ops Manager v2.2 Release Notes

Pivotal Cloud Foundry is certified by the Cloud Foundry Foundation for 2019.

Read more about the [certified provider program](#) and the [requirements of providers](#).

Note: Ops Manager API documentation is now public. For more information, see [PCF v2.2 Feature Highlights](#).

How to Upgrade

The [Upgrading Pivotal Cloud Foundry](#) topic contains instructions for upgrading to Pivotal Cloud Foundry (PCF) Ops Manager v2.2.

Releases

2.2.24

Ops Manager v2.2.24 uses the following component versions:

| Component | Version |
|----------------|----------------|
| Ops Manager | 2.2-build.468* |
| Stemcell | 3586.118 |
| BBR SDK | 1.6.0 |
| BOSH Director | 266.16.0 |
| BOSH DNS | 1.10.0 |
| Metrics Server | 0.0.22 |
| CredHub | 1.9.12 |
| Syslog | 11.4.0 |
| UAA | 57.10* |
| BPM | 0.12.3 |
| Networking | 8 |
| OS Conf | 20.0.0 |
| AWS CPI | 70 |
| Azure CPI | 35.5.2* |
| Google CPI | 27.0.1 |
| OpenStack CPI | 38 |
| vSphere CPI | 50.0.4 |
| Credhub CLI | 1.7.7 |
| BBR CLI | 1.5.1 |

** Components marked with an asterisk have been updated.*

2.2.23

- **[Bug Fix]** UAA session timeouts obey the access or refresh token lifetime.

Ops Manager v2.2.23 uses the following component versions:

| Component | Version |
|-------------|----------------|
| Ops Manager | 2.2-build.464* |
| Stemcell | 3586.118* |

| Component | Version |
|---|----------|
| BBR SDK | 1.6.0 |
| BOSH Director | 266.16.0 |
| BOSH DNS | 1.10.0 |
| Metrics Server | 0.0.22 |
| CredHub | 1.9.12 |
| Syslog | 11.4.0 |
| UAA | 57.9 |
| BPM | 0.12.3 |
| Networking | 8 |
| OS Conf | 20.0.0 |
| AWS CPI | 70 |
| Azure CPI | 35.4.0 |
| Google CPI | 27.0.1 |
| OpenStack CPI | 38 |
| vSphere CPI | 50.0.4 |
| Credhub CLI | 1.7.7 |
| BBR CLI | 1.5.1* |
| * Components marked with an asterisk have been updated. | |

2.2.22

- **[Bug Fix]: Apply Changes** no longer fails if copying credentials to CredHub takes longer than ten minutes.
- **[Bug Fix]:** Exporting installation settings no longer causes the BOSH Director to incorrectly show that it has staged changes.
- **[Bug Fix]:** Harbor now installs successfully on deployments that already have PKS installed. For more information about Harbor, see [VMware Harbor Registry](#).
- **[Bug Fix]:** Operators can no longer change persistent disk size to custom values.

Ops Manager v2.2.22 uses the following component versions:

| Component | Version |
|----------------|----------------|
| Ops Manager | 2.2-build.457* |
| Stemcell | 3586.100* |
| BBR SDK | 1.6.0 |
| BOSH Director | 266.16.0 |
| BOSH DNS | 1.10.0 |
| Metrics Server | 0.0.22 |
| CredHub | 1.9.12* |
| Syslog | 11.4.0 |
| UAA | 57.9 |
| BPM | 0.12.3 |
| Networking | 8 |
| OS Conf | 20.0.0 |
| AWS CPI | 70 |
| Azure CPI | 35.4.0 |
| Google CPI | 27.0.1 |
| OpenStack CPI | 38 |
| vSphere CPI | 50.0.4 |
| Credhub CLI | 1.7.7 |
| BBR CLI | 1.5.1* |

| BBR CLI Component | 1.5.0 Version |
|---|------------------|
| * Components marked with an asterisk have been updated. | |

2.2.21

- **[Bug Fix]:** You can now configure Azure deployments to use Availability Zones after upgrading from an earlier version.
- **[UI Improvement]:** The notification banner that appears when a certificate in your deployment is about to expire is updated for clarity.

Ops Manager v2.2.21 uses the following component versions:

| Component | Version |
|---|----------------|
| Ops Manager | 2.2-build.436* |
| Stemcell | 3586.93* |
| BBR SDK | 1.6.0 |
| BOSH Director | 266.16.0 |
| BOSH DNS | 1.10.0 |
| Metrics Server | 0.0.22 |
| CredHub | 1.9.11* |
| Syslog | 11.4.0 |
| UAA | 57.9 |
| BPM | 0.12.3 |
| Networking | 8 |
| OS Conf | 20.0.0 |
| AWS CPI | 70 |
| Azure CPI | 35.4.0 |
| Google CPI | 27.0.1 |
| OpenStack CPI | 38 |
| vSphere CPI | 50.0.4 |
| Credhub CLI | 1.7.7 |
| BBR CLI | 1.5.0* |
| * Components marked with an asterisk have been updated. | |

2.2.20

- There are no additional features or fixes in this release.

Ops Manager v2.2.20 uses the following component versions:

| Component | Version |
|----------------|---------------|
| Ops Manager | 2.2-build.427 |
| Stemcell | 3586.86 |
| BBR SDK | 1.6.0 |
| BOSH Director | 266.16.0 |
| BOSH DNS | 1.10.0 |
| Metrics Server | 0.0.22 |
| CredHub | 1.9.9 |
| Syslog | 11.4.0 |
| UAA | 57.9 |
| BPM | 0.12.3 |
| Networking | 8 |
| OS Conf | 20.0.0 |

| Component | Version |
|--|------------------|
| AWS CPI | 70 |
| Azure CPI | 35.4.0 |
| Google CPI | 27.0.1 |
| OpenStack CPI | 38 |
| vSphere CPI | 50.0.4 |
| Credhub CLI | 1.7.7 |
| BBR CLI | 1.4.0 |
| <i>Components marked with an asterisk have been updated.</i> | |

2.2.19

- **[Security Fix]:** Updates bootstrap from 3.4.0 to 3.4.1.

Ops Manager v2.2.19 uses the following component versions:

| Component | Version |
|--|----------------|
| Ops Manager | 2.2-build.424* |
| Stemcell | 3586.79 |
| BBR SDK | 1.6.0 |
| BOSH Director | 266.16.0 |
| BOSH DNS | 1.10.0 |
| Metrics Server | 0.0.22 |
| CredHub | 1.9.9 |
| Syslog | 11.4.0 |
| UAA | 57.7 |
| BPM | 0.12.3 |
| Networking | 8 |
| OS Conf | 20.0.0 |
| AWS CPI | 70 |
| Azure CPI | 35.4.0 |
| Google CPI | 27.0.1 |
| OpenStack CPI | 38 |
| vSphere CPI | 50.0.4 |
| Credhub CLI | 1.7.7 |
| BBR CLI | 1.4.0* |
| <i>* Components marked with an asterisk are updated.</i> | |

2.2.18

- There are no additional features or fixes in this release.

Ops Manager v2.2.18 uses the following component versions:

| Component | Version |
|----------------|----------------|
| Ops Manager | 2.2-build.418* |
| Stemcell | 3586.79* |
| BBR SDK | 1.6.0 |
| BOSH Director | 266.16* |
| BOSH DNS | 1.10.0 |
| Metrics Server | 0.0.22 |

| Component | Version |
|--|---------|
| Syslog | 11.4 |
| UAA | 57.7 |
| AWS CPI | 70 |
| Azure CPI | 35.4 |
| GCP CPI | 27.0.1 |
| OpenStack CPI | 38 |
| vSphere CPI | 50.0.4 |
| <i>* Components marked with an asterisk are updated.</i> | |

2.2.17

- **[New Feature]:** You can now upgrade from the most recent version of v2.2, which may use multiple NATS certificate authorities (CAs) to a version of v2.3 that only supports one NATS CA and was released prior to the version of v2.2 from which you are upgrading.
- **[New Feature]:** You can now change a selected option of a selector through the API using the human-readable name of the option. Send a `PUT` to `/api/v0/staged/products/:guid/properties` with a `selected_option` key. The `PUT` API endpoint can also parse both `value`, for the human-readable value, and `option_value`, for the machine-readable value.
- **[Bug Fix]:** When an Azure-based Ops Manager Director is configured with invalid Azure account credentials (such as a subscription ID, tenant, or other credentials) and you try to create a network, you now an error message, rather than a 500 error.
- **[Bug Fix]:** Ops Manager now uses GCP images that are located in the United States. This should prevent image object generation problems sometimes seen in images based in Europe and Asia.
- **[Bug Fix]:** The Azure CPI is reverted to 35.4 to resolve a customer issue.

Ops Manager v2.2.17 uses the following component versions:

| Component | Version |
|--|----------------|
| Ops Manager | 2.2-build.414* |
| Stemcell | 3586.70 |
| BBR SDK | 1.6.0 |
| BOSH Director | 266.15 |
| BOSH DNS | 1.10.0 |
| Metrics Server | 0.0.22 |
| CredHub | 1.9.3 |
| Syslog | 11.4 |
| UAA | 57.7 |
| AWS CPI | 70 |
| Azure CPI | 35.4* |
| GCP CPI | 27.0.1 |
| OpenStack CPI | 38 |
| vSphere CPI | 50.0.4 |
| <i>* Components marked with an asterisk are updated.</i> | |

2.2.16

- **[Security Fix]:** A potential XSS vulnerability in the `resource_config` API endpoint is mitigated.
- **[New Feature]:** NATS certificate information, including expiration dates, is now available through the API. Use the `api/v0/deployed/certificates` endpoint to view this information.
- **[New Feature]:** You can now use the BOSH Backup and Restore (BBR) CLI from the Ops Manager VM. This means you no longer have to download or upgrade BBR when you upgrade the Ops Manager VM.
- **[Bug Fix]:** Ops Manager now reloads NGINX when the configuration is updated. Previously, Ops Manager would restart NGINX, which could cause temporary downtime. NGINX now serves traffic consistently when it is updating.

Ops Manager v2.2.16 uses the following component versions:

| Component | Version |
|---|----------------|
| Ops Manager | 2.2-build.406* |
| Stemcell | 3586.70* |
| BBR SDK | 1.6.0 |
| BOSH Director | 266.15* |
| BOSH DNS | 1.10.0 |
| Metrics Server | 0.0.22* |
| CredHub | 1.9.3 |
| Syslog | 11.4* |
| UAA | 57.7* |
| AWS CPI | 70 |
| Azure CPI | 35.5 |
| GCP CPI | 27.0.1 |
| OpenStack CPI | 38 |
| vSphere CPI | 50.0.4 |
| * Components marked with an asterisk are updated. | |

2.2.15

- **[Security Fix]:** Information about the web server (NGINX) no longer appears in server response headers.
- **[New Feature]:** Credentials now return in some API calls. If you have sufficient permissions, sending a GET to `director/properties` or `director/iaas_configurations/guid` or `products/guid/properties` with the `redact=false` parameter will return all keys and values, including credentials.
- **[Feature Improvement]:** Selectors without a default option display in the list of `/api/v0/staged/products/product-guid/properties` as `null`.
- **[Feature Improvement]:** Some error messages that appear in the API are more reader-friendly.
- **[Bug Fix]:** You can no longer export using the API without deploying.
- **[Bug Fix]:** `/api/v0/deployed/director/manifest` now works when upgrading from 2.1 to 2.2.
- **[Bug Fix]:** Installation Change records now have a deployment status other than `null`.

Ops Manager v2.2.15 uses the following component versions:

| Component | Version |
|---|----------------|
| Ops Manager | 2.2-build.398* |
| Stemcell | 3586.66* |
| BBR SDK | 1.6 |
| BOSH Director | 266.14 |
| BOSH DNS | 1.10.0 |
| Metrics Server | 0.0.21 |
| CredHub | 1.9.3 |
| Syslog | 11.3 |
| UAA | 57.6 |
| AWS CPI | 70 |
| Azure CPI | 35.5 |
| GCP CPI | 27.0.1 |
| OpenStack CPI | 38 |
| vSphere CPI | 50.0.4 |
| * Components marked with an asterisk are updated. | |

2.2.14

- **[Bug Fix]:** Viewing product properties API endpoint for selector properties no longer fails when no option is selected, it returns null for that field.
- **[Security Fix]:** GETs to any Ops Manager or UAA API endpoint no longer return any information about the web server, including version numbers.

Ops Manager v2.2.14 uses the following component versions:

| Component | Version |
|---|----------------|
| Ops Manager | 2.2-build.386* |
| Stemcell | 3586.60 |
| BBR SDK | 1.6 |
| BOSH Director | 266.14 |
| BOSH DNS | 1.10.0 |
| Metrics Server | 0.0.21 |
| CredHub | 1.9.3 |
| Syslog | 11.3 |
| UAA | 57.6 |
| AWS CPI | 70 |
| Azure CPI | 35.5* |
| GCP CPI | 27.0.1 |
| OpenStack CPI | 38 |
| vSphere CPI | 50.0.4 |
| * Components marked with an asterisk are updated. | |

2.2.13

- **[New Feature]:** A banner appears on the Dashboard when certificates are about to expire.
- **[New Feature]:** The Ops Manager API has a selected option identifier for a selector property. For example, `properties.SELECTOR_NAME.SELECTOR_OPTION.OPTION-NAME`. This helps identify what properties are associated with the selected option on a selector.
- **[New Feature]:** Ops Manager operators with permissions to see credentials can send a `GET` to `director/properties`, `director/iaas_configurations/guid`, `director/iaas_configurations`, or `products/guid/properties` with the `redact=false` parameter to see an API response that includes credentials.
- **[Bug Fix]:** The API docs corrected `PUT /api/v0/settings/ssl_certificate` details.

Ops Manager v2.2.13 uses the following component versions:

| Component | Version |
|----------------|----------------|
| Ops Manager | 2.2-build.382* |
| Stemcell | 3586.60* |
| BBR SDK | 1.6 |
| BOSH Director | 266.14 |
| BOSH DNS | 1.10.0 |
| Metrics Server | 0.0.21 |
| CredHub | 1.9.3 |
| Syslog | 11.3 |
| UAA | 57.6 |
| AWS CPI | 70 |
| Azure CPI | 35.4 |
| GCP CPI | 27.0.1 |
| OpenStack CPI | 38 |
| | |

| Component | Version |
|---|---------|
| * Components marked with an asterisk are updated. | |

2.2.12

- **[Security Fix]:** Bumps activejob to 5.0.4 to resolve [CVE-2018-16476](#).
- **[New Feature]:** Ops Manager operators with sufficient permissions to see credentials can now send a GET to `director/properties`, `director/iaas_configurations/guid`, `director/iaas_configurations`, or `products/guid/properties` with the `redact=false` parameter to see an API response that includes credentials.
- **[Feature Improvement]:** When a user who has not logged into Ops Manager is prompted to log in to view a page, logging in returns them to the page they tried to access, rather than the Installation Dashboard.
- **[Bug Fix]:** Internal IDP metadata no longer changes when authentication protocols switch between internal authentication and SAML. Specifically, the `ds:DigestValue` and `ds:SignatureValue` values no longer change.
- **[Bug Fix]:** The API docs now show `instance_groups` in some locations where they previously referenced jobs.

Ops Manager v2.2.12 uses the following component versions:

| Component | Version |
|---|----------------|
| Ops Manager | 2.2-build.379* |
| Stemcell | 3586.57 |
| BBR SDK | 1.6 |
| BOSH Director | 266.14 |
| BOSH DNS | 1.10.0 |
| Metrics Server | 0.0.21 |
| CredHub | 1.9.3 |

| OpenStack CPI | 38 |
| vSphere CPI | 50.0.3* |
| * Components marked with an asterisk are updated. | |

2.2.11

- **[Bug Fix]:** The SAML certificate now regenerates when authentication method changes from SAML to internal, rather than when SAML is enabled. This facilitates a greater number of authentication method workflows, including those which change Ops Manager metadata.
- **[Bug Fix]:** Ops Manager now captures changes to the database, including reversions to old passwords, more completely.
- **[Feature Improvement]:** There are now API docs for the GET and PUT `ssh_banner_contents` endpoints.

Ops Manager v2.2.11 uses the following component versions:

| Component | Version |
|----------------|----------------|
| Ops Manager | 2.2-build.376* |
| Stemcell | 3586.57 |
| BBR SDK | 1.6 |
| BOSH Director | 266.14 |
| BOSH DNS | 1.10.0 |
| Metrics Server | 0.0.21 |
| CredHub | 1.9.3 |
| Syslog | 11.3 |

| Component | Version |
|--|---------|
| AWS CPI | 70 |
| Azure CPI | 35.4 |
| GCP CPI | 27.0.1 |
| OpenStack CPI | 38 |
| vSphere CPI | 50 |
| <i>* Components marked with an asterisk are updated.</i> | |

2.2.10

- **[Security Fix]:** Upgrades Loofah to 2.2.3 to address a CVE.
- **[Security Fix]:** Upgrades Rack to 2.0.6 to address a CVE.
- **[New Feature]:** A Pivotal-specific GUID now appears in the global CPI options for Azure deployments. View this key/value pair in the CPI configuration of the BOSH Director manifest.

Ops Manager v2.2.10 uses the following component versions:

| Component | Version |
|--|----------------|
| Ops Manager | 2.2-build.372* |
| Stemcell | 3586.57* |
| BBR SDK | 1.6 |
| BOSH Director | 266.14* |
| BOSH DNS | 1.10.0 |
| Metrics Server | 0.0.21 |
| CredHub | 1.9.3 |
| Syslog | 11.3 |
| UAA | 57.6 |
| AWS CPI | 70 |
| Azure CPI | 35.4 |
| GCP CPI | 27.0.1 |
| OpenStack CPI | 38 |
| vSphere CPI | 50 |
| <i>* Components marked with an asterisk are updated.</i> | |

2.2.9

- **[Security Fix]:** Bumps Nokogiri to 1.8.5 to address [CVE-2018-14404](#).
- **[Security Fix]:** Bumps UAA to 57.6 to address [CVE-2018-15761](#).
- **[Bug Fix]:** Now Application Load Balancers (ALBs) also apply to the Director VM for AWS deployments.

Ops Manager v2.2.9 uses the following component versions:

| Component | Version |
|----------------|----------------|
| Ops Manager | 2.2-build.359* |
| Stemcell | 3586.52* |
| BBR SDK | 1.6 |
| BOSH Director | 266.13 |
| BOSH DNS | 1.10.0 |
| Metrics Server | 0.0.21 |
| CredHub | 1.9.3 |
| | |

| Syslog Component | Version |
|---|---------|
| UAA | 57.6* |
| AWS CPI | 70 |
| Azure CPI | 35.4 |
| GCP CPI | 27.0.1 |
| OpenStack CPI | 38 |
| vSphere CPI | 50 |
| * Components marked with an asterisk are updated. | |

2.2.8

- **[Security Fix]:** Bumps stemcell to 3586.48 to address [USN-3777-2](#).
- **[New Feature]:** Operators can tune the swap size as a percent of total memory size per instance group.
- **[Bug Fix]:** Bumps Azure CPI up to 35.4 to fix `LockTimeoutError` issues.
- **[Bug Fix]:** Operators can change the Director Hostname without losing connection between BOSH Director and VMs.
- **[Bug Fix]:** Stemcells no longer accidentally downgrade when upgrading to a new Ops Manager. This rare bug occurred when a product had a newer stemcell patch than Ops Manager included during the upgrade.
- **[Bug Fix]:** Operators can work around an expired SAML service provider cert by disabling and enabling SAML.
- **[Feature Improvement]:** The expiring certificates endpoint (`/api/v0/deployed/certificates`) now includes information about the SAML service provider cert.
- **[Feature Improvement]:** When you import products that use the future Unified Syslog feature, you are warned that some syslog features will not be active in this version of Ops Manager.
- **[Bug Fix]:** Dynamic JS pages now show the message from server-side errors instead of alert boxes with JavaScript errors (such as `[Object object]` or `t.filter()`).
- **[New Feature]:** You can now configure custom DNS handlers using the Ops Manager API.
- **[New Feature]:** You can now configure recursor timeouts using the Ops Manager API.

Ops Manager v2.2.8 uses the following component versions:

| Component | Version |
|---|----------------|
| Ops Manager | 2.2-build.339* |
| Stemcell | 3586.48* |
| BBR SDK | 1.6 |
| BOSH Director | 266.13* |
| BOSH DNS | 1.10.0 |
| Metrics Server | 0.0.21 |
| CredHub | 1.9.3 |
| Syslog | 11.3 |
| UAA | 57.4 |
| AWS CPI | 70 |
| Azure CPI | 35.4 |
| GCP CPI | 27.0.1 |
| OpenStack CPI | 38 |
| vSphere CPI | 50 |
| * Components marked with an asterisk are updated. | |

2.2.7

- **[Bug Fix]:** You are now only prompted to unlock Ops Manager once when enabling [Rescue Mode](#).
- **[Bug Fix]:** Ops Manager sets the storage account type and Director ephemeral disk correctly for Azure deployments.

Ops Manager v2.2.7 uses the following component versions:

| Component | Version |
|---|----------------|
| Ops Manager | 2.2-build.334* |
| Stemcell | 3586.43* |
| BBR SDK | 1.6 |
| BOSH Director | 266.12 |
| BOSH DNS | 1.10.0* |
| Metrics Server | 0.0.21 |
| CredHub | 1.9.3 |
| Syslog | 11.3 |
| UAA | 57.4 |
| AWS CPI | 70 |
| Azure CPI | 35.4* |
| GCP CPI | 27.0.1 |
| OpenStack CPI | 38 |
| vSphere CPI | 50 |
| * Components marked with an asterisk are updated. | |

2.2.6

- **[Feature]:** Operators can rotate BOSH DNS healthiness certificates to a new certificate authority (CA) that is valid for four years.
- **[UI Enhancement]:** An error message appears when Ops Manager fails to import an installation.
- **[UI Enhancement]:** An error message appears when a file downloaded from Pivotal Network is invalid or corrupt.

Ops Manager v2.2.6 uses the following component versions:

| Component | Version |
|---|----------------|
| Ops Manager | 2.2-build.319* |
| Stemcell | 3586.40 |
| BBR SDK | 1.6 |
| BOSH Director | 266.12* |
| BOSH DNS | 1.8 |
| Metrics Server | 0.0.21 |
| CredHub | 1.9.3 |
| Syslog | 11.3 |
| UAA | 57.4 |
| AWS CPI | 70 |
| Azure CPI | 35.2 |
| GCP CPI | 27.0.1 |
| OpenStack CPI | 38 |
| vSphere CPI | 50 |
| * Components marked with an asterisk are updated. | |

2.2.5

- **[Feature]:** New CAs for BOSH DNS healthiness and DNS API apply automatically on upgrade. These CAs are valid for four years.
- **[Feature]:** All DNS healthiness certificates are signed by a Credhub CA.
- **[Feature]:** Operators can rotate DNS healthiness certificates using `POST/api/v0/certificate_authorities/active/regenerate`.
- **[Feature Improvement]:** Ops Manager API warns you when you attempt to regenerate certificates without first applying changes to propagate CA

changes.

- **[Bug Fix]:** Verifiers work in vCenter v6.7. Fixes the [Ops Manager “Required Datacenter privileges” Error on vSphere](#) known issue.

Ops Manager v2.2.5 uses the following component versions:

| Component | Version |
|---|----------------|
| Ops Manager | 2.2-build.316* |
| Stemcell | 3586.40 |
| BBR SDK | 1.6 |
| BOSH Director | 266.10 |
| BOSH DNS | 1.8 |
| Metrics Server | 0.0.21 |
| CredHub | 1.9.3 |
| Syslog | 11.3 |
| UAA | 57.4 |
| AWS CPI | 70 |
| Azure CPI | 35.2 |
| GCP CPI | 27.0.1 |
| OpenStack CPI | 38 |
| vSphere CPI | 50 |
| * Components marked with an asterisk are updated. | |

2.2.4

- **[Security Fix]:** Bumps stemcell to 3586.40.
- **[Bug Fix]:** Pivotal Network integrates successfully with Pivotal Application Service (PAS) tile and Small Footprint PAS.
- **[Feature Improvement]:** You can use the Ops Manager API to delete individual OpenStack or vCenter Configs. For more information, see [Deleting IaaS Configuration](#) [↗](#) in the Ops Manager API documentation.
- **[Bug Fix]:** You cannot import an installation with no deployed products.

Ops Manager v2.2.4 uses the following component versions:

| Component | Version |
|---|---------------|
| Ops Manager | 2.2-build.312 |
| Stemcell | 3586.40* |
| BBR SDK | 1.6 |
| BOSH Director | 266.10 |
| BOSH DNS | 1.8 |
| Metrics Server | 0.0.21* |
| CredHub | 1.9.3 |
| Syslog | 11.3 |
| UAA | 57.4 |
| AWS CPI | 70 |
| Azure CPI | 35.2 |
| GCP CPI | 27.0.1 |
| OpenStack CPI | 38 |
| vSphere CPI | 50 |
| * Components marked with an asterisk are updated. | |

2.2.3

- **[Security Fix]:** Bumps stemcell to 3586.36

Ops Manager v2.2.3 uses the following component versions:

| Component | Version |
|---|---------------|
| Ops Manager | 2.2-build.304 |
| Stemcell | 3586.36* |
| BBR SDK | 1.6 |
| BOSH Director | 266.10* |
| BOSH DNS | 1.8* |
| Metrics Server | 0.0.17 |
| CredHub | 1.9.3 |
| Syslog | 11.3 |
| UAA | 57.4 |
| AWS CPI | 70 |
| Azure CPI | 35.2 |
| GCP CPI | 27.0.1* |
| OpenStack CPI | 38 |
| vSphere CPI | 50 |
| * Components marked with an asterisk are updated. | |

2.2.2

- **[Bug Fix]:** Fixes Xenial stemcell upload issue. This resolves [Error When Importing Xenial Stemcell](#).

Ops Manager v2.2.2 uses the following component versions:

| Component | Version |
|---|----------------|
| Ops Manager | 2.2-build.300* |
| Stemcell | 3586.27* |
| BBR SDK | 1.6 |
| BOSH Director | 266.8.0* |
| BOSH DNS | 1.6 |
| CredHub | 1.9.3 |
| Syslog | 11.3 |
| UAA | 57.4 |
| AWS CPI | 70 |
| Azure CPI | 35.2 |
| GCP CPI | 27 |
| OpenStack CPI | 38 |
| vSphere CPI | 50 |
| * Components marked with an asterisk are updated. | |

2.2.1

- **[Bug Fix]:** Fixes critical manifest generation grammar issue.
- **[Bug Fix]:** You can now delete an unused AZ in an installation after clicking **Apply Changes**.
- **[Bug Fix]:** Certain VM image components no longer write to the persistent disk after reboot.
- **[Bug Fix]:** Ops Manager now verifies certificates successfully when connecting to S3 blobstores with TLS. This resolves a [known issue](#) in Ops Manager

v2.2.0. For more information, see [Operations Manager Validation returns TLS error when configuring Bosh Director S3 blobstore](#).

- **[Security Fix]:** Bumps Nokogiri to 1.8.4 to remediate [CVE-2017-15412](#).
- **[Feature Improvement]:** Installation Dashboard and deployment status pages may load more quickly.

Ops Manager v2.2.1 uses the following component versions:

| Component | Version |
|---|---------------|
| Ops Manager | 2.2-build.296 |
| Stemcell | 3586.25* |
| BBR SDK | 1.6 |
| BOSH Director | 266.6* |
| BOSH DNS | 1.6 |
| CredHub | 1.9.3 |
| Syslog | 11.3 |
| UAA | 57.4* |
| AWS CPI | 70 |
| Azure CPI | 35.2 |
| GCP CPI | 27 |
| OpenStack CPI | 38 |
| vSphere CPI | 50 |
| * Components marked with an asterisk are updated. | |

2.2.0

Ops Manager v2.2.0 uses the following component versions:

| Component | Version |
|---------------|---------|
| Stemcell | 3586.24 |
| BBR SDK | 1.6 |
| BOSH Director | 266.5 |
| BOSH DNS | 1.6 |
| CredHub | 1.9.3 |
| Syslog | 11.3 |
| UAA | 57.3 |
| AWS CPI | 70 |
| Azure CPI | 35.2 |
| GCP CPI | 27 |
| OpenStack CPI | 38 |
| vSphere CPI | 50 |

New Features in Ops Manager v2.2

Ops Manager v2.2 includes the following major features:

Multiple Data Centers on vSphere

Ops Manager now allows you to configure multiple vSphere vCenters to a single BOSH Director.

You can add additional data centers in the **vSphere Config** pane of your vSphere BOSH Director tile. For more information about how to add, edit, and delete vCenters, see [Managing Multiple vSphere vCenters](#).

Note: If you use the Ops Manager API and multiple vSphere configs exist, the GET HTTP request for Director properties omits the `iaas_configuration` key.

Selectively Deploy Tiles in Ops Manager or by an API Endpoint

You can now choose to deploy a selection of tiles rather than all tiles in Ops Manager. If you choose to selectively deploy your environment, you can drastically reduce the time to **Apply Changes**. This feature is ideal to limit updates to one or more tiles, which reduces the amount of change in any given deployment.

To access this feature, click **Review Pending Changes** underneath the **Apply Changes** button in the Ops Manager Installation Dashboard. For more information, see [Reviewing Pending Changes with Ops Manager](#).

In the Ops Manager UI, this feature is in beta. It is generally available as an API endpoint. To selectively deploy tiles using the API, send a POST to `/api/v0/installations`. For more information, see [Triggering an install process](#) in the Ops Manager API documentation.

Warning: Do not selectively deploy tiles when upgrading to PCF v2.2. Instead, redeploy all product tiles using **Apply Changes** on the Ops Manager Installation Dashboard. For more information, see [Redeploy All Products After Upgrading to Ops Manager v2.2](#).

Note: Ops Manager is soliciting feedback for this feature. Submit feedback through your product architect or directly by emailing opsmanager-feedback+selective_deploys@pivotal.io.

Ops Manager Stores Past Manifests

Through the Ops Manager API, you can see Ops Manager's manifest history. Manifest history is helpful for running `diff` commands on manifests to see changes over time.

For this feature, use the following Ops Manager API endpoints:

- `/api/v0/installations/:installation_id/products/:product_guid/manifest`: For more information, see [Getting BOSH manifests from historical installations](#) from the Ops Manager API documentation.
- `/api/v0/installations`: For more information, see [Getting a list of recent install events](#) from the Ops Manager API documentation.

Azure Stack is Generally Available

Pivotal officially supports Azure Stack.

Azure Stack is a hybrid cloud platform that lets you deliver Azure services from your own on-premise datacenter. For more information about Azure Stack, see [What is Azure Stack?](#) from the Microsoft Azure documentation.

You can configure Azure Stack through the **BOSH Director for Azure** tile. For more information about Azure Stack-specific configurations, see the steps in the [Azure Config Page](#) section of the *Configuring BOSH Director on Azure* topic.

Ops Manager Supports Azure China

Ops Manager now supports a special region in Azure called Azure China. Azure China is a physically separated instance of cloud services that is located in China and independently operated. For more information about Azure China, see [What is Azure China 21Vianet?](#) in the Azure China documentation.

To tell the BOSH Director that you are using an Azure China environment, go to the **BOSH Director for Azure** tile and select `Azure China Cloud` from the **Azure Environment** field. For more information, see [Azure Config Page](#) in the *Configuring Ops Manager on Azure* manual installation topic.

Ops Manager Credentials Stored in CredHub

On each **Apply Changes**, Ops Manager sends your user-specified credentials to BOSH CredHub. This feature offers greater security for your credentials. For more information about where Ops Manager stores your credentials, see [BOSH CredHub](#).

For information about how this feature affects tile authors, see [PCF v2.2 Partners Release Notice](#) in the *PCF Tile Developer Guide*.

Multi-Line Credentials

Ops Manager v2.2 now supports text areas for any type of multi-line credential. If you want a `secret` property to use a text area instead of the default single-line text field, you must set `display_type` to `text_area` in the `property_inputs` section of your property blueprint, as in the example below.

```
property_inputs:
- reference: secret_meaning
  label: 'Secret Meaning'
  description: 'If you play it backwards...!'
  display_type: 'text_area'
```

For more information, see the [Custom Forms and Properties](#) section of the *Tile Generator* topic.

Specify a Custom Trusted SSL Certificate

Operators can specify a custom trusted SSL certificate and key for the Ops Manager server so that traffic isn't exposed to man-in-the-middle attacks when using Ops Manager.

By default, Ops Manager uses an auto-generated self-signed certificate. To change this configuration to your own SSL certificate, navigate to **Settings** from the Ops Manager Installation Dashboard and select the **SSL Certificate** pane to enter your **Certificate** and **Private Key**.

For more information about navigating the Ops Manager Settings page, see [Settings Page](#) in the *Understanding the Ops Manager Interface* topic.

 **Note:** Custom SSL certificate and key is persisted between upgrades. Custom SSL only needs a one-time configuration.

Delete Your Pivotal Network API Token

You can now delete your Pivotal Network API token, along with the Pivotal Network release dashboard and all of the tile metadata from Pivotal Network products.

For more information, see [Settings Page](#) in the *Understanding the Ops Manager Interface* topic.

Configure an Ops Manager Syslog Server

You can configure a syslog server for Ops Manager logs. Logs include rails production logs, audit logs, UAA logs, nginx logs, and upstart logs for Ops Manager processes as well as additional log types. Previous to this change, Ops Manager logs were not centralized in one accessible location. You also have the option to TLS-encrypt your logs.

To configure syslog for Ops Manager, go to **Syslog** from Ops Manager **Settings**, select **Yes** to enable syslog and fill the required fields. Only administrators can view the Syslog pane.

For more information about configuring syslog for Ops Manager, see [Settings Page](#) in the *Understanding the Ops Manager Interface* topic.

 **Note:** When you enter your syslog credentials, Ops Manager does not validate them. You should test your syslog server to ensure that the credentials were entered correctly and the server is receiving Ops Manager logs.

 **Breaking Change:** If you were running scripts to get Ops Manager logs, those scripts break on upgrade to Ops Manager v2.2 and later.

Xenial Stemcell Upgrade Support

As of April 2019, Trusty stemcells will no longer receive support, nor will Pivotal have CVE patches for them. Ops Manager v2.2 allows tile authors to upgrade from Trusty stemcells to Xenial stemcells.

TLS for Internal Blobstore Supported

Ops Manager now supports TLS communications if you choose to use an internal blobstore.

To enable internal blobstore TLS communication, all of your tiles must have stemcell v3586 or later. You can configure internal TLS by clicking **Enable TLS** in the **Director Config** pane of the BOSH Director tile.

Custom TLS Certificate for External MySQL Database Supported

Ops Manager now allows you to configure a custom TLS certificate for an external MySQL database.

To configure a custom TLS certificate, navigate to **Director Config > Database Location** and select **External MySQL Database** to fill in the relevant fields.

 **Note:** You must select **Enable TLS for Director Database** to configure the TLS-related fields.

For more information, see the **Director Config Page** section of the [Ops Manager Director installation topic for your IaaS](#).

UI Improvements to Installation Dashboard

The following lists UI changes to the Ops Manager Installation Dashboard:

- **Stemcell Library** is persistently in the page header. You can now access Stemcell Library from anywhere in Ops Manager.
- **Changelog** is persistently in the page header. You can now access the changelog from anywhere in Ops Manager.
- **Review Pending Changes BETA** button is below **Apply Changes**. For more information about this feature, see [Selectively Deploy Ops Manager Tiles](#).
- **Azure Logo** is updated.
- **BOSH Director tile name** is changed to “BOSH Director for YOUR_IaaS”.
- **Changelog** page shows tiles which were not changed but were still deployed.

For more information about the Ops Manager UI, see [Installation Dashboard Page](#) in the *Understanding the Ops Manager Interface* topic.

Change Log Includes Products Deployed but Unchanged

The [Change Log](#) pane lists products as **Unchanged** when they remain deployed, but their configuration has not changed from a prior deployment, so Ops Manager did not re-deploy them.

More Detail Available By Ops Manager API Endpoint

A new API endpoint is available for Ops Manager. Send a `GET` to `/v0/staged/pending_changes` to see details about your Ops Manager installation, including tile names, errand names, build version, and deployment status. The API response will show information on all tiles, whether they are deployed or have pending changes.

For more information about setting up the Ops Manager API, see [Using the Ops Manager API](#).

Custom Identification Tags Supported

You can specify a single set of tags that apply to all VMs and disks for your foundation. Identification tags allow you to easily identify which foundation your VMs belong to when viewing your IaaS. You are able to set custom **Identification Tags** in the **Director Config** pane of your BOSH Director tile.

For more information about configuring identification tags, see the **Director Config Page** section of the [Ops Manager Director installation topic for your IaaS](#).

BOSH DNS Enabled By Default

BOSH DNS is enabled by default for both app containers and PCF components in PCF v2.2.

In previous versions, Consul managed service discovery between PCF components, but Consul is being replaced by BOSH DNS.

 **Note:** In PCF v2.2, Consul and BOSH DNS are both available in PCF, but BOSH DNS is the only service used for DNS requests.

You can disable BOSH DNS if instructed to do so by Pivotal support. If you disabled BOSH DNS in PCF v2.1, reenable it before upgrading to PCF v2.2. For more information, see [BOSH DNS Enabled By Default](#).

 **warning:** Do not disable BOSH DNS without instructions from Pivotal support. Disabling BOSH DNS will also disable PKS, NSX-T, and several PAS features.

“When Changed” Errand Setting Removed

Ops Manager no longer includes a **When Changed** option for tile errands. In the **Errands** pane for a given tile, you can set errands **On** to run them or **Off** to not run them. The default setting is **On**.

Known Issues

 **warning:** Ops Manager v2.2 is not supported by PKS starting in PKS v1.3. Use a later version of Ops Manager if you wish you use PKS v1.3.

DNS Server Hangs or DNS Lookups Fail

With BOSH DNS, every BOSH-deployed VM has a DNS server. In large PCF installations, this DNS server may hang or DNS lookups may fail when the VM experiences too many DNS lookups in a short amount of time.

This error is caused by a race condition and deadlock in the VM's DNS server.

To fix this problem, run `monit` on the VM with failing DNS to restart its `bosh-dns` process.

Error When Importing Xenial Stemcell

Ops Manager v2.2.0 and later support Xenial stemcells. However, the Ops Manager UI returns an error when you attempt to import a Xenial stemcell.

As a workaround, you can upload the stemcell and assign it to a product using the [Ops Manager API](#).

This issue is fixed in Ops Manager v2.2.2.

Ops Manager Validation Returns TLS Error When Configuring BOSH Director S3 Blobstore

If a remote S3 blobstore uses a privately signed SSL certificate, operators see an error when configuring the BOSH Director to use an S3 blobstore.

The error reads:

```
SSL_connect returned=1 errno=0 state=SSLv3 read server certificate B: certificate verify failed (OpenSSL::SSL::SSLError) Unable to verify certificate. This may be an issue with the remote host or with Excon. Excon has certificates bundled, but these can be customized:
```

This error appears because Ops Manager attempts to validate the S3 blobstore by testing the SSL certificate. Ops Manager does not use trusted certificates to make this connection, so the connection fails.

A workaround is available for this issue. Operators can install the public CA certificate directly into the OS config of Ops Manager by following these steps:

1. SSH into the Ops Manager VM.
2. Copy the public CA certificate into `/etc/ssl/certs`.
3. Run `sudo update-ca-certificates -f -v`. This installs the new CA certificate.

Upon successful execution, “1 added” displays in the output. For example:

```
Updating certificates in /etc/ssl/certs... 1 added, 0 removed;
done.
```

This indicates the new certificate is installed.

For more information, see the Knowledge Base article [Operations Manager Validation Returns TLS Error When Configuring BOSH Director S3 Blobstore](#).

Ops Manager Deployment Fails Because Monit Reports Job as Failed

This issue causes Ops Manager deployments to fail with an error indicating one or more jobs are not running after an update.

The error reads:

```
Error: 'cloud_controller/6632bf71-7493-4383-a3f9-9401bafb4710 (1)' is not running after update. Review logs for failed jobs:
cloud_controller_ng
```

Additionally, when you SSH into a VM and run `monit summary`, monit reports jobs as “Execution Failed”.

To remediate this issue, use monit to restart the affected processes.

For more information, see the Knowledge Base article [Deployment Fails Because Monit Reports Job as Failed](#).

Ops Manager “Required Datacenter privileges” Error on vSphere

Ops Manager on vSphere v6.7 fails with an error message: “Could not log in: Required Datacenter privileges could not be verified: SystemError: A general system error occurred: Authorize Exception”

You can ignore this error message. Click “Ignore errors and start the install” to authenticate.

This issue is fixed in Ops Manager v2.2.5 and v2.3.0 or later.

Pivotal Application Service v2.2 Release Notes

Pivotal Cloud Foundry is certified by the Cloud Foundry Foundation for 2019.

Read more about the [certified provider program](#) and the [requirements of providers](#).

Releases

2.2.16

- **[Security Fix]** Fix insecure gradle dependency in CredHub
- **[Bug Fix]** Allow persistent disk size on backup and restore to be configured
- Bump ubuntu-trusty-stemcell to version `3586.100`
- Bump cflinuxfs2 to version `1.283.0`
- Bump credhub to version `1.9.12`

| Component | Version |
|-----------------------------------|----------|
| ubuntu-trusty-stemcell | 3586.100 |
| backup-and-restore-sdk | 1.12.0 |
| binary-offline-buildpack-lts | 1.0.30 |
| bosh-dns-aliases | 0.0.2 |
| bosh-system-metrics-forwarder | 0.0.15 |
| capi | 1.58.16 |
| cf-autoscaling | 201.11 |
| cf-backup-and-restore | 0.0.11 |
| cf-cli | 1.5.0 |
| cf-mysql | 36.16.0 |
| cf-networking | 2.3.3 |
| cf-smoke-tests | 40.0.40 |
| cf-syslog-drain | 6.8 |
| cflinuxfs2 | 1.283.0 |
| consul | 195 |
| credhub | 1.9.12 |
| diego | 2.8.7 |
| dotnet-core-offline-buildpack-lts | 2.2.5 |
| garden-runc | 1.16.8 |
| go-offline-buildpack-lts | 1.8.33 |
| haproxy | 8.7.0 |
| java-offline-buildpack-lts | 4.16.1 |
| log-cache | 1.4.7 |
| loggregator | 102.8 |
| mysql-monitoring | 8.20.0 |
| nats | 24 |

2.2.14

- **[Security Fix]** Bump UAA to address CVE-2019-3775
- **[Feature Improvement]** Improve error messages when installing buildpacks
- **[Feature Improvement]** Increase performance for internal MySQL by setting the setting for `innodb_flush_log_at_trx_commit` from 1 to 2. This increases performance safely for clustered deployments. Single node might need to scale up to avoid the possibility of 1 second of data loss during deploys.
- **[Feature Improvement]** Add support for tcp hitless reloads in haproxy to avoid connection reset errors
- **[Feature Improvement]** Add ability to enable/disable gorouter hairpinning with **Bypass security checks for route service lookup**. This feature has potential security concerns, but may be needed for backwards compatibility. See [Configuring Route Service Lookup](#).
- **[Bug Fix]** Fix issue in which Apps Manager shows `Invalid User` as the username for space and organization members without usernames, such as UAA clients
- Bump ubuntu-trusty stemcell to version `3586.93`
- Bump capi to version `1.58.15`
- Bump cf-autoscaling to version `201.10`
- Bump cf-syslog-drain to version `6.8`
- Bump cflinuxfs2 to version `1.279.0`
- Bump push-apps-manager-release to version `665.0.30`
- Bump routing to version `0.178.7`
- Bump uaa to version `60.13`

2.2.12

- **[Security Fix]** Apps Manager verifies SSL certificates for endpoints to which it proxies. For environments using untrusted certificates, this may cause Apps Manager to show no content. To resolve this issue, see [Apps Manager shows no content due to SSL validation issue](#).
- **[Feature Improvement]** Increase the maximum number of connections for internal MySQL to 3500
- **[Feature Improvement]** Change default lifetime of Apps Manager client UAA token to 1 hour

- [Feature Improvement] Improve auctioneer cell-state logs in Diego Auctioneer
- [Feature Improvement] Increase Tomcat max http header size to 14K
- [Bug Fix] Fix BBR failures when backing up large blobs to unversioned S3 blobstores
- [Bug Fix] Fix binding route services to apps
- [Bug Fix] Fix concurrency bug in the Router's route pool, which could manifest as a fatal error: "Unlock of unlocked RWMutex"
- [Bug Fix] Fix bug in Apps Manager where space page, services tab shows a 500 error if the last operation of a service is null
- [Bug Fix] Make header tabs focusable and clickable via keyboard navigation in Apps Manager
- [Bug Fix] Improve garden init process to avoid edge cases that can lead to zombies
- [Bug Fix] Add back Consul registration in PXC Proxy to fix issue that can cause API and Application downtime when upgrading from PAS 2.1.x.
- [Bug Fix] Show (Deleted User) in Apps Manager rather than empty row for Cloud Controller users that do not exist in UAA
- [Bug Fix] Fix failure to bind service to app with custom parameters in Apps Manager
- opsmanager failed to upgrade srt 2.1 to 2.2
- Bump ubuntu-trusty-stemcell to version 3586.71
- Bump backup-and-restore-sdk to version 1.12.0
- Bump binary-offline-buildpack-lts to version 1.0.30
- Bump capi to version 1.58.11
- Bump cflinuxfs2 to version 1.260.0
- Bump diego to version 2.8.7
- Bump dotnet-core-offline-buildpack-lts to version 2.2.5

2.2.11

⚠ warning: Do not upgrade directly to this release from PAS v2.1.x. For more information, see [Downtime when Upgrading from v2.1 to v2.2.7 or Later](#).

- **[Security Fix]** Upgrade UAA to 60.9 to address CVE-2018-15754
- **[Feature Improvement]** Improved logging and error handling for Diego Sync job
- **[Feature Improvement]** Blobstore pre-start performance enhancement
- **[Bug Fix]** Remove log noise from Reverse Log Proxy and TrafficController
- **[Bug Fix]** Fix memory allocated to be multiplied by number of instances for each process on space page app tab
- **[Bug Fix]** Ensure that the encoding used by Credhub is UTF-8
- **[Bug Fix]** VXLAN-policy-agent now opens ports in non-ephemeral port range
- **[Bug Fix]** Fix help text for TCP router ports because comma separated lists of ports are not supported
- **[Bug Fix]** Ensure logs and metrics are forwarded by adding syslog_forwarder and loggregator_agent to VMs missing them
- Bump ubuntu-trusty-stemcell to version `3586.60`

- [Security Fix] log-cache no longer supports TLS 1.0 and TLS1.1
- [Feature Improvement] Split up networking policy server database migrations to reduce the risk of a failure causing a partial migration
- [Feature Improvement] Improve error messages logged by Cloud Controller when there are Azure blobstore failures
- [Feature Improvement] Update name of the Small Footprint PAS tile shown on the tile in Ops Manager UI
- [Feature Improvement] clock_global now defaults to 2 instances to be highly available
- [Feature Improvement] Allow disabling connection pooling for autoscaler API & escape special characters in external database passwords
- [Bug Fix] Prevent potential memory leak when Cloud Controller’s space summary endpoint is called under certain usage conditions
- [Bug Fix] Fix manual configuration of load balancers for SSH to application containers on Small Footprint PAS (SF-PAS)
- Bump ubuntu-trusty stemcell to version 3586.46
- Bump capi to version 1.58.7
- Bump cf-autoscaling to version 201.8
- Bump cf-networking to version 2.3.1
- Bump cf-smoke-tests to version 40.0.10
- Bump cflinuxfs2 to version 1.242.0
- Bump diego to version 2.8.4
- Bump go-offline-buildpack-lts to version 1.8.28
- Bump java-offline-buildpack-lts to version 4.16.1
- Bump log-cache to version 1.4.7
- Bump ruby-offline-buildpack-lts to version 1.7.24

2.2.7

⚠ warning: Do not upgrade directly to this release from PAS v2.1.x. For more information, see [Downtime when Upgrading from v2.1 to v2.2.7 or Later](#).

- **[Security Fix]** Bump garden-runc to prevent malicious users from causing a denial of service for other apps
- **[Feature Improvement]** Improve nfs blobstore pre-start performance
- **[Bug Fix]** space and org managers can now view app logs in apps manager
- **[Bug Fix]** Fix unsafe logic in NFS unmount and drain code that may lead to deletion of files on remote NFS shares.
- **[Bug Fix]** PAS 2.1.14 upgrade fails with `Error: release 'cf-networking/1.10.2' has already been uploaded`
- **[Bug Fix]** Fix issue in loggregator where AZ names with special characters could cause metron agent job to fail
- **[Bug Fix]** Fix issue where the PAS tile could be incorrectly downloaded when upgrading SF-PAS via PivNet
- **[Bug Fix]** Fix parse error for syslog rules when iptables logging is enabled
- Bump binary-offline-buildpack-lts to version `1.0.27`
- Bump capi to version `1.58.5`
- Bump cf-cli to version `1.5.0`
- Bump cf-smoke-tests to version `40.0.9`
- Bump cf-syslog-drain to version `6.6`
- Bump cflinuxfs2 to version `1.238.0`
- Bump dotnet-core-offline-buildpack-lts to version `2.1.5`
- Bump garden-runc to version `1.16.1`
- Bump go-offline-buildpack-lts to version `1.8.27`
- Bump java-offline-buildpack-lts to version `4.15.1`
- Bump loggregator to version `102.7`
- Bump nfs-volume to version `1.2.3`
- Bump nodejs-offline-buildpack-lts to version `1.6.32`
- Bump php-offline-buildpack-lts to version `4.3.61`

- Bump push-apps-manager-release to version `665.0.19`
- Bump pxc to version `0.14.0`
- Bump python-offline-buildpack-lts to version `1.6.21`
- Bump ruby-offline-buildpack-lts to version `1.7.23`
- Bump staticfile-offline-buildpack-lts to version `1.4.32`
- Bump stemcell ubuntu-trusty to version `3586.43`

| Component | Version |
|-------------------------------|----------|

2.2.6

- **[Security Fix]** Prevent app developers from registering an NFS service broker that issues service bindings with uid and gid specified when LDAP is enabled
- **[Feature Improvement]** Update BOSH DNS configuration to allow resolving BBS and Auctioneer servers on unhealthy VMs
- **[Feature Improvement]** Operators can configure the maximum number of packages and droplets to store
- **[Feature Improvement]** Operators can override connection timeout values for the cloud controller database to prevent downtime when MySQL proxy VMs are recreated
- **[Feature Improvement]** Update PAS 2.2 with binary-buildpacks that have stack associations
- **[Bug Fix]** Fix issue where the SF-PAS tile could be incorrectly downloaded when upgrading PAS via PivNet
- **[Bug Fix]** Improve performance to reduce chance of failed database migrations during upgrades of usage service
- **[Bug Fix]** Fixes and improvements for Apps Manager
 - When the Autoscaler is not installed, prevent a crash that occurs on the app page
 - When creating a space as admin, make the admin a member of the corresponding organization
 - Improved the display of service plan costs when costs are not integers as expected
 - Prevent a page crash that occurs when there are no upcoming scheduled limit changes
- Bump binary-offline-buildpack to version [1.0.25](#)
- Bump push-apps-manager-release to version [665.0.18](#)
- Bump push-usage-service-release to version [666.0.11](#)
- Bump stemcell ubuntu-trusty to version [3586.42](#)

| Component | Version |

2.2.5

- **[Security Fix]** Bump usage service for CVE-2018-11086
- **[Security Fix]** Bump apps manager for CVE-2018-11088
 - Fix security vulnerability: CVE-2018-11088
 - Fix typo in autoscaling flyout
 - Text changes to improve actuator integration with Steeltoe
 - Steeltoe heap dumps should have extension .dmp
 - Fix Spring endpoints not appearing in app actions dropdown for Spring 2.0 apps
 - Fix Spring “View Raw JSON” feature not appearing when git info not present on app
 - Fix occasionally incorrect display of app processes when scaling app memory or disk
 - Fix app remaining in “Starting...” state after scaling
 - Fix autoscale instance limits not refreshing in flyout after applying changes
- **[Bug Fix]** Autoscaler uses https to communicate with log-cache instead of http
- **[Bug Fix]** Configure PXC MySQL to listen on port that will not conflict with processes that get a random port (Small Footprint Only)
 - Change MySQL from listening on port 33306 to 13306 for Small Footprint PAS
- **[Feature Improvement]** Do not back up resources bucket as it is not restored
 - The property `.properties.system_blobstore.external.resources_bucket.value` has been deprecated and will be removed in 2.3
- Bump bosh-system-metrics-forwarder to version `0.0.15`
- Bump cf-autoscaling to version `201.3`
- Bump cf-smoke-tests to version `40.0.8`
- Bump cflinuxfs2 to version `1.235.0`
- Bump log-cache to version `1.4.4`
- Bump pivotal-account to version `1.9.1`
- Bump push-apps-manager-release to version `665.0.17`
- Bump push-usage-service-release to version `666.0.10`
- Bump routing to version `0.178.3`

- Bump stemcell ubuntu-trusty to version 3586.40

| Component | Version |
|---|----------|
| stemcell | 3586.40 |
| backup-and-restore-sdk | 1.7.1 |

2.2.4

- [Feature Improvement] Improve performance for `nfs-experimental` readonly mounts and those that don't set the uid and gid parameters
- [Bug Fix] Fix autoscaler and smoke test failures when using database with timezone setting other than UTC
- [Bug Fix] Fixes BBS communication with Locket issue on startup when deploying with BOSH DNS enabled
- [Bug Fix] Apps manager: Fix spaces count on org page
- [Bug Fix] Apps manager: When the autoscaler service fails to toggle, show an error flash message
- [Bug Fix] Apps manager: A spacedeveloper can map a route without providing a hostname
- [Bug Fix] Apps manager: Fix crash on app page overview tab when spring health endpoint returns an array of objects instead of an array of strings
- Bump cf-autoscaling to version `201.1`
- Bump cf-smoke-tests to version `40.0.6`
- Bump cflinuxfs2 to version `1.229.0`
- Bump diego to version `2.8.2`
- Bump log-cache to version `1.3.0`
- Bump nfs-volume to version `1.2.2`
- Bump push-apps-manager-release to version `665.0.14`
- Bump routing to version `0.178.2`
- Bump stemcell to version `3586.27`

2.2.3

- **[Feature Improvement]** Loggregator agent egresses preferred tags instead of DeprecatedTags in loggregator envelopes. This fixes a high CPU issue in Doppler cluster.
- **[Feature Improvement]** Fix issue where fileserver assets were not correctly invalidated in Diego cell caches after an upgrade
- **[Feature Improvement]** `capi` `/v2/info` endpoint returns additional metadata for `name`, `build` and `description`
- **[Feature Improvement]** Add the `healthwatch_api_admin` UAA client to allows access to the Healthwatch API
- **[Feature Improvement]** Retry blobstore uploads when GCS returns transmission error
- **[Feature Improvement]** Allow operators to configure application health check timeout in PAS
- **[Feature Improvement]** Move encryption key field to the top of the Credhub page
- **[Bug Fix]** Fix TLS pruning behavior for Gorouter
- **[Bug Fix]** Apps using a Docker image from an insecure registry configured in the Private Docker Insecure Registry Whitelist can now be staged successfully.
- **[Bug Fix]** Fix option “HAProxy requests but does not require client certificates.”
- **[Bug Fix]** Bump apps manager with changes
 - When creating new services, no longer show org-scoped services from other organizations
 - Org Managers and Admins can leave organizations
 - When visiting Apps Manager on an environment where UAA has a self-signed SSL cert, do not blue screen, redirect to UAA login page.
- **[Bug Fix]** Fix performance and data consistency issues in Log Cache.
- **[Bug Fix]** Set cloud controller staging timeout value on all cloud controller jobs to allow large apps to stage before the timeout.
- Bump capi to version `1.58.4`
- Bump diego to version `2.8.1`
- Bump java-offline-buildpack to version `4.13.1`
- Bump log-cache to version `1.4.0`
- Bump loggregator to version `102.4`
- Bump mysql-monitoring to version `8.20.0`
- Bump push-apps-manager-release to version `665.0.13`

2.2.1

- **[Feature Improvement]** Allows PCF Metrics to be installed with both v1.5 and v1.4 versions to prevent dataloss.
- **[Bug Fix]** Bump cf-smoke-tests-release to 40.0.5 to fix some flakiness
- **[Security Fix]** Bump apps manager for CVE-2018-11044
 - When creating new services, no longer show org-scoped services from other organizations
 - Org Managers and Admins can leave organizations
- **[Security Fix]** Bump loggregator release for CVE-2018-1268 and CVE-2018-1269
- ***** [Bug Fix]**** bump consul to v195
 - Includes go 1.9.7, removes go 1.8.*.
 - Deploying v193 could fail on some deployments due to a conflict with other tiles that compiled the release differently
 - Fixes intermittent consul DNS issues on Windows Cells
- Bump binary-offline-buildpack to version 1.0.21
- Bump cf-smoke-tests to version 40.0.5
- Bump cflinuxfs2 to version 1.223.0
- Bump consul to version 195
- Bump dotnet-core-offline-buildpack to version 2.1.3
- Bump go-offline-buildpack to version 1.8.25
- Bump loggregator to version 102.2
- Bump nodejs-offline-buildpack to version 1.6.28
- Bump php-offline-buildpack to version 4.3.57
- Bump push-apps-manager-release to version 665.0.11
- Bump python-offline-buildpack to version 1.6.18
- Bump ruby-offline-buildpack to version 1.7.21
- Bump staticfile-offline-buildpack to version 1.4.29

| Component | Version |

How to Upgrade

The procedure for upgrading to Pivotal Application Service (PAS) v2.2 is documented in the [Upgrading Pivotal Cloud Foundry](#) topic.

When upgrading to v2.2, be aware of the following upgrade considerations:

- If you previously used an earlier version of PAS, you must first upgrade to PAS v2.1 to successfully upgrade to PAS v2.2.
- Some partner service tiles may be incompatible with PCF v2.2. Pivotal is working with partners to ensure their tiles are updated to work with the latest versions of PCF.

For information about which partner service releases are currently compatible with PCF v2.2, review the appropriate partners services release documentation at <https://docs.pivotal.io>, or contact the partner organization that produces the tile.

New Features in PAS v2.2

More Secure Cipher Suites for CF SSH Proxy

The CF SSH proxy accepts a narrower range of ciphers, MACs, and key exchanges. This change improves the security of CF SSH sessions.

These SSH proxy settings are not configurable in the PAS tile.

Note: This change may be incompatible with SSH clients other than `cf ssh`. See [SSH Proxy Security Configuration](#) for more information about the supported ciphers, MACs, and key exchanges.

TLS-Encrypted Option for Internal System Databases

For internal system databases, PAS now supports a more secure [Percona Server](#) database with TLS-encrypted communication between server nodes, as well as the previous [MariaDB](#) option. See [Migrate to TLS Communication](#) for details.

 **Warning:** Migrating PAS internal databases to using TLS causes temporary downtime of PAS system functions. It does not interrupt apps hosted by PAS.

Support for AWS Instance Profiles

PAS now supports [AWS instance profiles](#) when you are configuring an S3 filestore. Either an instance profile or an access and secret key are required.

For more information, see the **External or S3 Filestore** section of the [PAS installation topic for your IaaS](#).

Unversioned S3 Buckets for Backups

PAS can now back up unversioned S3 buckets used for external file storage, saving backup artifacts to separate, dedicated backup buckets. For more information, see the **External or S3 Filestore** section of the [PAS installation topic for your IaaS](#).

Gorouter Logging Changes for GDPR Compliance

Operators can now disable logging of client IP addresses in the Gorouter to comply with the General Data Protection Regulation (GDPR).

This setting, **Logging of Client IPs in CF Router**, is configured in the **Networking** pane of the PAS tile. You can disable logging of the `X-Forwarded-For` HTTP header only or of both the source IP address and the `X-Forwarded-For` HTTP header. By default, the **Log client IPs** option is set in PAS.

For more information about configuring the **Logging of Client IPs in CF Router** field, see the **Configure Networking** section of the [PAS installation topic for your IaaS](#).

New Format for Timestamps in Diego Component Logs

The timestamps in the Diego component logs are now in a format compatible with [RFC 3339](#). Log-level identifiers are also formatted as strings instead of numeric codes.

RFC 3339 timestamps are enabled by default for new PAS v2.2 deployments. Upgrades from earlier PAS versions retain the previous component log format with Unix epoch timestamps.

You can enable the new timestamp format for Diego logs in the PAS tile.

For more information, see the **Configure Application Containers** section of the [PAS installation topic for your IaaS](#).

 **Breaking Change:** Before enabling RFC 3339 format for Diego logs, ensure that your log aggregation system anticipates the timestamp format change. If you experience issues, you can disable RFC 3339 format in the PAS tile.

Task Placement More Resilient to Resource Unavailability

When memory or disk resources are temporarily unavailable, PAS no longer fails application and staging tasks immediately. Instead, it attempts several times to place the task on a Diego cell with sufficient capacity.

This temporary unavailability may occur when many application instances or tasks are being created or destroyed simultaneously or when the Diego Bulletin Board System (BBS) or auctioneer fails to communicate to one or more Diego cells.

For more information about Diego task allocation, see [How Diego Balances App Processes](#).

Instance Identity Certificates Contain CF Org and Space IDs

The instance identity certificates provided to application instance and task containers now contain organizational units with their CF org and space IDs in the certificate subject name. Existing applications must be restarted after an upgrade to PAS v2.2 to receive these new identifiers.

For more information, see [Using Instance Identity Credentials](#).

BOSH DNS Enabled By Default

BOSH DNS is enabled by default for both app containers and PCF components in PCF v2.2.

In previous versions, Consul managed service discovery between PCF components, but Consul is being replaced by BOSH DNS.

 **Note:** In PCF v2.2, Consul and BOSH DNS are both available in PCF, but BOSH DNS is the only service used for DNS requests.

You can disable BOSH DNS if instructed to do so by Pivotal support. If you disabled BOSH DNS in PCF v2.1, reenable it before upgrading to PCF v2.2. For more information, see [BOSH DNS Enabled By Default For App Containers and PCF Components](#).

 **warning:** Do not disable BOSH DNS without instructions from Pivotal support. Disabling BOSH DNS will also disable PKS, NSX-T, and several PAS features.

Service Discovery for Container-to-Container Networking Enabled By Default

In PAS v2.1, service discovery for container-to-container networking was an experimental feature that you could opt in to use. In PAS v2.2, this feature is enabled by default, and you can opt out of using it.

For more information about disabling service discovery for container-to-container networking, see the **Configure Application Developer Controls** section of the [PAS installation topic for your IaaS](#).

DNS Search Domains

PAS v2.2 allows you to configure the DNS search domains to be used in containers by entering a comma-separated list.

For more information, see the **DNS Search Domains** configuration described in the **Container Networking** section of the [PAS installation topic for your IaaS](#).

Pivotal Account Replaced by UAA

Prior to PAS v2.2, you could use Pivotal Account to create and manage user accounts. In PAS v2.2, PAS stops using Pivotal Account, and you can now create and manage user accounts through the UAA UI instead.

The **Errands** pane in the PAS tile replaces **Pivotal Account Errand** with the **Delete Pivotal Account Application** errand, which is configured to run automatically. For more information, see the **Configure Errands** section of the [PAS installation topic for your IaaS](#).

 **Note:** The **Delete Pivotal Account Application** errand does not delete the `account` database used by the app.

You can manually delete the `account` database that remains as an artifact in PAS MySQL by following these steps:

1. Use `bosh ssh` to access one of the MySQL VMs in your deployment. See [Advanced Troubleshooting with the BOSH CLI](#) for instructions. For example:

```
bosh ssh mysql/0
```

2. Run the following command to start MySQL using the credentials in `mylogin.cnf`:

```
mysql --defaults-file=/var/vcap/jobs/mysql/config/mylogin.cnf
```

3. Run the following command to delete the `account` database:

```
DROP database account;
```

Loggregator Adds Log Cache in PAS Advanced Features

Loggregator adds an in-memory caching layer for logs and metrics and provides a RESTful interface for retrieving them. Use Log Cache to query and filter

logs.

Log Cache is colocated on the Doppler VMs. It speeds up the retrieval of data from the Loggregator system, especially for deployments with a large number of Dopplers. Log Cache uses the available memory on a device to store logs, and so may impact performance during periods of high memory contention.

For more information about Log Cache, see [Enable Log Cache](#).

 **Breaking Change:** If you use Pivotal Application Service's App Autoscaler, Pivotal strongly recommends enabling Log Cache. App Autoscaler relies on Log Cache's API endpoints to function properly. If you disable Log Cache, App Autoscaler will fail.

 **Breaking Change:** Because of the addition of the log-cache process to the Doppler VM, the memory requirement for the Doppler VM has been increased to 4GB.

Syslog Draining for Service Instances (Beta)

The `cf-drain-cli` plugin now enables app developers to bind user-provided syslog drains to service instances. For more information, see the [CF Drain CLI Plugin](#)  GitHub repository. If a service tile supports syslog drains, app developers can use this plugin to forward logs and metrics from their service instance to an external endpoint.

Forwarding of DEBUG Syslog Messages Disabled by Default

By default, PAS v2.2 does not forward DEBUG syslog messages to external services. The new **Don't Forward Debug Logs** checkbox is configurable in the **System Logging** pane of the PAS tile.

For more information about configuring this checkbox, see the **(Optional) Configure System Logging** section of the [PAS installation topic for your IaaS](#) .

If you currently have a custom rule to filter out DEBUG syslog messages, you can delete it. Before deleting your custom rule, ensure the **Don't Forward Debug Logs** checkbox is enabled in the PAS tile.

App Autoscaler UI Integrated into Apps Manager

The App Autoscaler UI is now integrated into Apps Manager. This enables users to configure autoscaling for their apps through Apps Manager. The new UI is based on the App Autoscaler API v2.0.

For more information about scaling apps using App Autoscaler, see [Scaling an Application Using App Autoscaler](#).

Improved App Autoscaler CLI

The App Autoscaler CLI now supports creating custom autoscaling rules and scheduled limit changes for apps bound to the App Autoscaler service.

For more information about the App Autoscaler CLI, see [Using the App Autoscaler CLI](#).

Updated App Autoscaler Metrics Collection Interval Values

This release updates the minimum, maximum, and default values for the Metrics Collection Interval used by the App Autoscaler in PAS. Updated minimum: 60 seconds. Updated maximum: 3600 seconds. Updated default: 120 seconds.

To configure this value, see the **(Optional) Configure App Autoscaler** section of the [PAS installation topic for your IaaS](#) .

App Autoscaler Verbose Logging

Verbose logs are now available for App Autoscaler. Verbose logs show specific reasons why App Autoscaler scaled the app, information on minimum and maximum instance limits, App Autoscaler's status, and more. Verbose logs result in more detailed logs, but do not otherwise impact performance.

To enable verbose logs, select the **Verbose Logging** checkbox in the App Autoscaler pane.

For more information, see the **(Optional) Configure App Autoscaler** section of the [PAS installation topic for your IaaS](#).

Improved Session Management Behavior in Apps Manager

Users are now logged out of Apps Manager when they log out of UAA or their UAA session expires. You can configure the **Global Login Session Max Timeout** and **Global Login Session Idle Timeout** values in the **UAA** pane of the PAS tile.

Health Check Invocation Timeout is Configurable via Cloud Controller V3 API

This V3 API endpoint allows users to change the duration of a health check invocation timeout. An invocation timeout is a period of time within a standard timeout period, during which a healthcheck assess the health of your app. A responsive app is marked as alive, but an unresponsive app is marked as dead.

By default, the health check invocation timeout is set to one second. Increasing the invocation timeout period allows health checks to perform complex actions that may exceed the default timeout setting. A longer invocation timeout period may prevent your app from being marked as dead when it is actually healthy.

Change the invocation timeout period with the `invocation_timeout` flag in the healthcheck API.

For more information, see [The health_check object](#).

Selector-Based Subscription Model and Reference Nozzles

You can request Firehose subscriptions that filter out all unspecified content using the Loggregator v2 API endpoint from the Reverse Log Proxy.

For examples of nozzles that use the Loggregator V2 API and consume only specified whitelisted metrics, see `rlpreader` and `rlptypereader` in the [loggregator-tools](#) repository.

For more information about this feature, see the *V2 Subscriptions* page of the [loggregator-release](#) repository.

Known Issues

Downtime when Upgrading from v2.1 to v2.2.7 or Later

Upgrading directly from PAS v2.1.x to v2.2.7 or later may cause significant app downtime. If you are upgrading from v2.1.x, Pivotal recommends that you upgrade to v2.2.6 or an earlier patch release of v2.2.x. Once you are on v2.2.6 or an earlier patch release of v2.2.x, you can then upgrade to v2.2.7.

A fix for this issue is planned for v2.2.12.

For more information, see the following article in the Pivotal Knowledge Base: [How to avoid app downtime while upgrading from PAS v2.1.x to v2.2.7](#).

CredHub Database Cannot be External on GCP

If your PAS deployment is on GCP and you want to use Runtime CredHub, you must select **Internal** for both your system databases and CredHub database. If you are using external system databases, you cannot use CredHub.

CredHub is not compatible with the external database option on GCP. GCP Cloud SQL presents its certificate in a way that CredHub refuses to connect to it.

App Autoscaler Smoke Test Errand Failure

When deploying PAS v2.2.x, the App Autoscaler smoke test errand may fail with the following error:

Autoscaler did not receive any metrics for disk_quota during the scaling window. Scaling down will be deferred until these metrics are available.

For a workaround, see the following KB article: [App Autoscaler Smoke Test Errand fails to retrieve any metrics from logcache](#).

Apps Serve Routes After App Deletion Due to MySQL Errors

After an app is deleted, the app instances are not always cleaned up on Diego cells. Those instances continue to serve routes.

This error occurs when the Cloud Controller and Diego cells fall out of sync. You can resolve this issue by restarting the `cloud_controller_clock` process in the `clock_global` VM.

For more information, see the Knowledge Base article [Apps Serve Routes Even After App Deletion Due To MySQL Errors](#).

Timeouts Connecting to GCS Blobstores Using Service Account Key Authentication

Pushing large apps may fail if you use Google Cloud Storage (GCS) as an external blobstore, and you authenticate to it with a GCS Service Account. This option is configured in the PAS tile **File Storage** pane, under **Configure your Cloud Controller's filesystem**.

For more information, see the Knowledge Base article [Timeouts connecting to GCS blobstores when configured to use service account key authentication](#).

Deploying PAS Runtime for Windows Results in an Access is Denied Error

This rare issue can occur when you deploy the PAS Runtime for Windows v2.2.

The error reads:

```
Action Failed get_task: Task 5b085f4a-b56a-42e3-5974-f3876879397d result: Compiling package certspliter_windows: Removing packages: Uninstalling package bundle: remove /var/vcap/data/packages/golang-windows/83bf1f4181665d2ee2c0118a56bd04764b8f56b0/go/bin/go.exe: Access is denied.
```

If you encounter this error, Pivotal recommends retrying the deployment until the error does not occur.

For more information, see the Knowledge Base article [Deploying PAS for Windows Tile Results in an Access is Denied Error](#).

PAS Deployment Fails with Spring Cloud Services v1.5.5 and Earlier

If you are running Spring Cloud Services, you need to upgrade to Spring Cloud Services v1.5.6 or later before you can upgrade PCF to v2.2.

For more information, see the Knowledge Base article [Spring Cloud Services Deployment fails with can't resolve link error in PAS 2.2](#).

Some Components Use Go v1.9 to Avoid x.509 Cert Errors in v1.10

x509 certificate parsing in the Go language is [stricter in v1.10](#) than it is in v1.9. As a result, certificates that many Pivotal customers generated with open-source tools and continue to use could cause errors if parsed by Go v1.10. To avoid this, some PAS v2.2 components use Go v1.9. PAS v2.2 includes both versions of the language.

Configuring a List of TCP Routing Ports

This section describes an issue and workaround related to configuring a list of TCP Routing Ports in the PAS tile UI.

Issue

You cannot enter a comma-separated list of ports in the **TCP Routing Ports** field of the PAS tile. If you enter a comma-separated list, the Routing API does not start. The **TCP Routing Ports** field allows entries in the following formats:

- A single value, such as `1234`

- A range of values, such as `1234-5678`

Workaround

If you want to configure a list of ports, Pivotal recommends following these steps:

Note: This procedure causes brief downtime for TCP apps listening on ports that you open after deploying PAS.

1. Configure PAS with **Enable TCP Routing** selected.
2. Enter one port you want to use in the **TCP Routing Ports** field.
3. Deploy PAS.
4. Use the Routing API to add all desired TCP ports by following the instructions in the [Modify your TCP ports](#) section of the *Enabling TCP Routing* topic. When using the Routing API, you can include a comma separated list of ports.

Loggregator Component Horizontal Scaling Thresholds

Above approximately 40 Doppler instances and 25 Traffic Controller instances, horizontal scaling is no longer useful for improving Loggregator Firehose performance. To improve performance, increase CPU resources for the existing Doppler and Traffic Controller instances to add vertical scale.

The Syslog Adapter now enforces a hard limit on how many application syslog drains it can service, therefore it is important to follow the [scaling recommendations](#) to ensure that all syslog drains can be serviced.

Apps Manager SSL Validation Cannot Be Disabled in v2.2.12–v2.2.15

In v2.2.12–v2.2.15, Apps Manager ignores the **Disable SSL certificate verification for this environment** PAS tile setting. For environments using SSL certificates signed by an untrusted certificate authority (CA), this may cause Apps Manager to show no content.

To resolve this issue, see [Apps Manager shows no content due to SSL validation issue](#).

Apps Manager Only Allows One Intermediate Certificate Authority in v2.2.12–v2.2.14

In v2.2.12, v2.2.13, and v2.2.14, Apps Manager does not accept SSL certificates that have a signing chain with more than one intermediate certificate authority between the SSL certificate and the root certificate authority. This includes certificates from backend services such as the Cloud Controller API.

If there is more than one intermediate certificate authority, not counting the root certificate authority, the following happens:

- Apps Manager does not show content.
- The logs for Apps Manager include the text `certificate chain too long`.

If you must use an SSL certificate chain with more than one intermediate certificate authority in your environment, contact Pivotal Support to discuss options for working around this issue.

Cloud Controller Error Causes PCF Upgrade to Fail

With buildpacks now having stack associations, additional validation must be added while upgrading to PAS v2.2 and later. This can generate a new

`StacklessAndStackfulMatchingBuildpacksError` error in the post-start scripts.

For more information and instructions for fixing this error, see [Pivotal Cloud Foundry upgrade fails with a StacklessAndStackfulMatchingBuildpacksExistError Cloud Controller Error](#) in the Pivotal Knowledge Base.

PAS for Windows v2.2 Release Notes

This topic contains release notes for Pivotal Application Service (PAS) for Windows.

How to Upgrade

The PAS for Windows v2.2 tile is available with the release of Pivotal Cloud Foundry (PCF) v2.2. To use the PAS for Windows v2.2 tile, you must install Ops Manager v2.2 or later and PAS v2.2 or later.

Releases

2.2.9

- Bump windows2016 stemcell to version 1709.19
- Bump hwc-offline-buildpack to version 3.1.6
- Bump windows2016fs-release to version 2.2.0

| Component | Version |
|-----------------------|---------|
| windows2016 stemcell | 1709.19 |
| consul | 195 |
| diego | 2.8.7 |
| event-log | 0.7.0 |
| garden-runc | 1.16.8 |
| hwc-offline-buildpack | 3.1.6 |
| loggregator | 102.8 |
| winc | 1.8.0 |
| windows-utilities | 0.10.0 |
| windows2016fs-release | 2.2.0 |

2.2.8

- **[Feature]** Operators can provide trusted certs in OpsMgr for .NET apps to use automatically
- Bump hwc-offline-buildpack to version 3.1.5
- Bump winc to version 1.8.0

| Component | Version |
|-----------------------|---------|
| windows2016 stemcell | 1709.17 |
| consul | 195 |
| diego | 2.8.7 |
| event-log | 0.7.0 |
| garden-runc | 1.16.8 |
| hwc-offline-buildpack | 3.1.5 |
| loggregator | 102.8 |
| winc | 1.8.0 |
| windows-utilities | 0.10.0 |
| windows2016fs-release | 2.0.0 |

2.2.7

- Bump windows2016 stemcell to version 1709.17
- Bump diego to version 2.8.7
- Bump garden-runc to version 1.16.8
- Bump hwc-offline-buildpack to version 3.1.4
- Bump windows2016fs-release to version 2.0.0

| Component | Version |
|-----------------------|---------|
| windows2016 stemcell | 1709.17 |
| consul | 195 |
| diego | 2.8.7 |
| event-log | 0.7.0 |
| garden-runc | 1.16.8 |
| hwc-offline-buildpack | 3.1.4 |
| loggregator | 102.8 |
| winc | 1.7.0 |
| windows-utilities | 0.10.0 |
| windows2016fs-release | 2.0.0 |

2.2.6

- Bump windows2016 stemcell to version 1709.15
- Bump hwc-offline-buildpack to version 3.1.2
- Bump loggregator to version 102.8
- Bump windows2016fs-release to version 1.12.0

| Component | Version |
|-----------------------|---------|
| windows2016 stemcell | 1709.15 |
| consul | 195 |
| diego | 2.8.4 |
| event-log | 0.7.0 |
| garden-runc | 1.16.1 |
| hwc-offline-buildpack | 3.1.2 |
| loggregator | 102.8 |
| winc | 1.7.0 |
| windows-utilities | 0.10.0 |
| windows2016fs-release | 1.12.0 |

2.2.5

- [Security Fix] Rotate diego intermediate CA before current certificate expires
- [Feature Improvement] Operators can specify the Diego executor properties for memory usage and disk capacity in order to enable finer grained resource usage strategies.
- [Feature Improvement] Smoke tests for PASW are run as a post-deploy errand
- [Bug Fix] Fix issue that could cause application deployments to fail on some infrastructure due to incorrect MTU detection
- Bump to hwc-offline-buildpack compatible with PAS 2.2
- Bump windows2016 stemcell to version 1709.14
- Bump diego to version 2.8.4
- Bump hwc-offline-buildpack to version 3.1.1

- Bump winc to version `1.7.0`
- Bump windows2016fs-release to version `1.10.0`

| Component | Version |
|-----------------------|---------|
| windows2016 stemcell | 1709.14 |
| consul | 195 |
| diego | 2.8.4 |
| event-log | 0.7.0 |
| garden-runc | 1.16.1 |
| hwc-offline-buildpack | 3.1.1 |
| loggregator | 102.7 |
| winc | 1.7.0 |
| windows-utilities | 0.10.0 |
| windows2016fs-release | 1.10.0 |

2.2.4

- **[Security Fix]** Bump garden-runc to prevent malicious users from causing a denial of service for other apps
- **[Bug Fix]** Fix issue in loggregator where AZ names with special characters could cause metron agent job to fail
- Bump garden-runc to version `1.16.1`
- Bump hwc-offline-buildpack to version `3.0.2`
- Bump loggregator to version `102.7`
- Bump windows2016fs to version `1.8.0`
- Bump stemcell windows2016 to version `1709.13`

| Component | Version |
|-----------------------|---------|
| Stemcell | 1709.13 |
| consul | 195 |
| diego | 2.8.2 |
| event_log | 0.7.0 |
| garden-runc | 1.16.1 |
| hwc-offline-buildpack | 3.0.2 |
| loggregator | 102.7 |
| winc | 1.3.0 |
| windows2016fs | 1.8.0 |
| windows-utilities | 0.10.0 |

2.2.3

- Bump stemcell windows2016 version `1709.12`

| Component | Version |
|-----------------------|---------|
| Stemcell | 1709.12 |
| consul | 195 |
| diego | 2.8.2 |
| event_log | 0.7.0 |
| garden-runc | 1.13.3 |
| hwc-offline-buildpack | 2.3.19 |
| loggregator | 102.4 |
| | |

| Component | Version |
|-------------------|---------|
| winc | 1.3.0 |

New Features in PAS for Windows v2.2

New Format for Timestamps in Diego Component Logs

The timestamps in the Diego component logs are now in a format compatible with [RFC 3339](#). Log-level identifiers are also formatted as strings instead of numeric codes.

RFC 3339 timestamps are enabled by default for new v2.2 deployments. Upgrades from earlier versions retain the previous component log format with Unix epoch timestamps.

You can enable the new timestamp format for Diego logs in the PAS tile.

For more information, see the **Configure Application Containers** section of any IaaS-specific PAS configuration topic, such as [Deploying PAS on AWS](#).

 **Breaking Change:** Before enabling RFC 3339 format for Diego logs, ensure that your log aggregation system anticipates the timestamp format change. If you experience issues, you can disable RFC 3339 format in the PAS tile.

Known Issues

Deploying PAS Runtime for Windows Results in an Access is Denied Error

This rare issue can occur when you deploy the PAS Runtime for Windows v2.2.

The error reads:

```
Action Failed get_task: Task 5b085f4a-b56a-42e3-5974-f3876879397d result: Compiling package certsplitter_windows: Removing packages: Uninstalling package bundle: remove /var/vcap/data/packages/golang-windows/83bf1f4181665d2ee2c0118a56bd04764b8f56b0go\bin\go.exe: Access is denied.
```

If you encounter this error, Pivotal recommends retrying the deployment until the error does not occur.

For more information, see the Knowledge Base article [Deploying PAS for Windows Tile Results in an Access is Denied Error](#).

Consul Agent Job Does Not Prestart on Windows Diego Cells

In PAS for Windows v2.2, the `consul_agent_windows` job may fail to prestart when a Diego cell VM is created. The `Cannot index into a null array` error message typically indicates that your Diego cell VM is affected. To workaround this issue, you can recreate the VM.

PCF Isolation Segment v2.2 Release Notes

Known Issues

- **[Known Issue]** The NSX-T tile versions 2.3.1 and lower are not compatible with IST. Upcoming release NSX-T 2.3.2 will address this issue.

Releases

NOTE: BREAKING CHANGE You must upgrade to PAS 2.2.3 or greater prior to installing IST 2.2.4 or higher

2.2.15

- Bump ubuntu-trusty stemcell to version 3586.96
- Bump cflinuxfs2 to version 1.281.0

About PCF Isolation Segment

The PCF Isolation Segment v2.2 tile is available for installation with PCF v2.2.

[Isolation segments](#) provide dedicated pools of resources where you can deploy apps and isolate workloads. Using isolation segments separates app resources as completely as if they were in different CF deployments but avoids redundant management and network complexity.

For more information about using isolation segments in your deployment, see the [Managing Isolation Segments](#) topic.

How to Install

The procedure for installing PCF Isolation Segment v2.2 is documented in the [Installing PCF Isolation Segment](#) topic.

To install a PCF Isolation Segment, you must first install PCF v2.2.

New Features in PCF Isolation Segment v2.2

Gorouter Logging Changes for GDPR Compliance

Operators can now disable logging of client IP addresses in the Gorouter to comply with the General Data Protection Regulation (GDPR).

This setting, **Logging of Client IPs in CF Router**, is configured in the **Networking** pane of the PCF Isolation Segment tile. You can disable logging of the `X-Forwarded-For` HTTP header only or of both the source IP address and the `X-Forwarded-For` HTTP header. By default, the **Log client IPs** option is set in PCF Isolation Segment.

For more information about configuring the **Logging of Client IPs in CF Router** field, see [Networking](#) in the *Installing PCF Isolation Segment* topic.

New Format for Timestamps in Diego Component Logs

The timestamps in the Diego component logs are now in a format compatible with [RFC 3339](#). Log-level identifiers are also formatted as strings instead of numeric codes.

RFC 3339 timestamps are enabled by default for new v2.2 deployments. Upgrades from earlier versions retain the previous component log format with Unix epoch timestamps.

You can enable the new timestamp format for Diego logs in the Pivotal Application Service (PAS) tile.

For more information, see the **Configure Application Containers** section of any IaaS-specific PAS configuration topic, such as [Deploying PAS on AWS](#).

 **Breaking Change:** Before enabling RFC 3339 format for Diego logs, ensure that your log aggregation system anticipates the timestamp format change. If you experience issues, you can disable RFC 3339 format in the PAS tile.

DNS Search Domains

PCF Isolation Segment allows you to configure the DNS search domains used in containers by entering a comma-separated list.

For more information, see the **DNS Search Domains** configuration described in the **Container Networking** section of any IaaS-specific PAS configuration topic, such as [Deploying PAS on AWS](#).

Known issues

NSX-T v2.3.1 and Earlier Not Compatible with PCF Isolation Segment

The NSX-T tiles v2.3.1 and earlier are not compatible with PCF Isolation Segment. The Gorouters in an Isolation Segment are not given access in the firewall rules for NSX-T v2.3.1 and earlier, which prevents them from communicating with apps.

NSX-T v2.3.2 and later give access to the Gorouters in an Isolation Segment, and thus are compatible with PCF Isolation Segment.

About Advanced Features

The Advanced Features section of the PCF Isolation Segment v2.2 tile includes new functionality that may have certain constraints.

Although these features are fully supported, Pivotal recommends caution when using them in production.

Stemcell Release Notes

This topic provides an overview of the Stemcell versions used by Pivotal Cloud Foundry (PCF).

Stemcells are available for download on Pivotal Network. Once downloaded, you can upload them to your deployment using the **Stemcell** configuration pane of a given tile or by navigating to the **Stemcell Library** page in Ops Manager v2.1 or later.

Before you upgrade PCF, always verify that any tiles that you have installed, either from Pivotal or a partner, are compatible with the version of PCF you are deploying and its supported stemcells. For more information on checking PCF and stemcell compatibility, see [Tile Compatibility](#) in the Upgrade Checklist.

To find out which stemcell version is used by which tile version, check the release notes or the Pivotal Network download page for the tile.

 **Note:** A stemcell is a versioned OS image that BOSH uses to create VMs for the BOSH Director, Pivotal Application Service (PAS), and other PCF Service tiles, such as MySQL for PCF. For more information, see [What is a Stemcell?](#) in the BOSH documentation.

Ubuntu Linux Stemcell Lines

This section lists Linux-based stemcells used in Pivotal Cloud Foundry.

Trusty Stemcells

Each stemcell line has a corresponding release notes section. See the links below:

- [Stemcell 3586.x Release Notes](#)
- [Stemcell 3541.x Release Notes](#)
- [Stemcell 3468.x Release Notes](#)
- [Stemcell 3445.x Release Notes](#)
- [Stemcell 3421.x Release Notes](#)
- [Stemcell 3363.x Release Notes](#)

Trusty End-of-Support

Ubuntu 14.04 LTS (Trusty) stemcells are reaching end-of-support in April 2019. Starting in September 2018, Pivotal and its partners will begin releasing product tiles for PCF that support Ubuntu 16.04 LTS (Xenial) stemcells instead. Using supported stemcells is necessary to avoid exposure to security vulnerabilities.

Xenial Stemcells

Each stemcell line has a corresponding release notes section. See the links below:

- [Stemcell 97.x Release Notes](#)
- [Stemcell 87.x Release Notes](#)
- [Stemcell 81.x Release Notes](#)
- [Stemcell 60.x Release Notes](#)
- [Stemcell 50.x Release Notes](#)
- [Stemcell 40.x Release Notes](#)

Add-on Support for Xenial Stemcells

If you are using any of the following PCF add-ons, you must update the add-on and its configuration to be compatible with the Ubuntu Xenial 16.04 stemcell before deploying any tiles that use Xenial. The following add-on versions support the Xenial stemcell:

- ClamAV Add-on for PCF v1.2.22 or later. For information on how to update this add-on, see [Updating ClamAV Add-on for PCF to Run with Xenial Stemcells](#).
- File Integrity Monitoring (FIM) Add-on for PCF v1.4.28 or later. For information on how to update this add-on, see [Updating FIM Add-on for PCF to Run with Xenial Stemcells](#).
- IPSec Add-on for PCF v1.9.9 or later. For information on how to update this add-on, see [Updating IPSec Add-on for PCF to Run with Xenial Stemcells](#).

For information on which PCF tile releases now use Xenial, see [Tiles Using Xenial Stemcells in PCF](#).

Windows Stemcell Lines

This section lists Windows-based stemcells used in Pivotal Cloud Foundry. Each stemcell line has a corresponding release notes section. See the links below:

- [Stemcell 2019.x \(Windows Server version 2019\) Release Notes](#)
- [Stemcell 1803.x \(Windows Server version 1803\) Release Notes](#)
- [Stemcell 1709.x \(Windows Server version 1709\) Release Notes](#)
- [Stemcell 1200.x \(Windows2012R2\) Release Notes](#)

Stemcell (Linux) Release Notes

This topic includes release notes for Linux stemcells used with Pivotal Cloud Foundry (PCF).

Xenial Stemcells

The following sections describe each Xenial stemcell release.

315.x

This section includes release notes for the 315 line of Linux stemcells used with Pivotal Cloud Foundry (PCF).

315.41

✔ Available in Pivotal Network

Release Date: June 17, 2019

CVE fixes for <https://usn.ubuntu.com/4017-1/> [↗](#)

250.x

This section includes release notes for the 250 line of Linux stemcells used with Pivotal Cloud Foundry (PCF).

250.63

✔ Available in Pivotal Network

Release Date: June 17, 2019

CVE fixes for <https://usn.ubuntu.com/4017-1/> [↗](#)

250.56

✔ Available in Pivotal Network

Release Date: May 22, 2019

Release Date: March 21, 2019

Periodic stemcell bump (Mar 22, 2019)

250.21

✔ Available in Pivotal Network

Release Date: March 12, 2019

Periodic stemcell bump (Mar 15, 2019)

250.17

✔ Available in Pivotal Network

Release Date: February 25, 2019

Periodic stemcell bump (Mar 06, 2019)

250.9

Release Date: February 12, 2019

Periodic Ubuntu Xenial stemcell bump (Feb 13, 2019)

250.4

Release Date: January 29, 2019

First published xenial 250. stemcell.

170.x

This section includes release notes for the 170 line of Linux stemcells used with Pivotal Cloud Foundry (PCF).

170.82

✔ Available in Pivotal Network

Release Date: June 17, 2019

CVE fixes for <https://usn.ubuntu.com/4017-1/> [↗](#)

170.48

✔ Available in Pivotal Network

Release Date: April 08, 2019

Periodic stemcell bump (Apr 8, 2019)

170.45

✔ Available in Pivotal Network

Release Date: March 25, 2019

Periodic stemcell bump (Mar 26, 2019)

170.43

Release Date: March 21, 2019

Periodic stemcell bump (Mar 22, 2019)

170.39

✔ Available in Pivotal Network

Release Date: March 11, 2019

Periodic stemcell bump (Mar 15, 2019)

170.38

✔ Available in Pivotal Network

Release Date: February 25, 2019

Periodic stemcell bump (Mar 06, 2019)

170.30

✔ Available in Pivotal Network

Release Date: February 12, 2019

Periodic Ubuntu Xenial stemcell bump (Feb 12, 2019)

170.25

✔ Available in Pivotal Network

Release Date: January 28, 2019

Periodic Ubuntu Xenial stemcell bump (Jan 28, 2019)

170.24

✔ Available in Pivotal Network

Release Date: January 23, 2019

Addresses “USN-3866-1: Ghostscript vulnerability”

170.23

✔ Available in Pivotal Network

Release Date: January 22, 2019

Addresses “USN-3863-1: APT vulnerability”

170.21

Release Date: January 15, 2019

Periodic Ubuntu Xenial stemcell bump (Jan 15, 2019)

170.19

✔ Available in Pivotal Network

Release Date: January 11, 2019

Addresses “USN-3855-1: systemd vulnerabilities”

170.15

✔ Available in Pivotal Network

Release Date: December 20, 2018

Periodic Ubuntu Xenial stemcell bump (Dec 26, 2018)

170.14

✔ Available in Pivotal Network

Release Date: December 17, 2018

Periodic Ubuntu Xenial stemcell bump (Dec 17, 2018)

170.13

Release Date: December 11, 2018

Fixes

- *Google:* hostname should always be BOSH Agent ID ([#57](#), [#162225262](#))

170.12

Release Date: December 04, 2018

Periodic Ubuntu Xenial stemcell bump (Dec 05, 2018)

170.9

Release Date: November 19, 2018

Periodic Ubuntu Xenial stemcell bump (Nov 19, 2018)

170.6

Release Date: November 15, 2018

Includes updates to address:

- [USN-3820-2](#) [↗](#): Linux kernel (HWE) vulnerabilities

170.5

Release Date: November 05, 2018

Periodic Ubuntu Xenial stemcell bump (Nov 05, 2018)

97.x

This section includes release notes for the 97 line of Linux stemcells used with Pivotal Cloud Foundry (PCF).

97.113

✔ Available in Pivotal Network

Release Date: June 17, 2019

CVE fixes for <https://usn.ubuntu.com/4017-1/> [↗](#)

97.74

✔ Available in Pivotal Network

Release Date: April 08, 2019

Periodic stemcell bump (Apr 8, 2019)

97.71

✔ Available in Pivotal Network

Release Date: March 25, 2019

Periodic stemcell bump (Mar 26, 2019)

97.67

✔ Available in Pivotal Network

Release Date: March 15, 2019

Periodic stemcell bump (Mar 22, 2019)

97.66

✔ Available in Pivotal Network

Release Date: March 11, 2019

Periodic stemcell bump (Mar 15, 2019)

97.65

✔ Available in Pivotal Network

Release Date: February 25, 2019

Periodic stemcell bump (Mar 06, 2019)

97.57

✔ Available in Pivotal Network

Release Date: February 12, 2019

Periodic Ubuntu Xenial stemcell bump (Feb 13, 2019)

97.53

✔ Available in Pivotal Network

Release Date: January 28, 2019

Periodic Ubuntu Xenial stemcell bump (Jan 28, 2019)

97.52

✔ Available in Pivotal Network

Release Date: January 23, 2019

Addresses “USN-3866-1: Ghostscript vulnerability”

97.51

✔ Available in Pivotal Network

Release Date: January 22, 2019

Addresses “USN-3863-1: APT vulnerability”

97.49

Release Date: January 15, 2019

Periodic Ubuntu Xenial stemcell bump (Jan 15, 2019)

97.47

✔ Available in Pivotal Network

Release Date: January 11, 2019

Addresses “USN-3855-1: systemd vulnerabilities”

97.43

✔ Available in Pivotal Network

Release Date: December 20, 2018

Periodic Ubuntu Xenial stemcell bump (Dec 26, 2018)

97.42

✔ Available in Pivotal Network

Release Date: December 17, 2018

Periodic Ubuntu Xenial stemcell bump (Dec 17, 2018)

97.41

✔ Available in Pivotal Network

Release Date: December 11, 2018

- *Google*: hostname should always be BOSH Agent ID ([#57](#), [#162225262](#))
- Unpin rsyslog (was v8.22; backported from 170.x; [#162514665](#))
- Periodic Ubuntu Xenial updates

97.39

✔ Available in Pivotal Network

Release Date: December 04, 2018

Periodic Ubuntu Xenial stemcell bump (Dec 05, 2018)

97.34

✔ Available in Pivotal Network

Release Date: November 19, 2018

Periodic Ubuntu Xenial stemcell bump (Nov 19, 2018)

97.33

✔ Available in Pivotal Network

Release Date: November 15, 2018

Includes updates to address:

- [USN-3820-2](#): Linux kernel (HWE) vulnerabilities

97.32

✔ Available in Pivotal Network

Release Date: November 05, 2018

Periodic Ubuntu Xenial stemcell bump (Nov 08, 2018)

This stemcell addresses a bug introduced in the 97.31 release. The bug impacts AWS light stemcell users only.

97.31

✔ Available in Pivotal Network

Release Date: November 05, 2018

Do not use - this release has a bug that impacts the light stemcells Periodic Ubuntu Xenial stemcell bump (Nov 05, 2018)

97.22

Release Date: October 04, 2018

Addresses “USN-3777-2: Linux kernel (HWE) vulnerabilities” (Oct 04, 2018)

97.19

✔ Available in Pivotal Network

Release Date: October 02, 2018

(Oct 02, 2018)

97.18

✔ Available in Pivotal Network

Release Date: September 24, 2018

Periodic Ubuntu Xenial stemcell bump (Sep 25, 2018)

97.17

✔ Available in Pivotal Network

Release Date: September 18, 2018

Fixes mounting persistent disk issue with bosh-agent. (Sep 19, 2018)

97.16

✔ Available in Pivotal Network

Release Date: September 10, 2018

Periodic Ubuntu Xenial stemcell bump (Sep 11, 2018)

97.15

✔ Available in Pivotal Network

Release Date: August 27, 2018

Bump Ubuntu Xenial stemcells for “USN-3756-1: Intel Microcode vulnerabilities”

97.12

✔ Available in Pivotal Network

Release Date: August 14, 2018

Bump Ubuntu Xenial stemcells for “USN-3740-2: Linux kernel (HWE) vulnerabilities”

97.10

Release Date: August 13, 2018

Periodic Ubuntu Xenial stemcell bump (Aug 14, 2018)

97.5

Release Date: August 08, 2018

Bump Ubuntu Xenial stemcells for “USN-3732-2: Linux kernel (HWE) vulnerability”

97.3

Release Date: July 30, 2018

Periodic Ubuntu Xenial stemcell bump (July 31, 2018)

87.x

This section includes release notes for the 87 line of Linux stemcells used with Pivotal Cloud Foundry (PCF).

87.4

Release Date: July 16, 2018

Periodic Ubuntu Xenial stemcell bump (July 16, 2018)

87.3

Release Date: July 11, 2018

Periodic Ubuntu Xenial stemcell bump (July 12, 2018)

87

Release Date: July 02, 2018

Periodic Ubuntu Xenial stemcell bump (July 2, 2018)

81.x

This section includes release notes for the 81 line of Linux stemcells used with Pivotal Cloud Foundry (PCF).

81

Release Date: June 19, 2018

- Periodic Ubuntu Xenial stemcell bump (June 18, 2018)

60.x

This section includes release notes for the 60 line of Linux stemcells used with Pivotal Cloud Foundry (PCF).

60

Release Date: June 04, 2018

- Periodic Ubuntu Xenial stemcell bump (June 4, 2018)

50.x

This section includes release notes for the 50 line of Linux stemcells used with Pivotal Cloud Foundry (PCF).

50

Release Date: May 23, 2018

- Light stemcells are available

40.x

This section includes release notes for the 40 line of Linux stemcells used with Pivotal Cloud Foundry (PCF).

40

Release Date: May 22, 2018

- First release of Ubuntu Xenial stemcells
- Notable differences from Ubuntu Trusty
 - Includes systemd instead of upstart
 - Includes 4.15 Linux Kernel instead of 4.4
 - Uses chronyd to sync time (runs as a daemon) instead of ntpdate
 - Does not include NFS utils by default

Warning: Do not *downgrade* instances from Ubuntu Xenial to Ubuntu Trusty stemcells as it may corrupt persistent disk content since Trusty stemcells may decide to use sfdisk partitioner instead of parted partitioner selected by Xenial stemcells.

7.x

This section includes release notes for the 7 line of Linux stemcells used with Pivotal Cloud Foundry (PCF).

7

Release Date: June 03, 2019

Periodic stemcell bump (Jun 4, 2019)

7

Release Date: April 08, 2019

Periodic stemcell bump (Apr 8, 2019)

7

Release Date: February 14, 2019

Periodic CentOS 7 stemcell bump (Feb 14, 2019)

7

Release Date: January 28, 2019

Periodic CentOS 7 stemcell bump (Jan 28, 2019)

7

Release Date: January 16, 2019

Periodic CentOS 7 stemcell bump (Jan 17, 2019)

Trusty Stemcells

The following sections describe each Trusty stemcell release.

3763.x

This section includes release notes for the 3763 line of Linux stemcells used with Pivotal Cloud Foundry (PCF).

3763.14

Release Date: March 11, 2019

Periodic stemcell bump (Mar 14, 2019)

3763.13

Release Date: February 25, 2019

Periodic stemcell bump (Mar 08, 2019)

3586.x

This section includes release notes for the 3586 line of Linux stemcells used with Pivotal Cloud Foundry (PCF).

3586.93

Release Date: March 25, 2019

Periodic stemcell bump (Mar 26, 2019)

3586.91

Release Date: March 12, 2019

Periodic stemcell bump (Mar 15, 2019)

3586.86

Release Date: February 25, 2019

Periodic stemcell bump (Mar 06, 2019)

3586.79

Release Date: February 12, 2019

Periodic Ubuntu Trusty stemcell bump (Feb 14, 2019)

3586.71

Release Date: January 28, 2019

Periodic Ubuntu Trusty stemcell bump (Jan 28, 2019)

3586.70

Release Date: January 23, 2019

Addresses “USN-3866-1: Ghostscript vulnerability” and “USN-3863-1: APT vulnerability”

3586.67

Release Date: January 14, 2019

Periodic Ubuntu Trusty stemcell bump (Jan 15, 2019)

3586.65

Release Date: December 21, 2018

Periodic Ubuntu Trusty stemcell bump (Dec 21, 2018)

3586.63

Release Date: December 19, 2018

Periodic Ubuntu Trusty stemcell bump (Dec 19, 2018)

3586.60

Release Date: December 03, 2018

Periodic Ubuntu Trusty/CentOS stemcell bump (Dec 05, 2018)

3586.57

Release Date: November 19, 2018

Periodic Ubuntu Trusty/CentOS stemcell bump (Nov 19, 2018)

3586.56

Release Date: November 15, 2018

Periodic Ubuntu Trusty/CentOS stemcell bump (Nov 15, 2018)

3586.54

Release Date: November 05, 2018

Periodic Ubuntu Trusty/CentOS stemcell bump (Nov 05, 2018)

3586.52

Release Date: October 22, 2018

Periodic Ubuntu Trusty/CentOS stemcell bump (Oct 23, 2018)

3586.48

Release Date: October 08, 2018

Periodic Ubuntu Trusty/CentOS stemcell bump (Oct 11, 2018)

3586.46

Release Date: October 02, 2018

Addresses “USN-3776-2: Linux kernel (Xenial HWE) vulnerabilities” (Oct 02, 2018)

3586.43

Release Date: September 24, 2018

Periodic Ubuntu Trusty/CentOS stemcell bump (Sep 25, 2018)

3586.42

Release Date: September 10, 2018

Periodic Ubuntu Trusty/CentOS stemcell bump (Sep 11, 2018)

3586.40

Release Date: August 27, 2018

Bump Ubuntu Trusty stemcells for “USN-3756-1: Intel Microcode vulnerabilities”

Known Issue

- On GCP, writing moderate amounts of data to a persistent disk and then migrating the disk will fail with:

Error: Timed out sending 'update_settings'. See [#159511884](#) ↗

3586.36

Release Date: August 14, 2018

Bump Ubuntu Trusty stemcells for “USN-3741-2: Linux kernel (Xenial HWE) vulnerabilities”

3586.35

Release Date: August 13, 2018

Periodic Ubuntu Trusty/CentOS stemcell bump (Aug 14, 2018)

3586.27

Release Date: July 30, 2018

Periodic Ubuntu Trusty/CentOS stemcell bump (July 31, 2018)

3586.26

Release Date: July 16, 2018

Periodic Ubuntu Trusty stemcell bump (July 16, 2018)

3586.25

Release Date: July 02, 2018

- Periodic Ubuntu Trusty stemcell bump (July 2, 2018)

3586.24

Release Date: June 18, 2018

- Periodic Ubuntu Trusty stemcell bump (June 18, 2018)

3586.23

Release Date: June 13, 2018

- We are continuing to investigate GCP stemcell compatibility issue from earlier version, but we did roll back BOSH Agent to an earlier version that seems to not trigger this problem
 - Note: This build does not include fixes to recently published CVE-2018-3665

3586.18

Release Date: June 04, 2018

WARNING: We are currently investigating `unresponsive agent` issues when using the Google Cloud Platform version of this stemcell. In the meantime, please use `3586.16` when deploying to GCP.

- Periodic Ubuntu Trusty stemcell bump (June 4, 2018)

3586.16

Release Date: May 24, 2018

- Bump Ubuntu Trusty stemcells for “USN-3654-2: Linux kernel (Xenial HWE) vulnerabilities”

TLS for Internal Blobstore Supported

For Ops Manager v2.2 and later, you can enable TLS for your internal blobstore. Make sure you configured all tiles with a stemcell v3586 or later before enabling TLS for your internal blobstore.

For more information, see [TLS for Internal Blobstore Supported](#) in the Ops Manager release notes.

3586.8

Release Date: May 21, 2018

- Periodic Ubuntu Trusty stemcell bump (May 21, 2018)

3586.7

Release Date: May 09, 2018

- Bump Ubuntu Trusty stemcells for “USN-3641-1: Linux kernel vulnerabilities”

3586.5

Release Date: May 08, 2018

- Bump s3cli to include AliCloud support
- Bump bosh-agent
 - Support network aliases (used by Softlayer CPI)
 - Support static routes for networks (used by Softlayer CPI)
 - Support iSCSI for persistent disks (used by Softlayer CPI)
 - Use parted when GPT partitions are detected
 - Refactor retryable strategy usages

3541.x

This section includes release notes for the 3541 line of Linux stemcells used with Pivotal Cloud Foundry (PCF).

3541.65

Release Date: December 07, 2018

Periodic Ubuntu Trusty/CentOS stemcell bump (Dec 07, 2018)

3541.64

Release Date: December 03, 2018

Periodic Ubuntu Trusty/CentOS stemcell bump (Dec 05, 2018)

3541.61

Release Date: November 19, 2018

Periodic Ubuntu Trusty/CentOS stemcell bump (Nov 19, 2018)

3541.60

Release Date: November 15, 2018

Periodic Ubuntu Trusty/CentOS stemcell bump (Nov 15, 2018)

3541.57

Release Date: October 22, 2018

Periodic Ubuntu Trusty/CentOS stemcell bump (Oct 23, 2018)

3541.54

Release Date: October 08, 2018

Periodic Ubuntu Trusty/CentOS stemcell bump (Oct 11, 2018)

3541.52

Release Date: October 02, 2018

Addresses “USN-3776-2: Linux kernel (Xenial HWE) vulnerabilities” (Oct 02, 2018)

3541.49

Release Date: September 24, 2018

Periodic Ubuntu Trusty/CentOS stemcell bump (Sep 25, 2018)

3541.48

Release Date: September 10, 2018

Periodic Ubuntu Trusty/CentOS stemcell bump (Sep 11, 2018)

3541.46

Release Date: August 27, 2018

Bump Ubuntu Trusty stemcells for “USN-3756-1: Intel Microcode vulnerabilities”

3541.44

Release Date: August 14, 2018

Bump Ubuntu Trusty stemcells for “USN-3741-2: Linux kernel (Xenial HWE) vulnerabilities”

3541.43

Release Date: August 13, 2018

Periodic Ubuntu Trusty/CentOS stemcell bump (Aug 14, 2018)

3541.37

Release Date: July 30, 2018

Periodic Ubuntu Trusty stemcell bump (July 31, 2018)

3541.36

Release Date: July 16, 2018

Periodic Ubuntu Trusty stemcell bump (July 16, 2018)

3541.35

Release Date: July 02, 2018

- Periodic Ubuntu Trusty stemcell bump (July 2, 2018)

3541.34

Release Date: June 18, 2018

- Periodic Ubuntu Trusty stemcell bump (June 18, 2018)

3541.31

Release Date: June 04, 2018

- Periodic Ubuntu Trusty stemcell bump (June 4, 2018)

3541.25

Release Date: May 09, 2018

- Bump Ubuntu Trusty stemcells for “USN-3641-1: Linux kernel vulnerabilities”

3541.30

Release Date: May 23, 2018

- Bump Ubuntu Trusty stemcells for “USN-3654-2: Linux kernel (Xenial HWE) vulnerabilities”

3541.26

Release Date: May 21, 2018

- Periodic Ubuntu Trusty stemcell bump (May 21, 2018)

3541.24

Release Date: May 07, 2018

- Ubuntu Trusty stemcells periodic update (May 7, 2018)

3541.12

Release Date: April 06, 2018

- Bump Ubuntu Trusty stemcells for USN-3619-2: Linux kernel (Xenial HWE) vulnerabilities

3541.10

Release Date: March 26, 2018

- Periodic Ubuntu and CentOS stemcell bump (March 26/27, 2018)

3541.9

Release Date: March 12, 2018

- Periodic Ubuntu and CentOS stemcell bump (March 12, 2018)

3541.8

Release Date: March 08, 2018

- Bump bosh-agent to 2.67.1
 - Agent will now respect previously set permissions and owner on `sys/run`, `sys/log` and data job directories
 - This should fix stemcell compatibility with Diego/Garden if Agent restarts
 - If you were using 3541.x stemcell for any of your deployments, it's recommended to update your deployments to this version before updating Director since that would cause Agent restart

3541.5

Release Date: February 22, 2018

- Bump Ubuntu Trusty stemcells for USN-3582-2: Linux kernel (Xenial HWE) vulnerabilities

3541.4

Release Date: February 14, 2018

- Rolled back custom umask configuration as we found out it was different in some cases (depends on how processes were started)
 - Hardening of `/var/vcap/jobs/*` is still applied by the agent

3541.2

Release Date: February 08, 2018

- [breaking] Set default umask to 077 and further harden several `/var/vcap/*` directories
 - Note that you may have to change your release to adapt to this change
- [breaking] Renamed `/var/vcap/bosh/bin/ntpdate` to `/var/vcap/bosh/bin/sync-time`
- [breaking] Stop forwarding SSH events to bosh-agent
 - Agent no longer receives and forwards such events to HM. This should remove a lot of noisy generated by releases that expect a lot of SSH sessions (eg Gitlab). This information will continue to be available in logs forwarded to remote destinations (and locally `/var/log/auth.log`).
- Fixes `env.bosh.swap_size: 0` to work on more clouds (including GCP)

Misc

- Order stemcell tarballs so that upload-stemcell command can execute faster
- Generate `packages.txt` within stemcell tarball that includes list of installed packages (previously known under different name)

3469.x

This section includes release notes for the 3469 line of Linux stemcells used with Pivotal Cloud Foundry (PCF).

3469.1

Release Date: February 27, 2018

- Stemcell produced for testing rsyslog bump to the latest version
 - Unless testing rsyslog, use 3468.x or 3541.x stemcell lines

3468.x

This section includes release notes for the 3468 line of Linux stemcells used with Pivotal Cloud Foundry (PCF).

3468.78

Release Date: October 22, 2018

Periodic Ubuntu Trusty stemcell bump (Oct 23, 2018)

3468.75

Release Date: October 08, 2018

Periodic Ubuntu Trusty stemcell bump (Oct 11, 2018)

3468.73

Release Date: October 02, 2018

Addresses “USN-3776-2: Linux kernel (Xenial HWE) vulnerabilities” (Oct 02, 2018)

3468.71

Release Date: September 24, 2018

Periodic Ubuntu Trusty stemcell bump (Sep 25, 2018)

3468.69

Release Date: September 10, 2018

Periodic Ubuntu Trusty stemcell bump (Sep 11, 2018)

3468.67

Release Date: August 27, 2018

Bump Ubuntu Trusty stemcells for “USN-3756-1: Intel Microcode vulnerabilities”

3468.64

Release Date: August 14, 2018

Bump Ubuntu Trusty stemcells for “USN-3741-2: Linux kernel (Xenial HWE) vulnerabilities”

3468.63

Release Date: August 13, 2018

Periodic Ubuntu Trusty stemcell bump (Aug 14, 2018)

3468.55

Release Date: July 30, 2018

Periodic Ubuntu Trusty stemcell bump (July 31, 2018)

3468.54

Release Date: July 16, 2018

Periodic Ubuntu Trusty stemcell bump (July 16, 2018)

3468.53

Release Date: July 02, 2018

- Periodic Ubuntu Trusty stemcell bump (July 2, 2018)

3468.51

Release Date: June 18, 2018

- Periodic Ubuntu Trusty stemcell bump (June 18, 2018)

3468.47

Release Date: June 04, 2018

- Periodic Ubuntu Trusty stemcell bump (June 4, 2018)

3468.42

Release Date: May 09, 2018

- Bump Ubuntu Trusty stemcells for “USN-3641-1: Linux kernel vulnerabilities”

3468.46

Release Date: May 23, 2018

- Bump Ubuntu Trusty stemcells for “USN-3654-2: Linux kernel (Xenial HWE) vulnerabilities”

3468.44

Release Date: May 21, 2018

- Periodic Ubuntu Trusty stemcell bump (May 21, 2018)

3468.41

Release Date: May 07, 2018

- Ubuntu Trusty stemcells periodic update (May 7, 2018)

3468.30

Release Date: April 06, 2018

- Bump Ubuntu Trusty stemcells for USN-3619-2: Linux kernel (Xenial HWE) vulnerabilities

3468.28

Release Date: March 26, 2018

- Periodic Ubuntu and CentOS stemcell bump (March 26/27, 2018)

3468.27

Release Date: March 12, 2018

- Periodic Ubuntu and CentOS stemcell bump (March 12, 2018)

3468.26

Release Date: March 01, 2018

- Includes updated `ixgbevf 4.3.4`

3468.25

Release Date: February 22, 2018

- Bump Ubuntu Trusty stemcells for USN-3582-2: Linux kernel (Xenial HWE) vulnerabilities

3468.22

Release Date: February 05, 2018

- [Feb 5] Periodic stemcell bump

3468.21

Release Date: January 23, 2018

- No functional change from 3468.20, except version number

3468.20

Release Date: January 23, 2018

- Bump Ubuntu Trusty stemcells for [USN-3540-2: Linux kernel \(Xenial HWE\) vulnerabilities](#) [↗](#) (This flaw is known as Spectre.)

3468.19

Release Date: January 17, 2018

- Bump Ubuntu Trusty stemcells for USN-3534-1: GNU C Library vulnerabilities

3468.17

Release Date: January 10, 2018

- Bump Ubuntu Trusty stemcells for [USN-3522-4: Linux kernel \(Xenial HWE\) regression](#) [↗](#)
- Configure vSphere stemcells to use VM hardware version 9 (requires ESXi 5.1) to be compatible with <https://www.vmware.com/us/security/advisories/VMSA-2018-0004.html> [↗](#)

3468.16

Release Date: January 10, 2018

- Bump Ubuntu Trusty stemcells for [USN-3522-2: Linux \(Xenial HWE\) vulnerability](#) [↗](#) (This flaw is known as Meltdown.)

3468.15

Release Date: December 15, 2017

- Bump Ubuntu Trusty stemcells for USN-3509-4: Linux kernel (Xenial HWE) regression

3468.13

Release Date: December 08, 2017

- Bump Ubuntu Trusty stemcell USN-3509-2: Linux kernel (Xenial HWE) vulnerabilities

3468.12

Release Date: December 06, 2017

- Bump Ubuntu Trusty stemcells for USN-3505-1: Linux firmware vulnerabilities

3468.11

Release Date: November 21, 2017

- Periodic Ubuntu stemcells update
- Includes Agent changes to support IPv6 on vSphere (manual networking)

3468.5

Release Date: October 26, 2017

- Configure `/tmp` to have sticky bit set

3468.1

Release Date: October 23, 2017

- Periodic stemcell bump

3468

Release Date: October 05, 2017

- Removed password authentication for Warden stemcells
- Various minor tweaks that were already backported to older lines

Upcoming features on this stemcell line:

- IPv6 support for vSphere

3445.x

This section includes release notes for the 3445 line of Linux stemcells used with Pivotal Cloud Foundry (PCF).

3445.76

Release Date: October 22, 2018

Periodic Ubuntu Trusty stemcell bump (Oct 23, 2018)

3445.73

Release Date: October 08, 2018

Periodic Ubuntu Trusty stemcell bump (Oct 11, 2018)

3445.71

Release Date: October 02, 2018

Addresses “USN-3776-2: Linux kernel (Xenial HWE) vulnerabilities” (Oct 02, 2018)

3445.68

Release Date: September 24, 2018

Periodic Ubuntu Trusty stemcell bump (Sep 25, 2018)

3445.67

Release Date: September 10, 2018

Periodic Ubuntu Trusty stemcell bump (Sep 10, 2018)

3445.66

Release Date: August 27, 2018

Bump Ubuntu Trusty stemcells for “USN-3756-1: Intel Microcode vulnerabilities”

3445.64

Release Date: August 14, 2018

Bump Ubuntu Trusty stemcells for “USN-3741-2: Linux kernel (Xenial HWE) vulnerabilities”

3445.63

Release Date: August 13, 2018

Periodic Ubuntu Trusty stemcell bump (Aug 14, 2018)

3445.55

Release Date: July 30, 2018

Periodic Ubuntu Trusty stemcell bump (July 31, 2018)

3445.54

Release Date: July 16, 2018

Periodic Ubuntu Trusty stemcell bump (July 16, 2018)

3445.53

Release Date: July 02, 2018

- Periodic Ubuntu Trusty stemcell bump (July 2, 2018)

3445.51

Release Date: June 18, 2018

- Periodic Ubuntu Trusty stemcell bump (June 18, 2018)

3445.49

Release Date: June 04, 2018

- Periodic Ubuntu Trusty stemcell bump (June 4, 2018)

3445.48

Release Date: May 23, 2018

- Bump Ubuntu Trusty stemcells for “USN-3654-2: Linux kernel (Xenial HWE) vulnerabilities”

3445.42

Release Date: May 01, 2018

- Ubuntu Trusty stemcells periodic update (Apr 30, 2018)

3445.46

Release Date: May 21, 2018

- Periodic Ubuntu Trusty stemcell bump (May 21, 2018)

3445.45

Release Date: May 09, 2018

- Bump Ubuntu Trusty stemcells for “USN-3641-1: Linux kernel vulnerabilities”

3445.44

Release Date: May 07, 2018

- Ubuntu Trusty stemcells periodic update (May 7, 2018)

3445.32

Release Date: April 06, 2018

- Bump Ubuntu Trusty stemcells for USN-3619-2: Linux kernel (Xenial HWE) vulnerabilities

3445.30

Release Date: March 26, 2018

- Periodic Ubuntu Trusty stemcell bump (March 26/27, 2018)

3445.29

Release Date: March 12, 2018

- Periodic Ubuntu Trusty stemcell bump (March 12, 2018)

3445.28

Release Date: February 22, 2018

- Bump Ubuntu Trusty stemcells for USN-3582-2: Linux kernel (Xenial HWE) vulnerabilities

3445.25

Release Date: February 05, 2018

- [Feb 5] Periodic stemcell bump

3445.24

Release Date: January 23, 2018

- Bump Ubuntu Trusty stemcells for [USN-3540-2: Linux kernel \(Xenial HWE\) vulnerabilities](#) [↗](#) (This flaw is known as Spectre.)

3445.23

Release Date: January 17, 2018

- Bump Ubuntu Trusty stemcells for USN-3534-1: GNU C Library vulnerabilities

3445.22

Release Date: January 10, 2018

- Bump Ubuntu Trusty stemcells for [USN-3522-4: Linux kernel \(Xenial HWE\) regression](#) [↗](#)
- Configure vSphere stemcells to use VM hardware version 9 (requires ESXi 5.1) to be compatible with <https://www.vmware.com/us/security/advisories/VMSA-2018-0004.html> [↗](#)

3445.21

Release Date: January 10, 2018

- Bump Ubuntu Trusty stemcells for [USN-3522-2: Linux \(Xenial HWE\) vulnerability](#) [↗](#) (This flaw is known as Meltdown.)

3445.19

Release Date: December 08, 2017

- Bump Ubuntu Trusty stemcell USN-3509-2: Linux kernel (Xenial HWE) vulnerabilities

3445.18

Release Date: December 06, 2017

- Bump Ubuntu Trusty stemcells for USN-3505-1: Linux firmware vulnerabilities

3445.17

Release Date: November 21, 2017

- Periodic Ubuntu stemcells update

3445.11

Release Date: September 19, 2017

- Bump Ubuntu stemcells for USN-3420-2: Linux kernel (Xenial HWE) vulnerabilities

3445.7

Release Date: August 30, 2017

- Logrotate /var/log/wtmp and utmp more aggressively
- Updated BOSH agent to include aggressive 5 minute timeout on NATS connection failure
- Set auditd rules to be mutable by default
 - Please use `auditd` job from os-conf-release to make rules immutable

3445.2

Release Date: August 16, 2017

- Bump Ubuntu stemcells for [USN-3392-2: Linux kernel \(Xenial HWE\) regression](#) [↗](#)

3445

Release Date: August 11, 2017

- Bump Ubuntu stemcells for [USN-3385-2: Linux kernel \(Xenial HWE\) vulnerabilities](#) [↗](#)
- Include gcscli for native GCS support
- Bump bosh-agent to include support for colocated errand jobs
- Fix occasional rsyslog hang on startup (as a workaround for <https://github.com/rsyslog/rsyslog/issues/1188> [↗](#))

3431.x

This section includes release notes for the 3431 line of Linux stemcells used with Pivotal Cloud Foundry (PCF).

3431.13

Release Date: August 03, 2017

- Bump version (no change)

3431.11

Release Date: August 03, 2017

- Bump Ubuntu Trusty stemcells for [USN-3378-2: Linux kernel \(Xenial HWE\) vulnerabilities](#) [↗](#)
- Fix occasional rsyslog hang on startup
 - Workaround for <https://github.com/rsyslog/rsyslog/issues/1188> [↗](#)

3431.10

Release Date: July 31, 2017

- Periodic Ubuntu stemcells update

3422.x

This section includes release notes for the 3422 line of Linux stemcells used with Pivotal Cloud Foundry (PCF).

3422.7

Release Date: November 22, 2017

- Test stemcell for umask changes (based on 3468.x stemcell line)

3421.x

This section includes release notes for the 3421 line of Linux stemcells used with Pivotal Cloud Foundry (PCF).

3421.88

Release Date: October 08, 2018

Periodic Ubuntu Trusty stemcell bump (Oct 11, 2018)

3421.86

Release Date: October 02, 2018

Addresses “USN-3776-2: Linux kernel (Xenial HWE) vulnerabilities” (Oct 02, 2018)

3421.83

Release Date: September 24, 2018

Periodic Ubuntu Trusty stemcell bump (Sep 25, 2018)

3421.82

Release Date: September 10, 2018

Periodic Ubuntu Trusty stemcell bump (Sep 10, 2018)

3421.81

Release Date: August 27, 2018

Bump Ubuntu Trusty stemcells for “USN-3756-1: Intel Microcode vulnerabilities”

3421.79

Release Date: August 14, 2018

Bump Ubuntu Trusty stemcells for “USN-3741-2: Linux kernel (Xenial HWE) vulnerabilities”

3421.78

Release Date: August 13, 2018

Periodic Ubuntu Trusty stemcell bump (Aug 14, 2018)

3421.70

Release Date: July 30, 2018

Periodic Ubuntu Trusty stemcell bump (July 31, 2018)

3421.69

Release Date: July 16, 2018

Periodic Ubuntu Trusty stemcell bump (July 16, 2018)

3421.68

Release Date: July 02, 2018

- Periodic Ubuntu Trusty stemcell bump (July 2, 2018)

3421.66

Release Date: June 18, 2018

- Periodic Ubuntu Trusty stemcell bump (June 18, 2018)

3421.64

Release Date: June 04, 2018

- Periodic Ubuntu Trusty stemcell bump (June 4, 2018)

3421.63

Release Date: May 23, 2018

- Bump Ubuntu Trusty stemcells for “USN-3654-2: Linux kernel (Xenial HWE) vulnerabilities”

3421.56

Release Date: May 01, 2018

- Ubuntu Trusty stemcells periodic update (Apr 30, 2018)

3421.60

Release Date: May 21, 2018

- Periodic Ubuntu Trusty stemcell bump (May 21, 2018)

3421.59

Release Date: May 09, 2018

- Bump Ubuntu Trusty stemcells for “USN-3641-1: Linux kernel vulnerabilities”

3421.58

Release Date: May 07, 2018

- Ubuntu Trusty stemcells periodic update (May 7, 2018)

3421.46

Release Date: April 06, 2018

- Bump Ubuntu Trusty stemcells for USN-3619-2: Linux kernel (Xenial HWE) vulnerabilities

3421.44

Release Date: March 26, 2018

- Periodic Ubuntu Trusty stemcell bump (March 26/27, 2018)

3421.43

Release Date: March 12, 2018

- Periodic Ubuntu Trusty stemcell bump (March 12, 2018)

3421.42

Release Date: February 22, 2018

- Bump Ubuntu Trusty stemcells for USN-3582-2: Linux kernel (Xenial HWE) vulnerabilities

3421.39

Release Date: February 05, 2018

- [Feb 5] Periodic stemcell bump

3421.38

Release Date: January 23, 2018

- Bump Ubuntu Trusty stemcells for [USN-3540-2: Linux kernel \(Xenial HWE\) vulnerabilities](#) [↗](#) (This flaw is known as Spectre.)

3421.37

Release Date: January 17, 2018

- Bump Ubuntu Trusty stemcells for USN-3534-1: GNU C Library vulnerabilities

3421.36

Release Date: January 10, 2018

- Bump Ubuntu Trusty stemcells for [USN-3522-4: Linux kernel \(Xenial HWE\) regression](#) [↗](#)
- Configure vSphere stemcells to use VM hardware version 9 (requires ESXi 5.1) to be compatible with <https://www.vmware.com/us/security/advisories/VMSA-2018-0004.html> [↗](#)

3421.35

Release Date: January 10, 2018

- Bump Ubuntu Trusty stemcells for [USN-3522-2: Linux \(Xenial HWE\) vulnerability](#) [↗](#) (This flaw is known as Meltdown.)

3421.34

Release Date: December 08, 2017

- Bump Ubuntu Trusty stemcell USN-3509-2: Linux kernel (Xenial HWE) vulnerabilities

3421.33

Release Date: December 06, 2017

- Bump Ubuntu Trusty stemcells for USN-3505-1: Linux firmware vulnerabilities

3421.32

Release Date: November 21, 2017

- Periodic Ubuntu stemcells update

3421.20

Release Date: August 16, 2017

- Bump Ubuntu stemcells for [USN-3392-2: Linux kernel \(Xenial HWE\) regression](#) [↗](#)

3421.19

Release Date: August 11, 2017

- Bump Ubuntu stemcells for [USN-3385-2: Linux kernel \(Xenial HWE\) vulnerabilities](#) [↗](#)

3421.18

Release Date: August 03, 2017

- Bump Ubuntu Trusty stemcells for [USN-3378-2: Linux kernel \(Xenial HWE\) vulnerabilities](#) [↗](#)
- Fix occasional rsyslog hang on startup
 - Workaround for <https://github.com/rsyslog/rsyslog/issues/1188> [↗](#)

3421.11

Release Date: June 29, 2017

- Bump Ubuntu stemcells for USN-3344-2: Linux kernel (Xenial HWE) vulnerabilities

3421.9

Release Date: June 21, 2017

- Bump Ubuntu stemcells for USN-3334-1: Linux kernel (Xenial HWE) vulnerabilities

3421.6

Release Date: June 09, 2017

- Bump Ubuntu stemcells for USN-3312-2 - Linux kernel vulnerabilities

3421.4

Release Date: June 01, 2017

- Bump CentOS stemcells for CESA-2017:1382 - sudo vulnerability

3421.3

Release Date: May 30, 2017

- Bump Ubuntu stemcells for USN-3304-1: Sudo vulnerability

3421

Release Date: May 22, 2017

New:

- Added `env.bosh.remove_static_libraries` (bool) to remove static libraries
 - Useful to enable this option when exporting compiled releases
- Added `env.bosh.ipv6.enable` (bool) to remove ipv6.disable kernel functionality at bootup time

Fixes:

- Fixed sysstat logging
- Fixed anacron's RANDOM_DELAY configuration

Bumps:

- Bumped s3cli v0.0.60
 - Updated aws-sdk-go to solve network timeout edge case
- Bumped davcli v0.0.19
 - Use TCP keep alive to solve network timeout edge case
- Bumped bosh-agent v0.0.35
 - Add `-v` to the Agent binary
 - Prepared `sync_dns` action to work with future Director's DNS integration

3363.x

This section includes release notes for the 3363 line of Linux stemcells used with Pivotal Cloud Foundry (PCF).

3363.65

Release Date: June 18, 2018

- Periodic Ubuntu Trusty stemcell bump (July 18, 2018)

3363.64

Release Date: June 04, 2018

- Periodic Ubuntu Trusty stemcell bump (June 4, 2018)

3363.63

Release Date: May 23, 2018

- Bump Ubuntu Trusty stemcells for “USN-3654-2: Linux kernel (Xenial HWE) vulnerabilities”

3363.62

Release Date: May 21, 2018

- Periodic Ubuntu Trusty stemcell bump (May 21, 2018)

3363.61

Release Date: May 09, 2018

- Bump Ubuntu Trusty stemcells for “USN-3641-1: Linux kernel vulnerabilities”

3363.60

Release Date: May 07, 2018

- Ubuntu Trusty stemcells periodic update (May 7, 2018)

3363.53

Release Date: April 06, 2018

- Bump Ubuntu Trusty stemcells for USN-3619-2: Linux kernel (Xenial HWE) vulnerabilities

3363.52

Release Date: March 26, 2018

- Periodic Ubuntu Trusty stemcell bump (March 26/27, 2018)

3363.51

Release Date: March 12, 2018

- Periodic Ubuntu Trusty stemcell bump (March 12, 2018)

3363.50

Release Date: February 22, 2018

- Bump Ubuntu Trusty stemcells for USN-3582-2: Linux kernel (Xenial HWE) vulnerabilities

3363.49

Release Date: February 05, 2018

- [Feb 5] Periodic stemcell bump

3363.48

Release Date: January 23, 2018

- Bump Ubuntu Trusty stemcells for [USN-3540-2: Linux kernel \(Xenial HWE\) vulnerabilities](#) [↗](#) (This flaw is known as Spectre.)

3363.47

Release Date: January 17, 2018

- Bump Ubuntu Trusty stemcells for USN-3534-1: GNU C Library vulnerabilities

3363.46

Release Date: January 10, 2018

- Bump Ubuntu Trusty stemcells for [USN-3522-4: Linux kernel \(Xenial HWE\) regression](#) [↗](#)
- Configure vSphere stemcells to use VM hardware version 9 (requires ESXi 5.1) to be compatible with <https://www.vmware.com/us/security/advisories/VMSA-2018-0004.html> [↗](#)

3363.45

Release Date: January 10, 2018

- Bump Ubuntu Trusty stemcells for [USN-3522-2: Linux \(Xenial HWE\) vulnerability](#) [↗](#) (This flaw is known as Meltdown.)

3363.44

Release Date: December 08, 2017

- Bump Ubuntu Trusty stemcell USN-3509-2: Linux kernel (Xenial HWE) vulnerabilities

3363.43

Release Date: December 06, 2017

- Bump Ubuntu Trusty stemcells for USN-3505-1: Linux firmware vulnerabilities

3363.42

Release Date: November 21, 2017

- Periodic Ubuntu stemcells update

3363.24

Release Date: May 17, 2017

- Periodic Ubuntu stemcells update

3363.22

Release Date: May 11, 2017

- Periodic Ubuntu stemcells update
- Run `cron` in BOSH Lite stemcells so that logrotation is performed

3363.20

Release Date: April 25, 2017

- Bump Ubuntu stemcells for USN-3265-2: Linux kernel (Xenial HWE) vulnerabilities

3363.19

Release Date: April 17, 2017

- Periodic bump for CentOS stemcells to include CESA-2017:0933
- Disable IPv6 through `/proc/cmdline` to eliminate possibility of listening on tcp6/udp6

3363.15

Release Date: April 05, 2017

- Bump Ubuntu stemcells for USN-3256-2: Linux kernel (HWE) vulnerability

Misc:

- Made AWS AMI backing snapshot public to support encryption of boot disks

3363.14

Release Date: March 30, 2017

- Bump Ubuntu stemcells for USN-3249-2: Linux kernel (Xenial HWE) vulnerability

3363.10

Release Date: March 08, 2017

- Bumps Ubuntu stemcells for USN-3220-2: Linux kernel (Xenial HWE) vulnerability

3363.9

Release Date: February 22, 2017

Changes: - Bumps Ubuntu stemcells for USN-3208-2: Linux kernel (Xenial HWE) vulnerabilities - Fixes excessive “out of memory” errors in kernel - <https://bugs.launchpad.net/ubuntu/+source/linux/+bug/1655842> - Fixes regression to rsyslog by locking it down again to rsyslog 8.22.0

Agent: - Fixes Azure stemcell persistent disk formatting - Fixes Warden stemcells SSH access

3363.1

Release Date: February 15, 2017

Reported Problems: - DO NOT USE *azure* stemcell as it may cause data loss. - [Out of memory errors still exists in Kernel 4.4.0.62](#) - will be fixed around Feb 20.

Changes: - Fixes double -hvm- suffix problem for AWS Light stemcells

3363

Release Date: February 15, 2017

Reported Problems: - DO NOT USE *azure* stemcell as it may cause data loss. - [Out of memory errors still exists in Kernel 4.4.0.62](#) - will be fixed around Feb 20. - rsyslog version updated to 8.24.0, regressing on issue #1537 - AWS Light stemcell has incorrect name once imported - BOSH SSH does not work on BOSH Lite

Changes: - Add more auditd rules - Fix CentOS initramfs to load necessary kernel modules - Disable boot loader login - Increasing tcp_max_sync_backlog - Disabling any DSA host keys - Add `bosh_sshers` group and assign it to vcap user - Only allow users in `bosh_sshers` group to SSH

Agent: - Log Agent API access events in CEF format to syslog (vcap.agent topic) - Allow configuring swap size through `env.bosh.swap_size` (example: `env.bosh.swap_size: 0`) - Prepare for SHA2 releases - Allow setting fetching to work with base64 encoded user data - Do not delaycompress in logrotate

3312.x

This section includes release notes for the 3312 line of Linux stemcells used with Pivotal Cloud Foundry (PCF).

3312.51

Release Date: January 23, 2018

- Bump Ubuntu Trusty stemcells for [USN-3540-2: Linux kernel \(Xenial HWE\) vulnerabilities](#) [↗](#) (This flaw is known as Spectre.)

3312.50

Release Date: January 10, 2018

- Bump Ubuntu Trusty stemcells for [USN-3522-4: Linux kernel \(Xenial HWE\) regression](#) [↗](#)
- Configure vSphere stemcells to use VM hardware version 9 (requires ESXi 5.1) to be compatible with <https://www.vmware.com/us/security/advisories/VMSA-2018-0004.html> [↗](#)

3312.49

Release Date: January 09, 2018

- Bump Ubuntu Trusty stemcells for [USN-3522-2: Linux \(Xenial HWE\) vulnerability](#) [↗](#) (This flaw is known as Meltdown.)

3312.48

Release Date: December 08, 2017

- Bump Ubuntu Trusty stemcell USN-3509-2: Linux kernel (Xenial HWE) vulnerabilities

3312.47

Release Date: December 06, 2017

- Bump Ubuntu Trusty stemcells for USN-3505-1: Linux firmware vulnerabilities

3312.46

Release Date: November 21, 2017

- Periodic Ubuntu stemcells update

3312.17

Release Date: January 31, 2017

Reported Problems: - [Memory leak bug in Kernel 4.4.0-59](#) [↗](#)

Changes: - Periodic stemcell update

3312.15

Release Date: January 12, 2017

Reported Problems: - [Memory leak bug in Kernel 4.4.0-59](#) [↗](#)

Changes: - Periodic stemcell update

3312.12

Release Date: December 20, 2016

- Lock down rsyslog to 8.22.0 to avoid high memory usage issue <https://github.com/cloudfoundry/bosh/issues/1537> ↗

3312.9

Release Date: December 15, 2016

- Updates Azure Ubuntu stemcells to use parted partitioner to fix slow disk partitioning
 - Related issue: <https://github.com/cloudfoundry-incubator/bosh-azure-cpi-release/issues/227> ↗

3312.8

Release Date: December 14, 2016

- Bumps Ubuntu stemcells for USN-3156-1: APT vulnerability

3312.7

Release Date: December 06, 2016

- Bump Ubuntu stemcells for [USN-3151-2: Linux kernel \(Xenial HWE\) vulnerability](#) ↗

3312.6

Release Date: December 02, 2016

- Periodic stemcell update

3312.3

Release Date: November 30, 2016

- Periodic stemcell update
 - Includes [USN-3134-1](#) ↗ as requested by a community member

3312

Release Date: November 16, 2016

- Properly includes `libpam_cracklib.so` to avoid errors in `/var/log/auth.log`

3309.x

This section includes release notes for the 3309 line of Linux stemcells used with Pivotal Cloud Foundry (PCF).

3309

Release Date: November 10, 2016

- Fixes persistent disk mounting on OpenStack described in [Stemcell 3308](#) ↗

3308.x

This section includes release notes for the 3308 line of Linux stemcells used with Pivotal Cloud Foundry (PCF).

3308

Release Date: November 09, 2016

Reported Problems: - On OpenStack: Mounting persistent disks not working when using `config-drive: disk` while nova is configured to use a `cdrom` config-drive due to <https://github.com/cloudfoundry/bosh/issues/1503>

Fixes: - Fixes SSH key installation issue introduced in [Stemcell 3306](#)

3306.x

This section includes release notes for the 3306 line of Linux stemcells used with Pivotal Cloud Foundry (PCF).

3306

Release Date: November 08, 2016

Reported Problems - `bosh-init` doesn't work with this stemcell on OpenStack and AWS due to <https://github.com/cloudfoundry/bosh/issues/1500> - Booting the stemcell image directly in you IaaS (without using BOSH/bosh-init) does no longer provision the ssh key for user `vcap`, so you need to login differently

Changes - Agent will now wait for monit to complete stop all processes before carrying on - Added google stemcells - Default `dmesg_restrict` to 1 - Disable all IPv6 configurations - Reenabled UDF kernel module for Azure - Increase `root_maxkeys` and `maxkeys` kernel configurations - Changed default hostname to `bosh-stemcell` instead of `localhost` to avoid boot problems on GCP - Lower TCP keepalive configuration by default - Mount `/var/log` directory to `/var/vcap/data/root_log` - Restrict Access to the `su` command - Add `pam_cracklib` requirements to `common-password` and `password-auth` - Enable auditing for processes that start prior to `auditd` - Set log rotation interval to 15 min in stemcell - Made ownership & permissions for `/etc/cron*` files more restrictive - Customize shell prompt to show instance name and ID - Removed floppy drives from vSphere stemcells - Removed `bosh micro` assets hence

making `bosh micro` unsupported

Misc: - Stemcells are now built through Concourse via <https://main.bosh-ci.cf-app.com/teams/main/pipelines/bosh:stemcells>

3263.x

This section includes release notes for the 3263 line of Linux stemcells used with Pivotal Cloud Foundry (PCF).

3263.10

Release Date: November 03, 2016

- Updates CentOS kernel to the latest version for "Dirty COW"
 - Ubuntu stemcells were updated in previous versions at the time of Ubuntu USN updates
- Includes fix to the bosh-agent to better support 1TB+ disk partitioning

3263.8

Release Date: October 21, 2016

- Bump Ubuntu stemcells for USN-3106-2: Linux kernel (Xenial HWE) vulnerability
- Includes a fix to the bosh-agent to work more reliably with 2TB+ persistent disks

3263.7

Release Date: October 12, 2016

- Bump Ubuntu stemcells for USN-3099-2: Linux kernel (Xenial HWE) vulnerabilities

3263.5

Release Date: September 30, 2016

- Periodic bump
- Delay start of rsyslogd using systemd on CentOS

3263.4

Release Date: September 28, 2016

- google-kvm: improve the `google-*` daemon configurations
 - fixes `ssh: handshake failed` errors on boot

3263.3

Release Date: September 26, 2016

- Bumps Ubuntu stemcells for [USN-3087-2](#) (OpenSSL regression)

3263

Release Date: September 19, 2016

- Bumps Ubuntu to Linux kernel to 4.4

Based on 3262 stemcells. **Note:** OpenStack stemcells series 3263 is broken due to <https://github.com/cloudfoundry/bosh-agent/issues/98> and should not be used

3262.x

This section includes release notes for the 3262 line of Linux stemcells used with Pivotal Cloud Foundry (PCF).

3262.21

Release Date: October 13, 2016

- Bump Ubuntu stemcells for USN-3099-2: Linux kernel (Xenial HWE) vulnerabilities

3262.19

Release Date: September 28, 2016

- google-kvm: improve the `google-*` daemon configurations
 - fixes `ssh: handshake failed` errors on boot

3262.16

Release Date: September 26, 2016

- Bumps Ubuntu stemcells for [USN-3087-2](#) (OpenSSL regression)

3262.15

Release Date: September 23, 2016

- Bumps Ubuntu stemcells for USN-3087-1: OpenSSL vulnerabilities

3233.x

This section includes release notes for the 3233 line of Linux stemcells used with Pivotal Cloud Foundry (PCF).

3233.1

Release Date: September 27, 2016

- Bumps Ubuntu stemcells for [USN-3087-2](#) (OpenSSL regression)

USN-3522-2 Addresses Meltdown Vulnerabilities

Meltdown exploits critical vulnerabilities in modern processors. For more information about Meltdown, see the [Meltdown and Spectre Attacks](#) blog post. [USN-3522-2](#) addresses the critical vulnerability in Ubuntu associated with Meltdown.

This update may include degradations to performance if your VM's CPU and memory usage are currently at near-capacity levels. Prior to upgrading to this stemcell, monitor your PCF VM's current CPU and memory usage and scale those components if necessary. If any of your VMs are currently operating at 60% or above, Pivotal recommends scaling that VM. For more information about the performance impact of Meltdown-related stemcell patches on PCF components and guidance on scaling, see this [KB article](#).

For more information about monitoring and scaling PCF, see the [Monitoring PCF VMs from Ops Manager](#), [Key Capacity Scaling Indicators](#), and [Scaling PAS](#) topics. Performance degradation is likely to vary by workload type, IaaS, and other factors. Pivotal recommends testing your deployment thoroughly after upgrading to this stemcell.

3232.x

This section includes release notes for the 3232 line of Linux stemcells used with Pivotal Cloud Foundry (PCF).

3232.21

Release Date: September 26, 2016

- Bumps Ubuntu stemcells for [USN-3087-2](#) (OpenSSL regression)

Stemcell v1709.x (Windows Server version 1709) Release Notes

This topic includes release notes for Windows stemcells used with Pivotal Application Service for Windows (PASW).

To download a stemcell, see [Stemcells for PCF \(Windows\)](#) on Pivotal Network.

 **Note:** The Windows stemcell v1709.x line is compatible with PASW v2.1 and v2.2.

1709.21

Release Date: May 30, 2019

Security Fix

- Based on [Microsoft's guidance](#), additional fixes to protect against speculative execution side-channel vulnerabilities

1709.21

Release Date: May 23, 2019

Features

- Platform Engineers can deploy Windows Stemcells on a BOSH Director with Google Cloud Storage as their external Blobstore.
- Improved Troubleshooting of Windows VMs, with ssh enabled by default for all Windows VMs. You can still disable SSH in the PASW tile.

1709.20

Features

- Intended for use with [April 2019 Microsoft Security Updates](#)

1709.19

Features

- Includes [March 2019 Microsoft Security Updates](#).

Bug Fix

- Disabled additional configuration related to NetBios. See the Pivotal Tracker [story](#).

1709.18

Release Date: March 1, 2019

- [Patches] Included [February Patch Tuesday Microsoft Security Updates](#).

1709.17

Release Date: January 24, 2019

- [Patches] Included [January Patch Tuesday Microsoft Security Updates](#).
- Added [fix](#) for mitigating CVE-2018-3639.

1709.16

Release Date: December 24, 2018

Features

- [Patches] Included [December Patch Tuesday Microsoft Security Updates](#).
- Added the BOSH API version in the stemcell to surface more information about the compatibility of the stemcell with BOSH.

Bug Fix

- BOSH release job symlinks were not getting cleaned up when a target folder was removed. This issue is resolved.

1709.15

Release Date: November 28, 2018

Features

- [Security] Disabled use of TLS 1.0 by SSL/TLS server and client.
- [Security] Disabled RC4.
- [Security] Disabled triple-DES cipher to mitigate against Sweet32: Birthday attacks on 64-bit block ciphers in TLS.
- [Patches] Intended for use with [November 2018 Patch Tuesday Microsoft Security Updates](#).
- [New IaaS Support] Added support for AWS GovCloud.

1709.14

Release Date: October 30, 2018

Features

- Intended for use with [October 2018 Microsoft Security Updates](#).
- Disables RDP by default to improve security of the 1709 stemcells. You can still enable RDP through the PASW Tile Configuration.

Bug Fix

- Intermittent “Access denied” errors occur during the compilation phase of PASW deployments. We have added a fix to potentially resolve them.
- Fixed the Ephemeral Disk Provisioning for Azure enabling compatibility of PASW’s ephemeral disk functionality with OpsMgr on Azure.

1709.13

Release Date: September 24, 2018

Features

- Includes ephemeral disk support. This enables you to configure the size of your Windows cells in the PAS for Windows tile. For more information, see the [Configure Tile Resources](#) section in *Installing and Configuring PAS for Windows*.
- Intended for use with [September 2018](#) Microsoft Security Updates.

Bug Fix

- Previously, the `os_version` argument was mandatory during the `Invoke-Sysprep` step. The OS is now detected by default, and the `os_version` argument is optional.

Known Issues

- For Google Cloud Platform (GCP) users, a bug in PASW causes outbound connections from applications deployed on PASW with this stemcell version to fail. The resolution will come in patch versions of PASW v2.1, v2.2 and v2.3.

1709.12

Release Date: August 27, 2018

Features

- Intended for use with the [August 2018](#) Microsoft Security Updates.
- Includes an important Microsoft Security Update that provides protections against a new speculative execution side-channel vulnerability known as L1 Terminal Fault (L1TF). For more information, see [Windows Support](#).
- Compatible with the latest stable OpenSSH version, `OpenSSH_for_Windows_v7.7.2.0p1-Beta`. This version fixed the issue of OpenSSH logs filling up the disk.

Bug Fix

- Deployment of PASW fails due to “Access is Denied” error during compilation of packages on the Windows VM.

1709.11

Release Date: August 2, 2018

Features

This is the first official release of the 1709 stemcell for Amazon Web Services (AWS). PASW can be deployed on AWS going forward.

Improvements

This release incorporates [Patch Tuesday July 2018](#) security updates.

Bug Fix

Previously, when operators selected the **Encrypt Linux EBS Volumes** checkbox in the IaaS-specific configuration section of the BOSH Director tile, the deployment of PASW would fail.

This release enables operators to select the **Encrypt Linux EBS Volumes** checkbox without the deployment of PASW failing. However, only Linux VMs will be encrypted, not Windows VMs.

vSphere Stemcell

The source code and other assets are available on [GitHub](#).

1709.10

Release Date: June 27, 2018

Bug Fix

- Updated the bosh-davcli and the bosh-s3cli to the latest.
- Repairs NTP. Specifically, run time sync command via Powershell to strip quotes from NTP server. See the Pivotal Tracker [story](#).

The source code and other assets are available on [GitHub](#).

1709.8

Release Date: June 1, 2018

Bug Fix

- Includes a fix to support syncing as stated by Microsoft even when the time is drastically off.

The source code and other assets are available on [GitHub](#).

1709.7

Release Date: May 24, 2018

Improvements

- Disabled root disk resizing for the 1709 AWS stemcell.

The source code and other assets are available on [GitHub](#).

1709.6

Release Date: May 18, 2018

Improvements

- Intended for use with [May 2018](#) Microsoft security updates.

The source code and other assets are available on [GitHub](#).

1709.5

Release Date: May 8, 2018

Improvements

- Intended for use with [April 2018](#) [Microsoft security updates](#).
- Disabled root disk resizing and provided large root disks by default. For more information, see [Windows Stemcells v1709.5-v1709.12](#) [in *Installing and Configuring PAS for Windows*](#).

The source code and other assets are available on [GitHub](#) [.](#)

1709.4

Release Date: March 20, 2018

Note

- You must **enable** the Meltdown and Spectre patch for it to function. See [Creating a vSphere Stemcell by Hand](#) [in GitHub](#) for instruction to enable the patch.

Improvements

- Intended for use with March 2018 Microsoft security updates.
- Intended for use with [KB4056892](#) [that addresses Microsoft's guidance for protection against speculative execution side-channel vulnerabilities](#) [.](#) See Microsoft's *Known Issues* listed in the [KB article](#) [for the patch](#).

Source code and other assets on [GitHub](#) [.](#)

1709.3

Release Date: February 21, 2018

Note

- You must **enable** the Meltdown and Spectre patch for it to function. See [Creating a vSphere Stemcell by Hand](#) [in GitHub](#) for instruction to enable the patch.

Improvements

- Intended for use with February 2018 Microsoft security updates.
- Intended for use with [KB4056892](#) [that addresses Microsoft's guidance for protection against speculative execution side-channel vulnerabilities](#) [.](#) See Microsoft's *Known Issues* listed in the [KB article](#) [for the patch](#).

Fixes

- Fix BOSH ssh when stemcell is operating as a Diego Cell.

Source code and other assets on [GitHub](#) [.](#)

Tiles Using Xenial Stemcells in PCF

This table provides a quick reference of PCF product versions that are now using Xenial stemcells.

Products Using Xenial Stemcells

If a product is not yet listed, the product still uses Trusty stemcells.

| Product/Component | Starting Version | Release Notes Link |
|-----------------------------------|------------------|---|
| PCF Operations Manager | v2.3 | Release Notes  |
| Pivotal Application Service (PAS) | v2.3 | Release Notes  |
| Pivotal Container Service (PKS) | v1.2 | Release Notes  |
| PCF Event Alerts | v1.2.3 | Release Notes  |
| Metrics Forwarder for PCF | v1.11.3 | Release Notes  |
| MySQL for PCF | v2.4 | Release Notes  |
| RabbitMQ for PCF | v1.14.1 | Release Notes  |
| Redis for PCF | v1.14.0 | Release Notes  |
| Scheduler for PCF | v1.2.3 | Release Notes  |
| Single Sign-On (SSO) for PCF | v1.7.1 | Release Notes  |
| Spring Cloud Data Flow | v1.2.0 | Release Notes  |
| Spring Cloud Services for PCF | v2.0.2 | Release Notes  |

Xenial Stemcell Support in Ops Manager

You can import and use Xenial stemcell-based tiles in the following versions of Ops Manager:

- v2.1.15 and later
- v2.2.2 and later
- v2.3.x and later

For more information about the introduction of Xenial stemcells to your PCF deployment, see [Updates for Xenial Stemcell Support](#)  in the *Pivotal Cloud Foundry v2.3 Breaking Changes Release Notes*.

Platform Architecture and Planning

This documentation describes reference architectures and other plans for installing Pivotal Cloud Foundry (PCF) on any infrastructure to support the runtime environments Pivotal Application Service (PAS) and Pivotal Container Service (PKS).

Overview

A Pivotal Cloud Foundry (PCF) reference architecture describes a proven approach for deploying PCF on a specific IaaS, such as AWS, Azure, GCP, OpenStack, or vSphere. PCF reference architectures meet the following requirements:

- Secure
- Publicly-accessible
- Includes common PCF-managed services such as MySQL, RabbitMQ, and Spring Cloud Services
- Can host at least 100 app instances, or far more
- Have been deployed and validated by Pivotal to support Ops Manager, PAS, and PKS

You can use PCF reference architectures to help plan the best configuration for your PCF deployment on your IaaS.

Reference Architecture and Planning Topics

All PCF reference architectures start with the [Base PAS Architecture](#) and [Base PKS Architecture](#), below.

The following infrastructure-specific topics build on these two common base architectures:

- [AWS Reference Architecture](#)
- [Azure Reference Architecture](#)
- [GCP Reference Architecture](#)
- [OpenStack Reference Architecture](#)
- [vSphere Reference Architecture](#)

The following topic describes a broader architecture that automates the installation and updating of multiple PCF foundations, multiple instances of each architecture above:

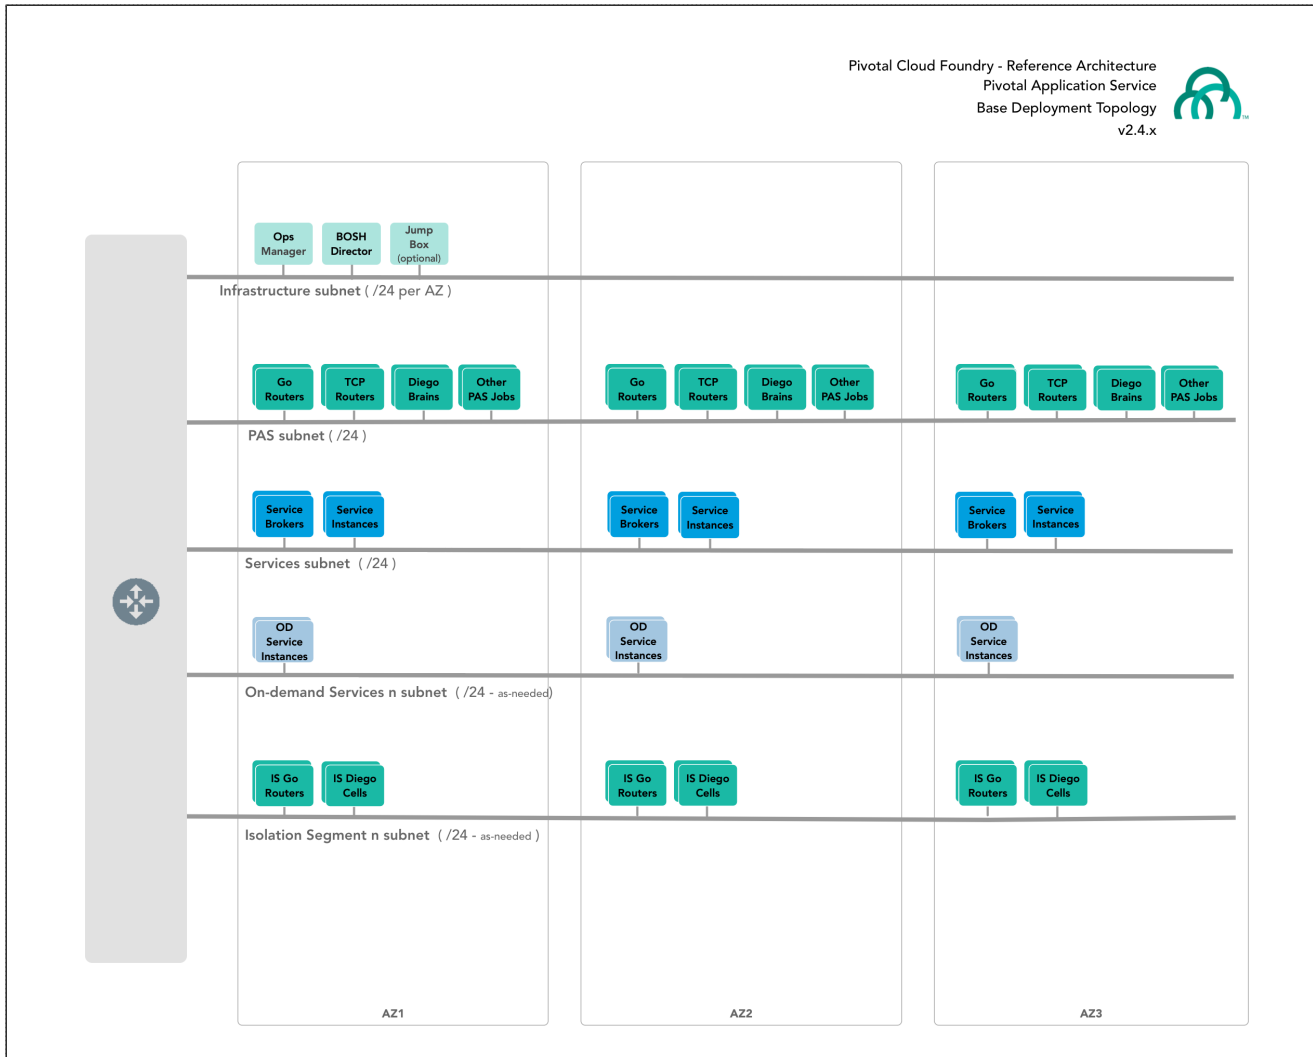

- [Control Plane Reference Architectures](#)

The following topics address aspects of platform architecture and planning that the PCF reference architectures do not cover:

- [Implementing a Multi-Foundation PKS Deployment](#)
- [Using Global DNS Load Balancers for Multi-Foundation](#)

PAS Architecture

The following diagram shows a base architecture for PAS, and how its network topology places and replicates PCF and PAS components across subnets and Availability Zones.

[View a larger version of this diagram](#)

Internal Components

The following table describes the internal component placements shown in the diagram above:

| Component | Placement and Access Notes |
|--------------------------------|---|
| Ops Manager | Deployed on one of the three public subnets. Accessible by FQDN or through an optional jumpbox. |
| BOSH Director | Deployed on the infrastructure subnet. |
| Jumpbox | Optional. Deployed on the infrastructure subnet for accessing PAS management components such as Ops Manager and the Cloud Foundry command-line interface (cf CLI). |
| Gorouters (HTTP routers in CF) | Deployed on all three PAS subnets, one per Availability Zone (AZ). Accessed through the HTTP, HTTPS, and SSL load balancers. |
| Diego Brain | Deployed on all three PAS subnets, one per AZ. The Diego Brain component is required, but SSH container access support through the Diego Brain is optional, and enabled through the SSH load balancers. |
| TCP Routers | Optional. Deployed on all three PAS subnets, one per AZ, to support TCP routing. |
| Service Tiles | Service brokers and shared services instances are deployed to the Services subnet. Dedicated on-demand service instances are deployed to an On-demand services subnet. |
| Isolation Segments | Deployed on an Isolation Segment subnet. Includes Diego Cells and Gorouters for running and accessing apps hosted within isolation segments. |

Networks

Pivotal recommends defining your networks and load-balancing their incoming requests as follows:

Required Subnets

PAS requires the following statically-defined networks to host its main component systems.

- Infrastructure subnet - `/24` segment This subnet contains VMs that require access only for Platform Administrators, for example Ops Manager, the BOSH Director, and an optional jumpbox.
- PAS subnet - `/24` segment This subnet contains PAS runtime VMs, such as Gorouters, Diego Cells and Cloud Controllers.
- Services subnet - `/24` segment The Services and On-Demand Services networks support Ops Manager tiles that you might add in addition to PAS. You can think of them as the “everything not PAS” networks. Some services tiles can call for additional network capacity to grow into on-demand. If you use services with this capability, Pivotal recommends that you add an On-Demand Services network for each on-demand service, as described below.
- On-Demand Services subnet(s) - `/24` segments This is for services that can allocate network capacity on-demand from BOSH for their worker VMs; see the Services subnet above. Pivotal recommends allocating a dedicated subnet to each on-demand service. For example, you can configure the Redis tile as follows:
 - **Network:** enter the existing `Services` network, to host the service broker
 - **Services Network:** deploy a new network `OD-Services1`, to host the Redis worker VMs

Another on-demand service tile can then also use `Services` for its broker and a new `OD-Services2` network for its workers, and so on.

- Isolation Segments subnet(s) - `/24` segments You can add one or more Isolation Segment tiles to an PAS installation to compartmentalize hosting and routing resources. For each Isolation Segment you deploy, you should designate a `/24` network for its range of address space.

Load Balancing

Any PAS installation needs a suitable load balancer to send incoming HTTP, HTTPS, SSH, and SSL traffic to its Gorouters and application containers. All installations approaching production-level use rely on external load balancing from hardware appliance vendors or other network-layer solutions.

The load balancer can also perform Layer 4 or Layer 7 load balancing functions. SSL can be terminated at the load balancer or used as a pass-through to the Gorouter.

Common deployments of load balancing in PAS are:

- HTTP/HTTPS traffic to and from Gorouters
- TCP traffic to and from TCP routers
- Traffic from the Diego Brain, when developers access app containers via SSH

To balance load across multiple PAS foundations, use an IaaS- or vendor-specific Global Traffic Manager or Global DNS load balancer.

For additional information, see [Global DNS Load Balancers for Multi-Foundation Environments](#).

High Availability

PAS is not considered High Availability (HA) until it runs across at least two Availability Zones (AZs). Pivotal recommends defining three AZs.

On IaaSes with their own HA capabilities, using the IaaS HA in conjunction with a PCF HA topology provides the best of both worlds. Multiple AZs give PCF redundancy, so that losing an AZ is not catastrophic. The BOSH Resurrector can then replace lost VMs as needed to repair a foundation.

To back up and restore a foundation externally, use BOSH Backup and Restore (BBR). For more information, see the [BOSH Backup and Restore](#) documentation.

Storage

PAS requires disk storage for each component, for both persistent data and to allocate to ephemeral data. You size these disks in the **Resource Config** pane of the PAS tile. For details on storage configuration and capacity planning, see the corresponding chapter for the specific IaaS.

The platform also requires you to configure file storage for large shared objects. These blobstores can be external or internal. For details, see the

Configure File Storage step in the *Deploying PAS* topic for your IaaS, and the [Configure File Storage](#) section in the *Configuring PAS for Upgrade* topic.

Security

See the topics below for how PAS implements security:

- [PCF Infrastructure Security](#) 
- [Security Concepts](#) 
- [Certificates and TLS in PCF](#)
- [Network Communication Paths in PCF](#)  - includes firewall ports

Domain Names

PAS requires following domain names to be registered:

- System domain, for PAS and other tiles: `sys.domain.name`
- App domain, for your applications: `app.domain.name`

You must also define the following wildcard domain names and include them when creating certificates that access PAS and its hosted apps:

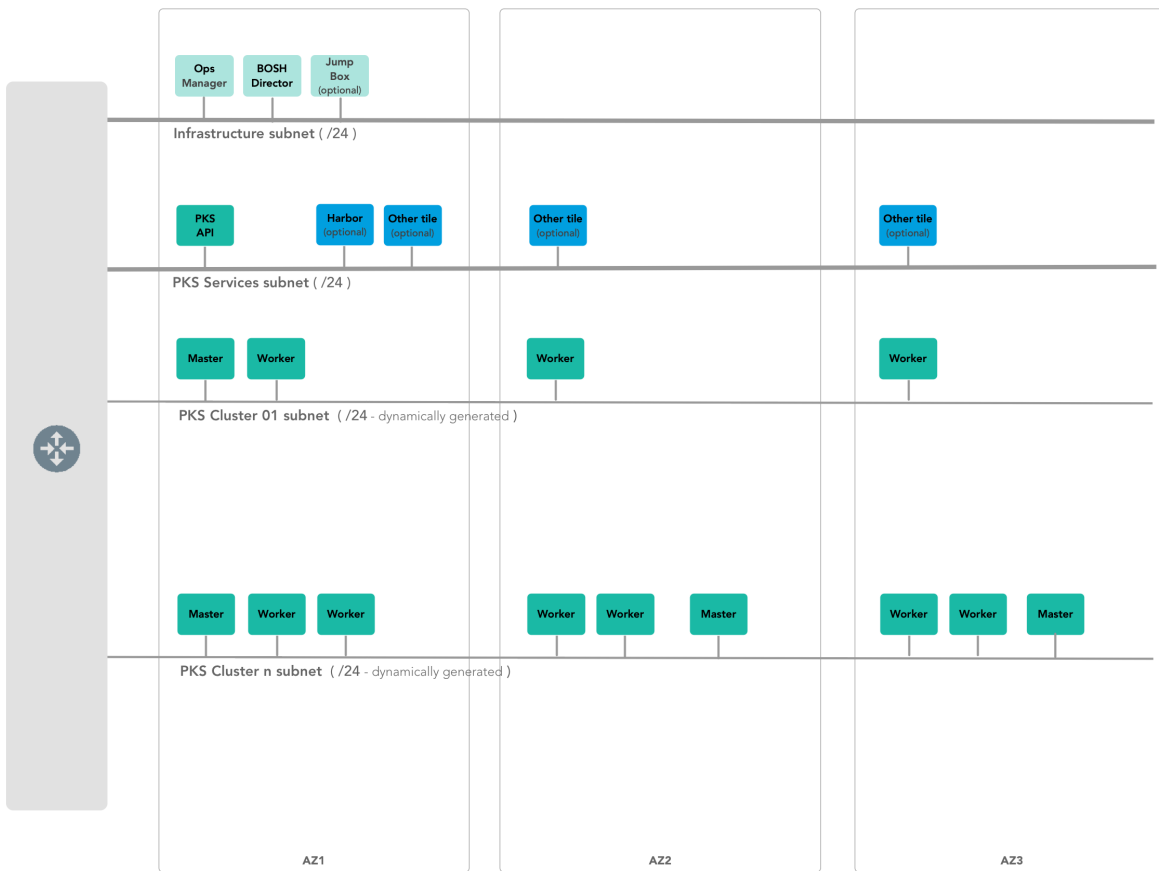

- *.SYSTEM-DOMAIN
- *.APPS-DOMAIN
- *.login.SYSTEM-DOMAIN
- *.uaa.SYSTEM-DOMAIN

Component Scaling

See [Scaling PAS](#) for recommendations on how to scale PAS for different deployment scenarios.

PKS Architecture

The following diagram shows a base architecture for PKS, and how its network topology places and replicates PCF and PKS components across subnets and Availability Zones.

[View a larger version of this diagram](#)

Internal Components

The following table describes the internal component placements shown in the diagram above:

| Component | Placement and Access Notes |
|---------------|---|
| Ops Manager | Deployed on one of the subnets. Accessible by fully-qualified domain name (FQDN) or through an optional jumpbox. |
| BOSH Director | Deployed on the infrastructure subnet. |
| Jumpbox | Optional. Deployed on the infrastructure subnet for accessing PKS management components such as Ops Manager and the PKS + Kubectl command-line interface. |
| PKS API | Deployed as a service broker VM on the PKS Services subnet. Handles PKS API and service adapter requests, and manages PKS clusters. For more information, see Pivotal Container Service (PKS) . |
| Harbor Tile | Optional container images registry, typically deployed to the Services subnet. |
| PKS Cluster | Deployed to a dynamically-created, dedicated PKS cluster subnet. Each cluster consists of worker nodes that run the workloads (applications) and one or more master nodes. |

Networks

Pivotal recommends defining your networks and load-balancing their incoming requests as follows:

Subnets Requirements

PKS requires two defined networks to host the main elements that compose it.

- Infrastructure subnet - `/24` Contains VMs that require access only for Platform Administrators, for example Ops Manager, BOSH Director and an optional jumpbox.
- PKS Services subnet - `/24` Hosts PKS API VM and other optional service tiles such as Harbor.
- PKS Clusters subnets - each one a `/24` from a pool of pre-allocated IPs Hosts PKS clusters.

Load Balancing

Load balancers can be used to manage traffic across master nodes of a PKS cluster or for deployed workloads. For more information on how to configure load balancers for PKS, refer to the corresponding documentation for the specific IaaS.

High Availability

PKS has no inherent HA capabilities to design for. Make the best efforts to have HA design at the IaaS, storage, power and access layers to support PKS.

Storage

PKS requires shared storage across all Availability Zones for the deployed workloads to appropriately allocate their required storage.

Security

See the topics below for how PKS implements security:

- [Enterprise PKS Security](#) 
- [Firewall Ports](#) 

Domain Names

PKS requires the following domain names to be registered when creating a wildcard certificate and PKS tile configurations: `*.pks.domain.name`

The wildcard certificate covers both the PKS API domain e.g. `api.pks.domain.name` and the PKS Clusters domains e.g. `mycluster.pks.domain.name`.

Cluster Management

See [Managing Clusters](#)  for recommendations on managing Enterprise PKS clusters.

| Component | Reference Architecture Notes |
|---|---|
| Domains & DNS | <p>CF Domain Zones and routes in use by the reference architecture include:</p> <ul style="list-style-type: none"> domains for *.apps and *.sys (required) a route for Ops Manager (required) a route for ssh access to app containers (optional) <p>Using Route 53 to manage domains is optional.</p> |
| Ops Manager | Deployed on one of the three public subnets and accessible by FQDN or through an optional jumpbox. |
| BOSH Director | Deployed on the infrastructure subnet. |
| Elastic Load Balancers - HTTP, HTTPS, and SSL | Required. Load balancer that handles incoming HTTP, HTTPS, and SSL traffic and forwards them to the Gorouters. Deployed on all three public subnets. |
| Elastic Load Balancers - SSH | Optional. Load balancer that provides SSH access to app containers. Deployed on all three public subnets, one per AZ. |
| Gorouters | Accessed through the HTTP, HTTPS, and SSL Elastic Load Balancers. Deployed on all three Pivotal Application Service (PAS) subnets, one per AZ. |
| Diego Brains | Required. However, the SSH container access functionality is optional and enabled through the SSH Elastic Load Balancers. Deployed on all three PAS subnets, one per AZ. |
| TCP Routers | Optional feature for TCP routing. Deployed on all three PAS subnets, one per AZ. |
| CF Database | Reference architecture uses AWS RDS. Deployed on all three RDS subnets, one per AZ. |
| Storage Buckets | Reference architecture uses 4 S3 buckets: buildpacks, droplets, packages, and resources. |
| Service Tiles | Deployed on all three service subnets, one per AZ. |
| Service User & Roles | <p>One IAM role and one IAM user are recommended: the IAM role for Terraform, and the IAM user for Ops Manager and BOSH. Consult the following list:</p> <ul style="list-style-type: none"> Admin Role: Terraform uses this IAM role to provision required AWS resources as well as an IAM user. IAM User: This IAM user with IAM security credentials (access key ID and secret access key) is automatically provisioned with restrict access only to resources needed by PCF. |
| EC2 Instance Quota | The default EC2 instance quota on a new AWS subscription only has around 20 EC2 instances, which is not enough to host a multi-AZ deployment. The recommended quota for EC2 instances is 100. AWS requires the instances quota tickets to include Primary Instance Types, which should be t2.micro. |

Network Objects

The following table lists the network objects in this reference architecture.

| Network Object | Notes | Estimated Number |
|-------------------------------|--|------------------|
| External Public IPs | One per deployment, assigned to Ops Manager. | 1 |
| Virtual Private Network (VPC) | One per deployment. A PCF deployment exists within a single VPC and a single AWS region, but should distribute PCF jobs and instances across 3 AWS AZs to ensure a high degree of availability. | 1 |
| Subnets | <p>The reference architecture requires the following subnets:</p> <ul style="list-style-type: none"> 1 x (/24) infrastructure (BOSH Director) subnet 3 x (/24) public subnets (Ops Manager, Elastic Load Balancers, NAT instances), one per AZ 3 x (/20) PAS subnets (Gorouters, Diego Cells, Cloud Controllers, etc.), one per AZ 3 x (/20) services subnets (RabbitMQ, MySQL, Spring Cloud Services, etc.), one per AZ 3 x (/24) RDS subnets (Cloud Controller DB, UAA DB, etc.), one per AZ. | 13 |
| | This reference architecture requires 4 route tables: one for the public subnet, and one each for all 3 private subnets across 3 AZs. Consult the following list: | |

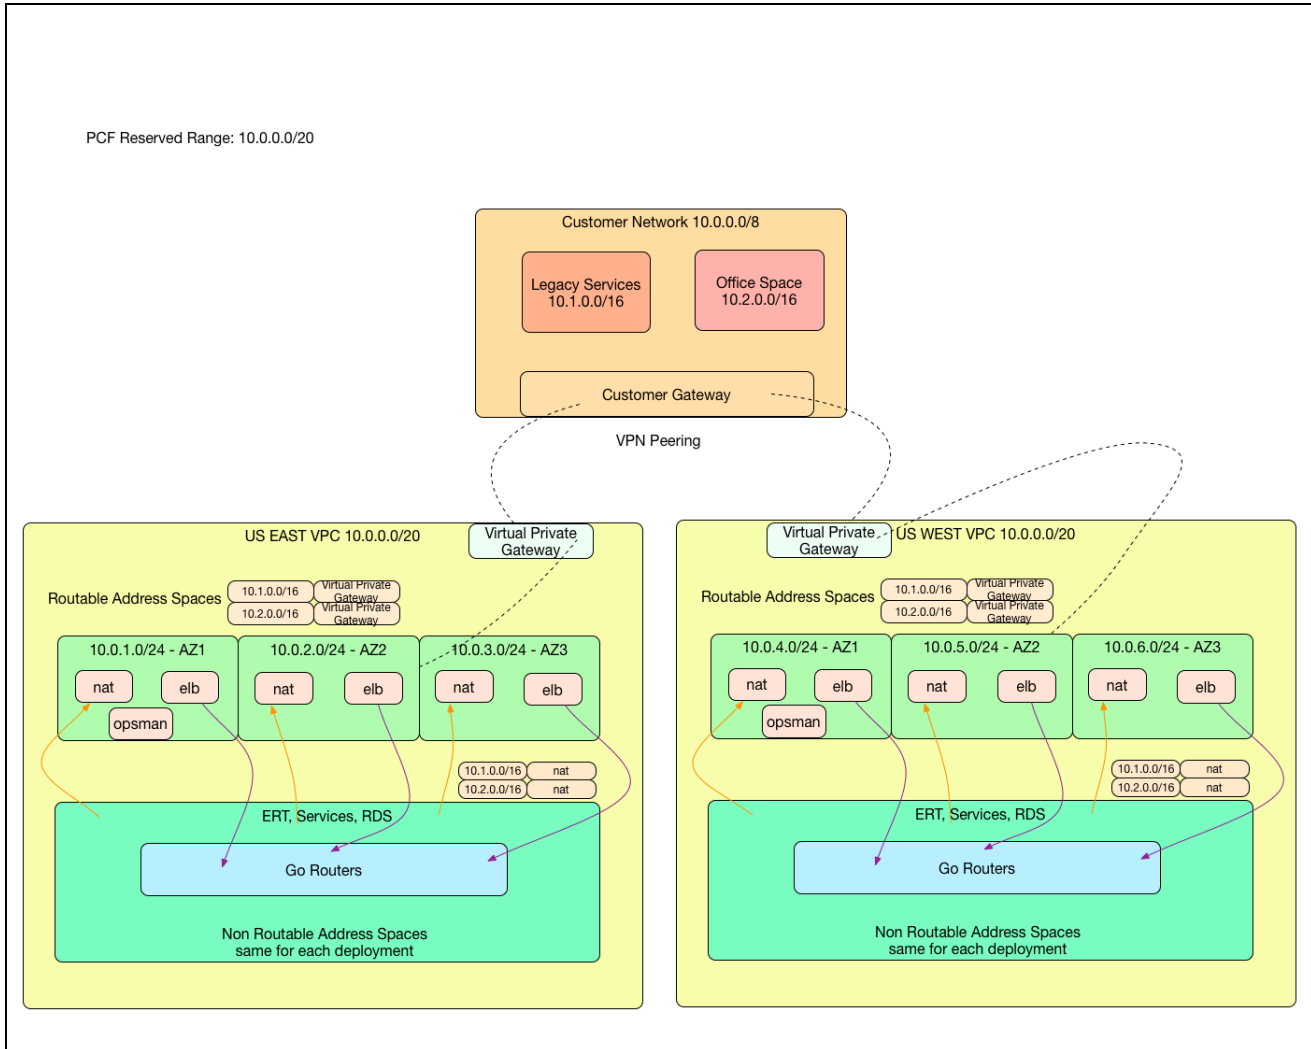

| Route Tables | <ul style="list-style-type: none">PublicSubnetRouteTable: This routing table enables the ingress/egress routes from/to Internet through the Internet gateway for Ops Manager and the NAT Gateway.PrivateSubnetRouteTable: This routing table enables the egress routing to the Internet through the NAT Gateway for the BOSH Director and PAS. <p>For more information, see the Terraform script that creates the route tables and the script that performs the route table association.</p> <div><p>Note: If an EC2 instance sits on a subnet with an Internet gateway attached as well as a public IP address, it is accessible from the Internet through the public IP address; for example, Ops Manager. PAS needs Internet access due to the access needs of using an S3 bucket as a blobstore.</p></div> | 4 | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|-----------------|---|----------------|---------------|--|----------|-------------|----------|-------------|-----------|------|------------------------------|----------|-------------|-----------|-------|--|--------|-------------|----------|-----|--|-----------|------------------|----------|-----|--|-------|----|-----------|-----|-------------|-------|-----|-----------|-----|--------------|-------|------|-----------|-----|--|----------|------|-----------|-----|------------------------------|---|
| Security Groups | <p>The reference architecture requires 5 Security Groups. For more information, see the Terraform Security Group rules script. The following table describes the Security Group ingress rules:</p> <div><p>Note: The extra port of 4443 with the Elastic Load Balancer is due to the limitation that the Elastic Load Balancer does not support WebSocket connections on HTTP/HTTPS.</p></div> <table><thead><tr><th>Security Group</th><th>Port</th><th>From CIDR</th><th>Protocol</th><th>Description</th></tr></thead><tbody><tr><td>OpsMgrSG</td><td>22</td><td>0.0.0.0/0</td><td>TCP</td><td>Ops Manager SSH access</td></tr><tr><td>OpsMgrSG</td><td>443</td><td>0.0.0.0/0</td><td>TCP</td><td>Ops Manager HTTP access</td></tr><tr><td>VmsSG</td><td>ALL</td><td>VPC_CIDR</td><td>ALL</td><td>Open up connections among BOSH-deployed VMs</td></tr><tr><td>MysqlSG</td><td>3306</td><td>VPC_CIDR</td><td>TCP</td><td>Enable network access to RDS</td></tr><tr><td>ElbSG</td><td>80</td><td>0.0.0.0/0</td><td>TCP</td><td>HTTP to PAS</td></tr><tr><td>ElbSG</td><td>443</td><td>0.0.0.0/0</td><td>TCP</td><td>HTTPS to PAS</td></tr><tr><td>ElbSG</td><td>4443</td><td>0.0.0.0/0</td><td>TCP</td><td>WebSocket connection to Loggregator endpoint</td></tr><tr><td>SshElbSG</td><td>2222</td><td>0.0.0.0/0</td><td>TCP</td><td>SSH connection to containers</td></tr></tbody></table> | Security Group | Port | From CIDR | Protocol | Description | OpsMgrSG | 22 | 0.0.0.0/0 | TCP | Ops Manager SSH access | OpsMgrSG | 443 | 0.0.0.0/0 | TCP | Ops Manager HTTP access | VmsSG | ALL | VPC_CIDR | ALL | Open up connections among BOSH-deployed VMs | MysqlSG | 3306 | VPC_CIDR | TCP | Enable network access to RDS | ElbSG | 80 | 0.0.0.0/0 | TCP | HTTP to PAS | ElbSG | 443 | 0.0.0.0/0 | TCP | HTTPS to PAS | ElbSG | 4443 | 0.0.0.0/0 | TCP | WebSocket connection to Loggregator endpoint | SshElbSG | 2222 | 0.0.0.0/0 | TCP | SSH connection to containers | 5 |

| Jumpbox | <p>Optional. Provides a way of accessing different network components. For example, you can configure it with your own permissions and then set it up to access to Pivotal Network to download tiles. Using a jumpbox is particularly useful in IaaS where Ops Manager does not have a public IP address. In these cases, you can SSH into Ops Manager or any other component through the jumpbox.</p> | 1 | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

Integrate PCF with Customer Data Center through VPN

At times, applications on PCF need to access on-premise data. The connection between an AWS VPC and an on-premise datacenter is made through [VPN peering](#). When employing non-VPN peering, there are several points to consider:

- Assign routable IP addresses with the following in mind:
 - It may not be realistic to request multiple routable /22 address spaces, due to IP exhaustion.
 - Using different VPC address spaces can cause snowflakes deployments and present difficulties in automation.
 - Only make the load balancer, NAT devices, and Ops Manager routable.

- PCF components can route egress through a NAT instance. As a result, operators do not need to assign routable IP addresses to PCF components.
- Inbound traffic from the datacenter should come through an [internal load balancer](#).
 - Outbound traffic to the datacenter should go through AWS NAT instances.

[View a larger version of this diagram](#).

Azure Reference Architecture

This guide presents a reference architecture for Pivotal Cloud Foundry (PCF) on Azure.

Azure does not provide resources in a way that translates directly to PCF availability zones. Instead, Azure provides high availability through fault domains and [availability sets](#).

All reference architectures described in this topic are validated for production-grade PCF deployments using fault domains and availability sets that include multiple job instances.

See [Azure on PCF Requirements](#) for general requirements for running PCF and specific requirements for running PCF on Azure.

PCF Reference Architectures

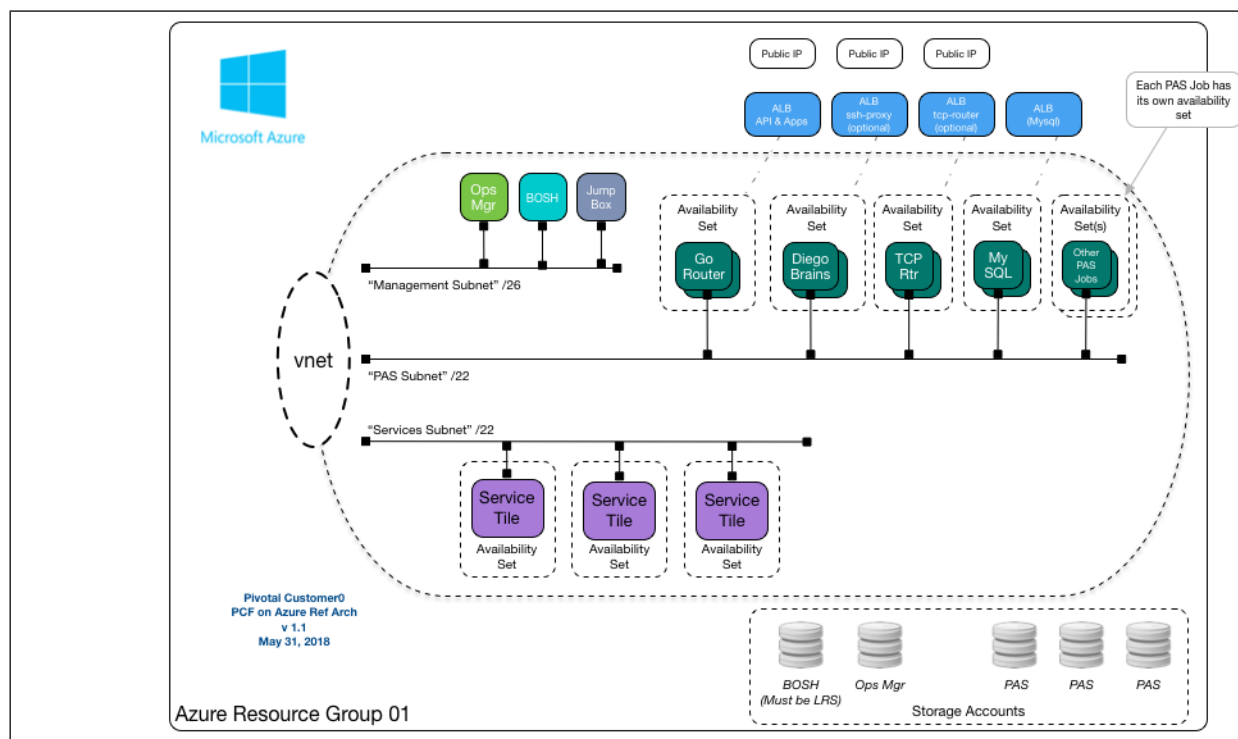

A PCF reference architecture describes a proven approach for deploying PCF on a specific IaaS, such as Azure, that meets the following requirements:

- Secure
- Publicly-accessible
- Includes common PCF-managed services such as MySQL, RabbitMQ, and Spring Cloud Services
- Can host at least 100 app instances, or far more

Pivotal provides reference architectures to help you determine the best configuration for your PCF deployment.

Base Azure Reference Architecture

The following diagram provides an overview of a reference architecture deployment of PCF on Azure.

[View a larger version of this diagram](#).

Base Reference Architecture Components

The following table lists the components that are part of a base reference architecture deployment on Azure using a single resource group.

| Component | Reference Architecture Notes |
|------------------------------------|--|
| Domains and DNS | CF Domain Zones and routes in use by the reference architecture include: <ul style="list-style-type: none"> domains for *.apps and *.system (required), a route for Ops Manager (required), a route for Doppler (required), a route for Loggregator (required), a route for SSH access to app containers (optional), and a route for TCP routing to apps (optional). |
| Ops Manager | Deployed on the management subnet and accessible by FQDN or through an optional jumpbox. |
| BOSH | Deployed on the management subnet. |
| Azure Load Balancer - API and Apps | Required. Load balancer that handles incoming API and apps requests and forwards them to the Gorouters. |
| Azure Load Balancer - ssh-proxy | Optional. Load balancer that provides SSH access to app containers. |
| Azure Load Balancer - tcp-router | Optional. Load balancer that handles TCP routing requests for apps. |
| Azure Load Balancer - MySQL | Required to provide high availability for MySQL backend to Pivotal Application Service (PAS). |
| Gorouters | Accessed through the API and Apps load balancer. Deployed on the PAS subnet, one job per Azure availability set. |
| Diego Brains | Required. However, the SSH container access functionality is optional and enabled through the SSH Proxy load balancer. Deployed on the PAS subnet, one job per Azure availability set. |
| TCP Routers | Optional feature for TCP routing. Deployed on the PAS subnet, one job per availability zone. |
| MySQL | Reference architecture uses internal MySQL provided with PCF. Deployed on the PAS subnet, one job per Azure availability set. |
| PAS | Required. Deployed on the PAS subnet, one job per Azure availability set. |
| Storage Accounts | PCF on Azure requires 5 standard storage accounts: BOSH, Ops Manager, and three PAS storage accounts. Each account comes with a set amount of disk. Reference architecture recommends using 5 storage accounts because Azure Storage Accounts have an IOPs limit of approximately 20k per account, which generally relates to a BOSH JOB/VM limit of approximately 20 VMs each. |
| Service Tiles | Deployed on the Services subnet. Each service tile is deployed to an availability set. |

Alternative Network Layouts for Azure

This section describes the possible network layouts for PCF deployments as covered by the reference architecture of PCF on Azure.

At a high level, there are currently two possible ways of deploying PCF as described by the reference architecture:

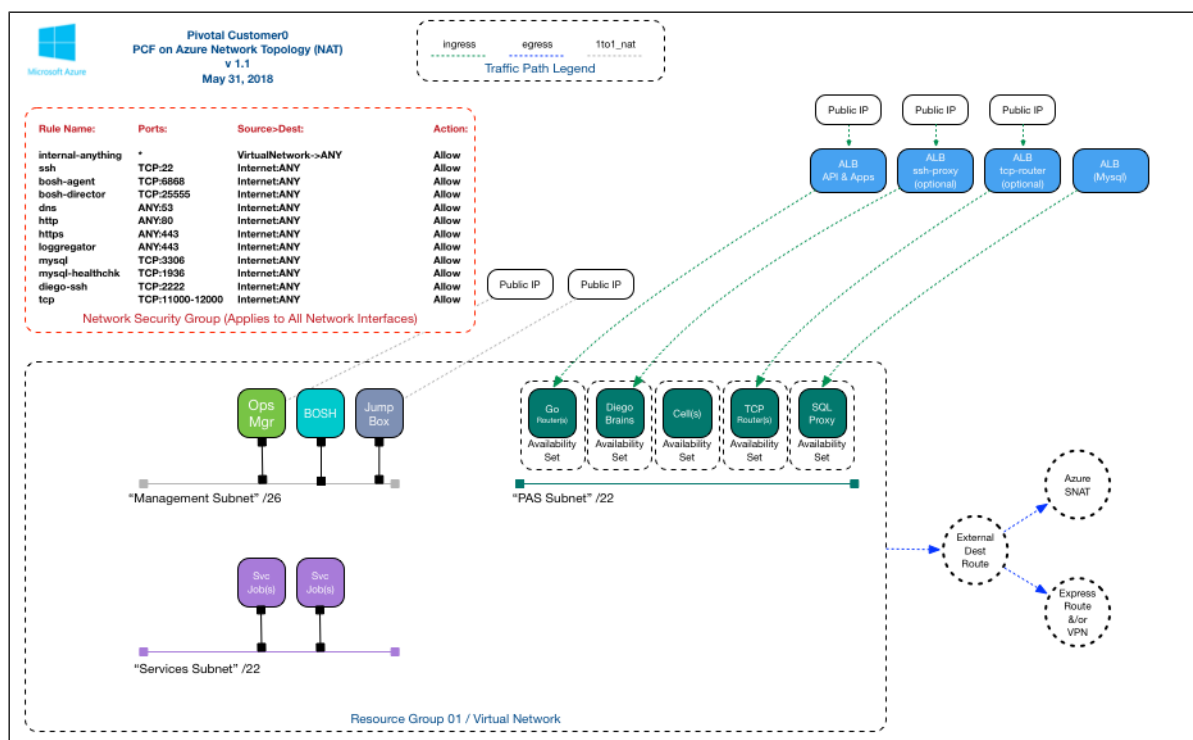

1. Single resource group, or
2. Multiple resource groups.

The first scenario is outlined in [Installing PCF on Azure](#). It models a single PCF deployment in a single Azure Resource Group.

If you require multiple resource groups, refer to the [Multiple Resource Group deployment](#) section of this topic.

Network Layout

This diagram illustrates the network topology of the base reference architecture for PCF on Azure. In this deployment, you expose only a minimal number of public IP addresses and deploy only one resource group.

[View a larger version of this diagram](#)

Network Objects

The following table lists the network objects in PCF on Azure reference architecture.

| Network Object | Notes | Estimated Number |
|------------------------------|---|------------------|
| External Public IP addresses | <p>Use</p> <ol style="list-style-type: none"> 1. global IP address for apps and system access 2. Ops Manager or optional jumpbox. <p>Optionally, you can use a public IP address for the ssh-proxy and tcp-router load balancers.</p> | 1-4 |
| Virtual Network | One per deployment. Azure virtual network objects allow multiple subnets with multiple CIDRs, so a typical deployment of PCF will likely only ever require one Azure Virtual Network object. | 1 |
| Subnets | <p>Separate subnets for</p> <ol style="list-style-type: none"> 1. management (Ops Manager, BOSH Director, Jumpbox), 2. PAS, 3. and services. <p>Using separate subnets allows you to configure different firewall rules due to your needs.</p> | 4 |
| Routes | Routes are typically created by Azure dynamically when subnets are created, but you may need to create additional routes to force outbound communication to dedicated SNAT nodes. These objects are required to deploy PCF without public IP addresses. | 3+ |
| Firewall Rules | Azure firewall rules are collected into a Network Security Group (NSG) and bound to a Virtual Network object and can be created to use IP ranges, subnets, or instance tags to match for source and destination fields in a rule. One NSG can be used for all firewall rules. | 12 |
| Load Balancers | Used to handle requests to Gorouters and infrastructure components. Azure uses 1 or more load balancers. The API and Apps load balancer is required. The TCP Router load balancer used for TCP routing feature and the SSH load balancer that allows SSH access to Diego apps are both optional. In addition, you can use a MySQL load balancer to provide high availability to MySQL. This is also optional. | 1-4 |
| | Optional. Provides a way of accessing different network components. For example, you can configure it with your own | |

Jumpbox permissions and then set it up to access to Pivotal Network to download tiles. Using a jumpbox is particularly useful in IaaSes where Ops Manager does not have a public IP address. In these cases, you can SSH into Ops Manager or any other component through the jumpbox.

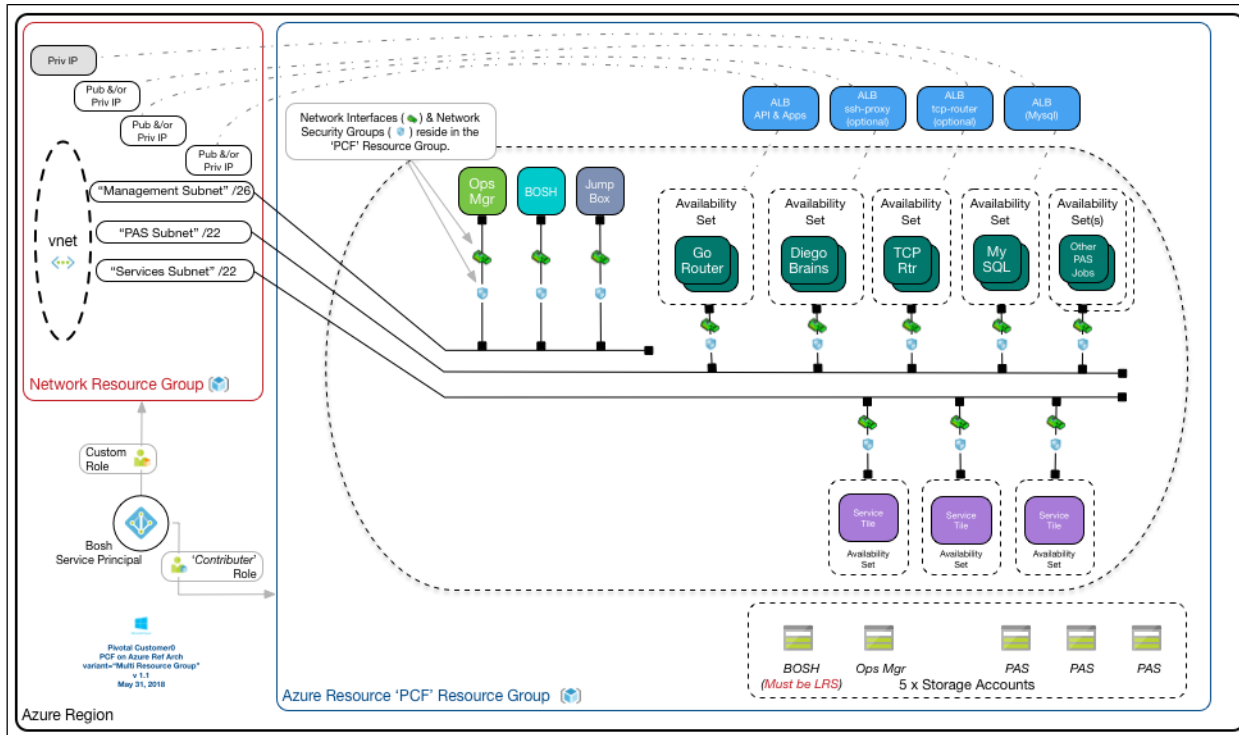

1

Multiple Resource Group Deployment

This diagram illustrates the case where you want to use additional resource groups in your PCF deployment on Azure.

Shared network resources may already exist in an Azure subscription. In this type of deployment, using multiple resource groups allows you to reuse existing resources instead of provisioning new ones.

To use multiple resource groups, you need to provide the BOSH Service Principal with access to the existing network resources.

[View a larger version of this diagram](#).

Multiple Resource Groups Deployment Notes

To deploy PCF on Azure with multiple resource groups, you can define custom roles to grant resource group access to your BOSH Service Principal. For example, you might develop the following:

- Dedicated **Network** Resource Group, limits BOSH Service Principal so that it does not have admin access to network objects.
- Custom Role for BOSH Service Principal, applied to **Network** Resource Group, limits the BOSH Service Principal to minimum read-only access.

```
az role definition create --role-definition
{ \
  "Name": "PCF Network Read Only", \
  "IsCustom": true, \
  "Description": "MVP PCF Read Network Resgroup", \
  "Actions": [ \
    "Microsoft.Network/virtualNetworks/read", \
    "Microsoft.Network/virtualNetworks/subnets/read", \
    "Microsoft.Network/virtualNetworks/subnets/join/action", \
    "Microsoft.Network/networkSecurityGroups/read", \
    "Microsoft.Network/networkSecurityGroups/join/action", \
    "Microsoft.Network/loadBalancers/read", \
    "Microsoft.Network/publicIPAddresses/read", \
    "Microsoft.Network/publicIPAddresses/join/action" \
  ], \
  "NotActions": [], \
  "AssignableScopes": ["/subscriptions/[YOUR_SUBSCRIPTION_ID]" \
  ]
}
```

The actions prefixed with `Microsoft.Network/publicIPAddresses` are only required if using IP addresses.

- Custom Role for BOSH Service Principal, applied to Subscription, allowing the Operator to deploy PCF components

```
az role definition create --role-definition
{ \
  "Name": "PCF Deploy Min Perms", \
  "IsCustom": true, \
  "Description": "MVP PCF Terraform Perms", \
  "Actions": [ \
    "Microsoft.Compute/register/action" \
  ], \
  "NotActions": [], \
  "AssignableScopes": ["/subscriptions/[YOUR_SUBSCRIPTION_ID]" \
  ]
}
```

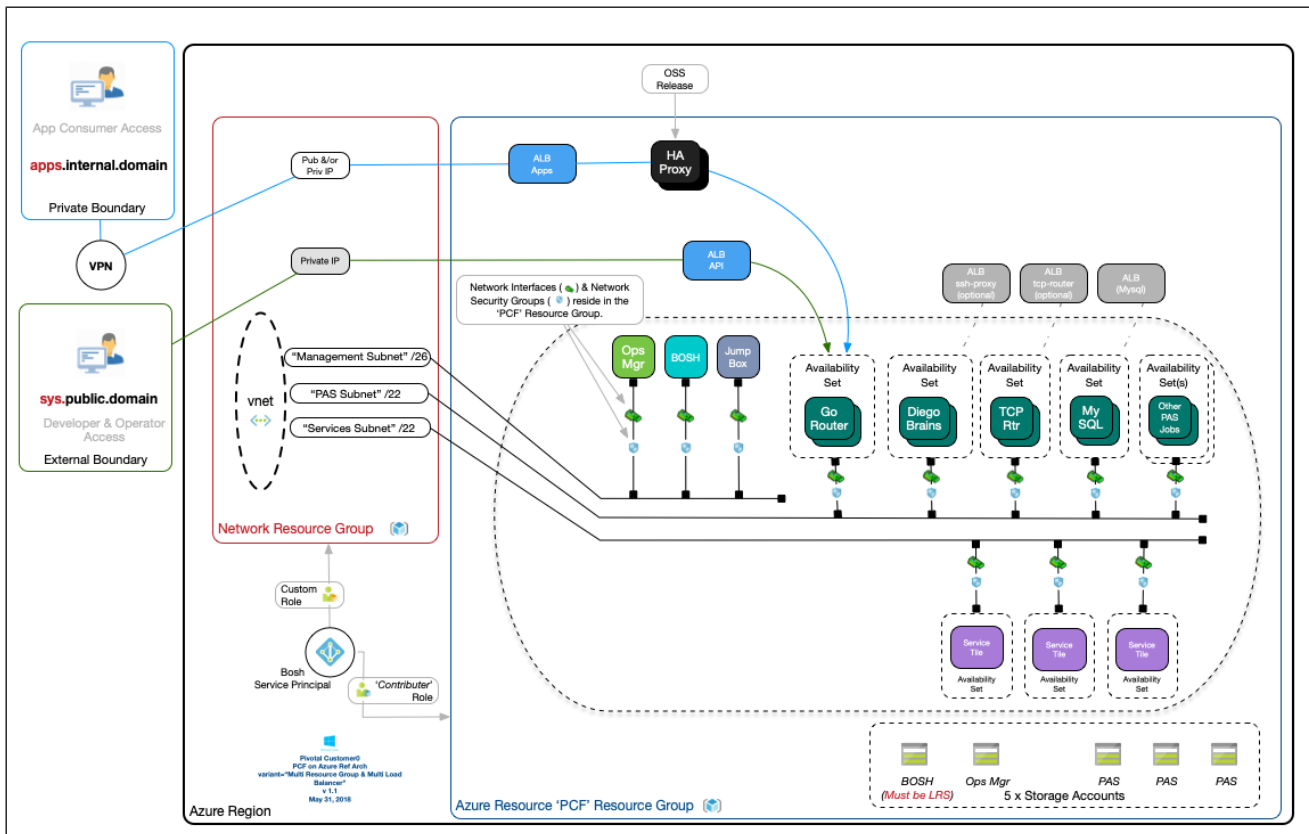

- Custom roles can be assigned to service principals with `az role assignment create --role [ROLE] --assignee [SERVICE_PRINCIPAL_ID]`.

Multiple Resource Group and Multiple Load Balancer Deployment

This diagram illustrates the case where you want to deploy multiple load balancers with your multiple resource group deployment.

The key design points of this deployment are the following:

- Two Azure load balancer (ALBs) to the Gorouter exist. The first ALB is for API access, which utilizes a private IP address. The system domain should resolve to this ALB. The second ALB is for application access, which can either use a public or private IP address. The apps domain should resolve to this ALB.
- Azure does not allow the Gorouters to be members of more than one ALB member pool for the same ports, for example `80` and `443`. This restriction requires an additional reverse proxy to front the Gorouters to allow them to expose traffic on these ports for the system domain.

[View a larger version of this diagram](#)

Log Analytics Integration

[Azure Log Analytics](#) is a service that helps you collect and analyze data generated by resources in your cloud and on-premises environments. The [Microsoft Azure Log Analytics Nozzle for PCF](#) receives logs and metrics from the Loggregator Firehose, filters and resolves the events, and then sends them to Log Analytics, where they appear on unified dashboards and can be correlated with and alerted on other Azure resources.

DNS Delegation

Azure DNS supports DNS delegation, allowing for sub-level domains to be hosted within Azure. This functionality is fully supported within PCF.

Pivotal recommends that you use a sub-zone for your PCF deployment. For example, if your company's domain is `example.com`, your PCF zone in Azure DNS would be `pcf.example.com`.

As Azure DNS does not support recursion, in order to properly configure Azure DNS, create an `NS` record with your registrar which points to the four name servers supplied by your Azure DNS Zone configuration. Once your `NS` records have been created, you can then create the required wildcard `A` records for the PCF application and system domains, as well as any other records desired for your PCF deployments.

You do not need to make any configuration changes in PCF to support Azure DNS.

Azure Blob Storage

Due to limitations in PCF, it is not possible to support a high-availability deployment of the backing NFS store needed for droplets, buildpacks, and other resources. Azure Blob Storage provides fully-redundant hot, cold, or archival storage in either local, regional, or global offerings. It is recommended to use Azure Blob Storage as the external File Storage to provide unlimited scaling and redundancy for high-availability deployments of PCF.

To enable Azure Blob Storage, do the following:

1. Create a Storage Account with the level of redundancy you require. The storage account does not need to be in the same Resource Group as PCF.
2. Create Containers for the buildpacks, droplets, packages, and resources required by PCF.

3. Open Ops Manager.
4. Select **Pivotal Application Services**.
5. Click the **Settings Tab**.
6. Select **File Storage**.
7. Click **External Azure Account**.
8. Enter the Storage Account details.
9. In the Ops Manager main page, apply the changes when you are ready to reconfigure.

 **Note:** There is no direct path to migrate previous objects to Azure Blob Storage. Contact Pivotal Support if you need assistance with this migration.

Load Balancer Migrations

The Azure Load Balancer has two SKUs: Standard and Basic. The Standard SKU Load Balancer is a new load balancer for all TCP and UDP applications with an expanded and more granular feature set over the Basic Load Balancer. Azure's Standard SKU Load Balancer lets you scale your applications and create high availability in environments ranging from small scale deployments to large and complex multi-zone architectures. While the Basic SKU Load Balancer works within the scope of an availability set, a Standard Load Balancer covers an entire virtual network. Pivotal recommends using the Standard SKU Load Balancer instead of the Basic SKU Load Balancer. If you currently use the Basic SKU Load Balancer and wish to migrate to the the Standard SKU, please see the [Migrate Basic SKU Load Balancer to Standard SKU Load Balancer](#) documentation on GitHub.

GCP Reference Architecture

This topic presents two reference architectures for installing Pivotal Cloud Foundry (PCF) on Google Cloud Platform (GCP): on a [shared virtual private cloud](#) (VPC) and on a [single-project VPC](#). This topic also outlines multiple networking variants for VPC deployment. The architectures are validated for production-grade PCF deployments using multiple AZs.

See [PCF on GCP Requirements](#) for general requirements for running PCF and specific requirements for running PCF on GCP.

PCF Reference Architectures

A PCF reference architecture describes a proven approach for deploying PCF on a specific IaaS, such as GCP.

A PCF reference architecture must meet the following requirements:

- Be secure
- Be publicly-accessible
- Include common PCF-managed services such as MySQL, RabbitMQ, and Spring Cloud Services
- Be able to host at least 100 app instances

Pivotal provides reference architectures to help you determine the best configuration for your PCF deployment.

Shared vs Single-Project VPCs

A [shared VPC](#) installation is harder to configure than a PCF deployment on a single-project VPC, because the required account privileges and resource allocations are more granular and complex. But the shared VPC architecture allows network assets to be centrally located, which simplifies auditing and security. Pivotal recommends the shared VPC model for:

- Deployments with deep auditing and security requirements
- When networks hosting the foundation need to connect back to an internal network via VPN or interconnect

A [single-project VPC](#) lets the platform architect give PCF full access to the VPC and its resources, which makes configuration easier. Pivotal recommends single-project VPC architecture for:

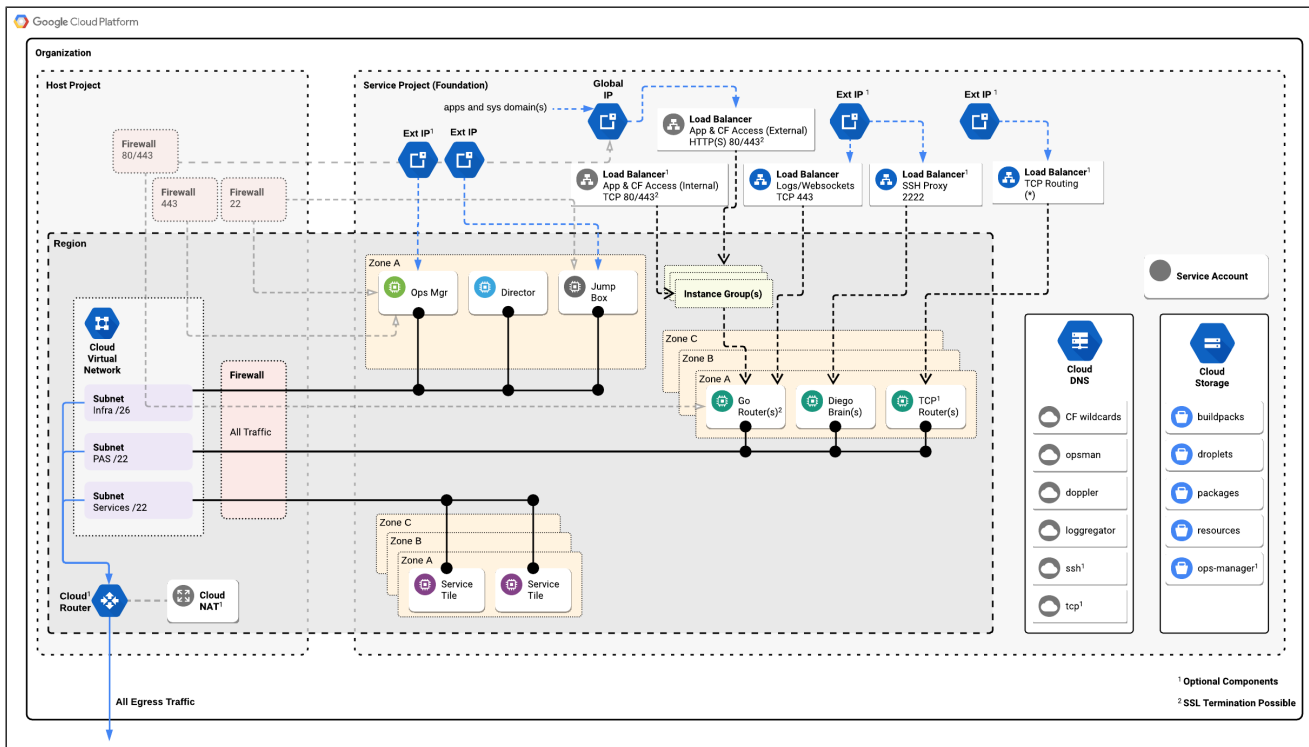

- Standalone deployments that do not connect to an internal network
- Test and experimental deployments, and for projects which do not belong to an organization

Shared VPC GCP Reference Architecture

The following diagram provides an overview of a reference architecture deployment of PCF on a shared VPC on GCP. This architecture requires an organization on the VPC that contains a host project and a service project.

For more information about shared VPCs on GCP, see [Shared VPC Overview](#) in the Google Cloud documentation.

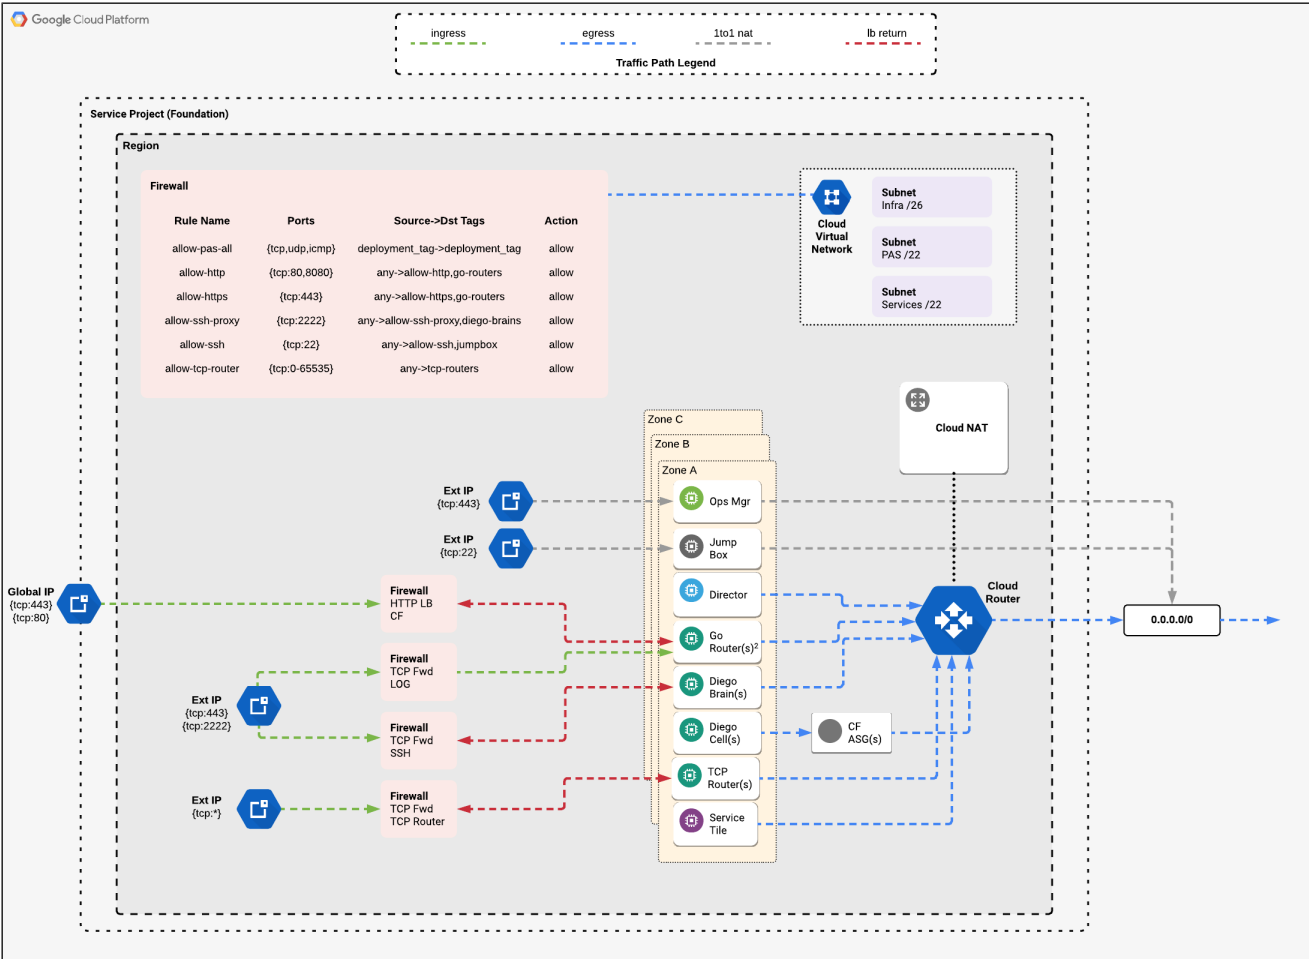

For more information about how this architecture divides resources between projects, see [Host / Service Architecture](#).

[View a larger version of this diagram.](#)

NAT Network Topology

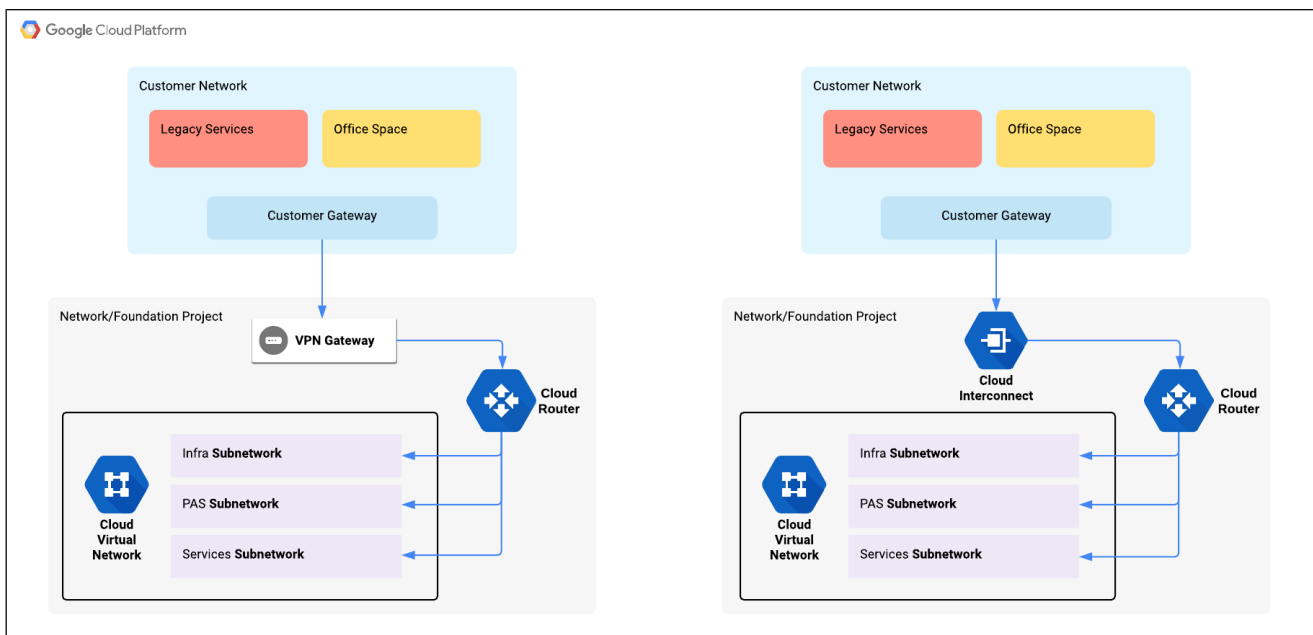

To expose a minimal number of public IP addresses, set up your NAT as shown in this diagram.

[View a larger version of this diagram.](#)

Cloud Interconnect

To speed communication between data centers, use Google Cloud Interconnect as shown in this diagram.

[View a larger version of this diagram.](#)

Host / Service Architecture

GCP allocates resources using a hierarchy that centers around projects. To create a VPC, architects define a *host project* that allocates network resources for the VPC, such as address space and firewall rules. Then they can define one or more *service projects* to run within the VPC, which share the network resources allocated by the host project and include their own non-network resources, such as VMs and storage buckets.

To install PCF in a shared VPC on GCP, you create a host project for the VPC and a service project dedicated to running PCF.

Host Project Resources

The host project centrally manages the following shared VPC network resources for PCF:

- Infra subnet (Ops Manager and BOSH Director)
- PAS subnet
- Services subnet
- Isolation Segments
- Firewall rules
- NAT instances and gateway
- VPN/interconnect
- Routes, e.g. egress internet through NAT or egress on-premises through VPN

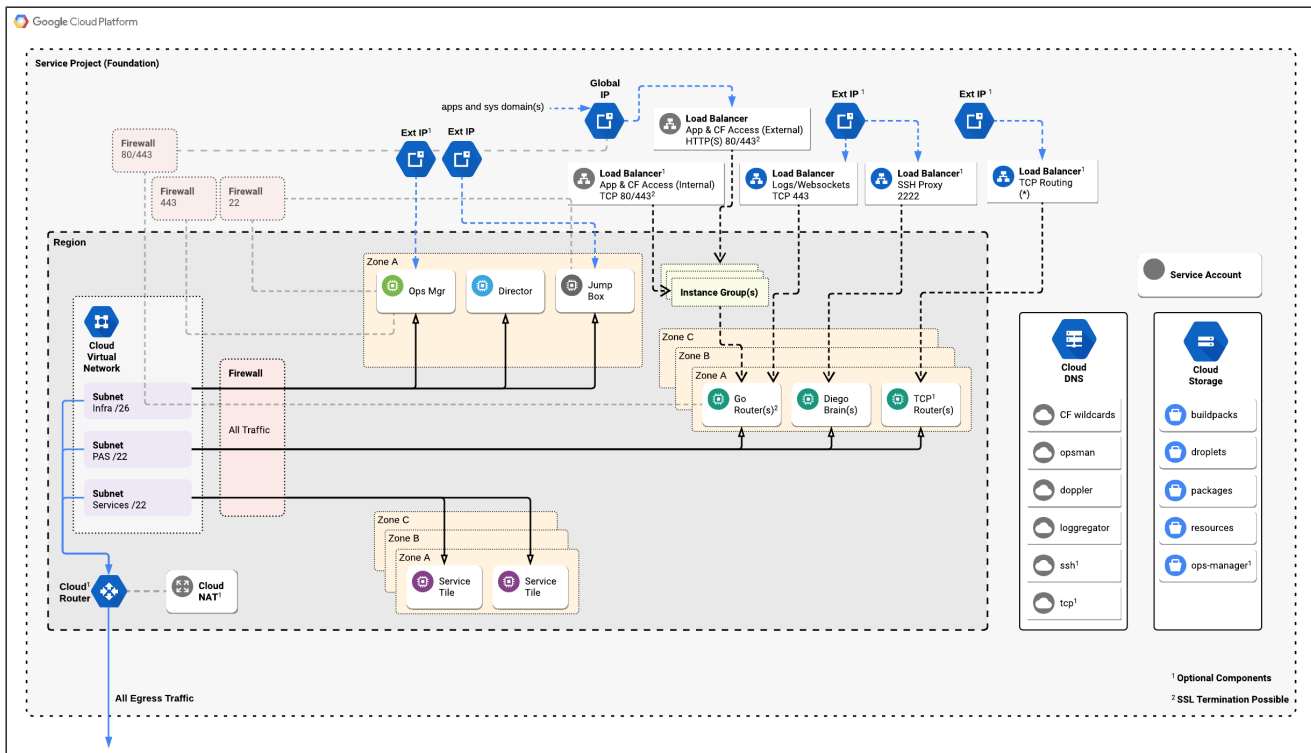

Service Project Resources

The PCF service project manages the following resources:

- Google Cloud Compute instances (VMs)
 - BOSH
 - Ops Manager
 - VMs deployed by BOSH, such as PCF and service components
- Google Cloud Storage buckets, for blobstore
 - BOSH Director
 - Resources
 - Buildpacks
 - Droplets
 - Packages
- Service account and a service account key for PCF to access the storage buckets
- A service account for PCF
- Load Balancers
- Google Cloud SQL instances, if using external databases

Single-Project VPC Base GCP Reference Architecture

The following diagram provides an overview of a reference architecture deployment of PCF on a single-project [VPC](#) on GCP.

[View a larger version of this diagram.](#)

Base Reference Architecture Components

The following table lists the components that are part of a reference architecture deployment with three availability zones.

| Component | Reference Architecture Notes |
|-----------------------------|---|
| Domains & DNS | CF Domain Zones and routes in use by the reference architecture include: domains for *.apps and *.system (required), a route for Ops Manager (required), a route for doppler (required), a route for Loggregator (required), a route for ssh access to app containers (optional) and a route for TCP routing to apps (optional). Reference architecture uses GCP Cloud DNS as the DNS provider. |
| Ops Manager | Deployed on the infrastructure subnet and accessible by FQDN or through an optional jumpbox. |
| BOSH Director | Deployed on the infrastructure subnet. |
| Gorouters | Accessed through the HTTP and TCP WebSockets load balancers. Deployed on the Pivotal Application Service (PAS) subnet, one job per availability zone. |
| Diego Brains | Required. However, the SSH container access functionality is optional and enabled through the SSH Proxy load balancer. Deployed on the PAS subnet, one job per availability zone. |
| TCP Routers | Optional feature for TCP routing. Deployed on the PAS subnet, one job per availability zone. |
| CF Database | Reference architecture uses GCP Cloud SQL rather than internal databases. Configure your database with a strong password and limit access only to components that require database access. |
| CF Blob Storage and Buckets | For buildpacks, droplets, packages and resources. Reference architecture uses Google Cloud Storage rather than internal file storage. |
| Services | Deployed on the PCF managed services subnet. Each service is deployed to each availability zone. |

Alternative GCP Network Layouts for PCF

This section describes the possible network layouts for PCF deployments as covered by the reference architecture of PCF on GCP.

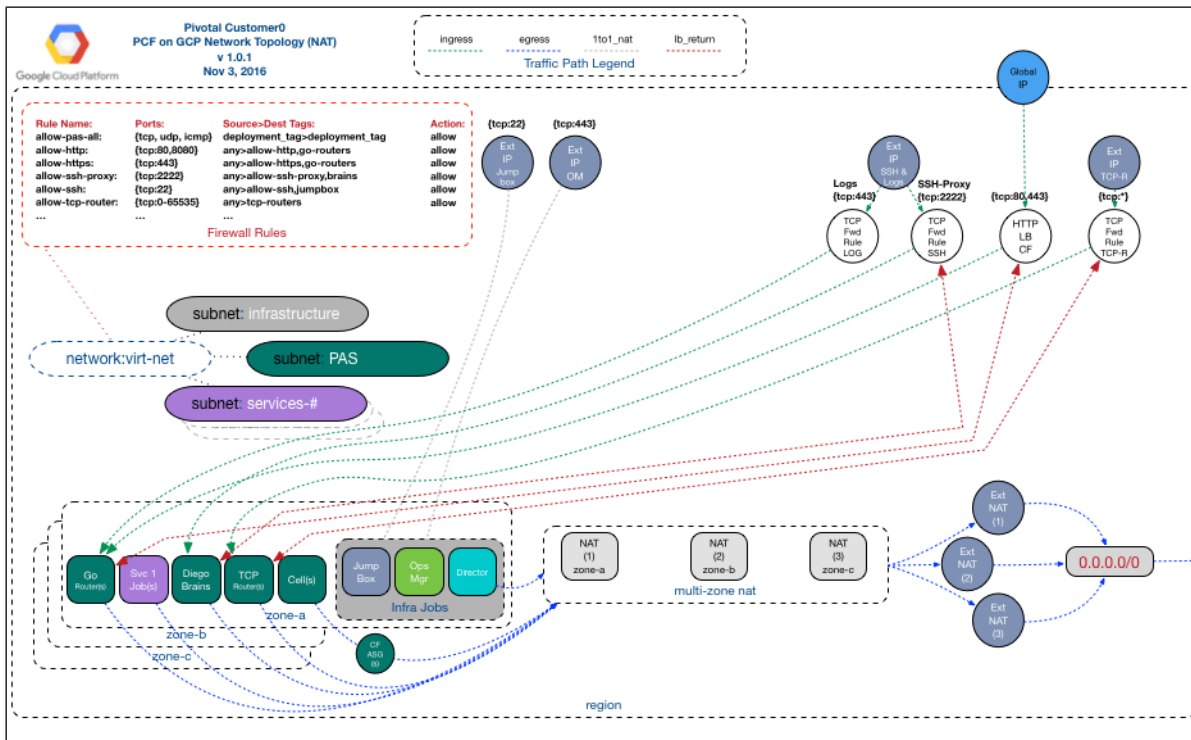

At a high level, there are currently two possible ways of granting public Internet access to PCF as described by the reference architecture:

- NAT provides connectivity from PCF internals to the public Internet.
 - The instructions for [Installing PCF on GCP Manually](#) use this method.
- Every PCF VM receives its own public IP address (no NAT).
 - The instructions for [Installing PCF on GCP using Terraform](#) use this method.

However, if you require NAT, you may refer to the following section.

NAT-based Solution

This diagram illustrates the case where you want to expose only a minimal number of public IP addresses.

[View a larger version of this diagram](#)

Public IP addresses Solution

If you prefer not to use a NAT solution, you can configure PCF on GCP to assign public IP addresses for all components. This type of deployment may be more performant since most of the network traffic between Cloud Foundry components are routed through the front end load balancer and the Gorouter.

Network Objects

The following table lists the network objects expected for each type of reference architecture deployment with three availability zones (assumes you are using NAT).

| Network Object | Notes | Minimum Number: NAT-based | Minimum Number: Public IP Addresses |
|----------------|---|---------------------------|-------------------------------------|
| External IPs | For a NAT solution, use global IP address for apps and system access, and Ops Manager or optional jumpbox | 2 | 30+ |
| NAT | One NAT per availability zone. | 3 | 0 |
| Network | One per deployment. GCP Network objects allow multiple subnets with multiple CIDRs, so a typical deployment of PCF will likely only ever require one GCP Network object | 1 | 1 |
| | Separate subnets for infrastructure (Ops Manager, BOSH Director, Jumpbox), PAS, and services. Using separate | | |

| | | | |
|------------------------------|---|----------------------------------|--|
| Subnets | subnets allows you to configure different firewall rules due to your needs. | Minimum Number: NAT-based | Minimum Number: Public IP Addresses |
| Network Object Routes | Routes are typically created by GCP dynamically when subnets are created, but you may need to create additional routes to force outbound communication to dedicated SNAT nodes. These objects are required to deploy PCF without public IP addresses. | | |
| Firewall Rules | GCP firewall rules are bound to a Network object and can be created to use IP ranges, subnets, or instance tags to match for source & destination fields in a rule. The preferred method use in the reference architecture deployment is instance tags. | 6+ | 6+ |
| Load balancers | Used to handle requests to Gorouters and infrastructure components. GCP uses two or more load balancers. The HTTP load balancer and TCP WebSockets load balancer are both required. The TCP Router load balancer used for TCP routing feature and the SSH load balancer that allows SSH access to Diego apps are both optional. The HTTP load balancer provides SSL termination. | 2+ | 2+ |
| Jumpbox | Optional. Provides a way of accessing different network components. For example, you can configure it with your own permissions and then set it up to access to Pivotal Network to download tiles. Using a jumpbox is particularly useful in IaaS where Ops Manager does not have a public IP address. In these cases, you can SSH into Ops Manager or any other component through the jumpbox. | (1) | (1) |

Network Communication in GCP Deployments

This section provides more background on the reasons behind certain network configuration decisions, specifically for the Gorouter.

Load Balancer to Gorouter Communications and TLS Termination

In a PCF on GCP deployment, the Gorouter receives two types of traffic:

1. Unencrypted HTTP traffic on port 80 that is decrypted by the HTTP(S) load balancer.
2. Encrypted secure web socket traffic on port 443 that is passed through the TCP WebSockets load balancer.

In a PCF on GCP deployment, the Gorouter receives two types of traffic:

1. Unencrypted HTTP traffic on port 80 that is decrypted by the HTTP(S) load balancer.
2. Encrypted secure web socket traffic on port 443 that is passed through the TCP WebSockets load balancer.

TLS is terminated for HTTPS on the HTTP load balancer and is terminated for WebSockets (WSS) traffic on the Gorouter.

PCF deployments on GCP use two load balancers to handle Gorouter traffic because HTTP load balancers currently do not support WebSockets.

ICMP

GCP routers do not respond to ICMP; therefore, Pivotal recommends disabling ICMP checks in [BOSH Director network configuration](#).

OpenStack Reference Architecture

This guide presents a reference architecture for Pivotal Cloud Foundry (PCF) on OpenStack. This architecture is valid for most production-grade PCF deployments in a single project using three availability zones (AZs).

See [OpenStack on PCF Requirements](#) for general requirements for running PCF and specific requirements for running PCF on OpenStack.

PCF Reference Architectures

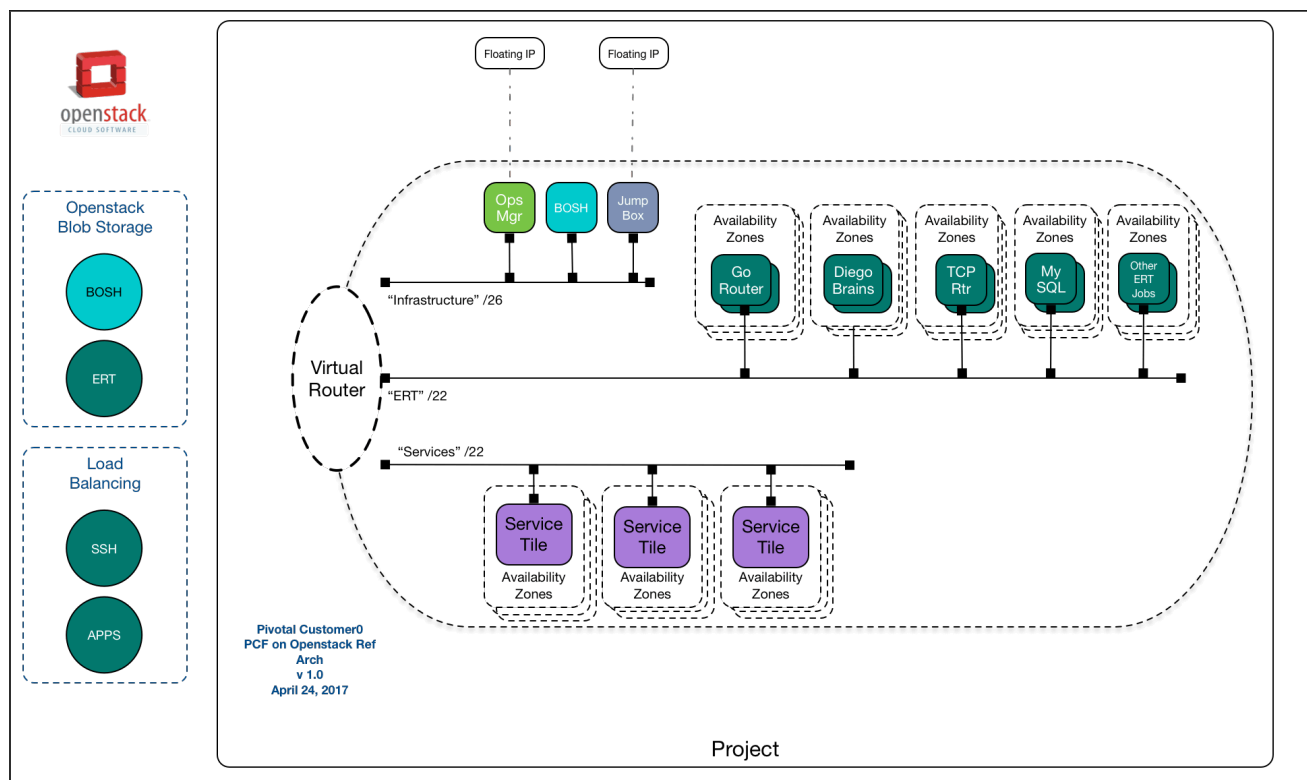

A PCF reference architecture describes a proven approach for deploying Pivotal Cloud Foundry on a specific IaaS, such as OpenStack, that meets the following requirements:

- Secure
- Publicly-accessible
- Includes common PCF-managed services such as MySQL, RabbitMQ, and Spring Cloud Services
- Can host at least 100 app instances, or far more

Pivotal provides reference architectures to help you determine the best configuration for your PCF deployment.

Base OpenStack Reference Architecture

The following diagram provides an overview of a reference architecture deployment of PCF on OpenStack using three AZs.

[View a larger version of this diagram.](#)

Base Reference Architecture Components

The following table lists the components that are part of a base reference architecture deployment on OpenStack with three AZs.

| Component | Reference Architecture Notes |
|-----------|--|
| | CF Domain zones and routes in use by the reference architecture include: |

| | |
|----------------------------------|--|
| Domains & DNS | <ul style="list-style-type: none"> • zones for *.apps and *.sys (required) • a route for Ops Manager (required) • a route for Doppler (required) • a route for Loggregator (required) • a route for ssh access to app containers (optional) • a route for tcp access to tcp routers (optional) |
| Ops Manager | Deployed on the infrastructure network and accessible by FQDN or through an optional jumpbox. |
| BOSH Director | Deployed on the infrastructure network. |
| Application Load Balancer | Required. Load balancer that handles incoming HTTP, HTTPS, TCP, and SSL traffic and forwards them to the Gorouters. Load balancers are outside the scope of this document. |
| SSH Load Balancer | Optional. Load balancer that provides SSH access to application containers for developers. Load balancers are outside the scope of this document. |
| Gorouters | Accessed through the Application Load Balancer. Deployed on the Pivotal Application Service (PAS) network, one per AZ. |
| Diego Brains | This component is required. However, the SSH container access functionality is optional and enabled through the SSH Load Balancers. Deployed on the PAS network, one per AZ. |
| TCP Routers | Optional feature for TCP routing. Deployed on the PAS network, one per AZ. |
| CF Database | Reference architecture uses internal MySQL. |
| Storage Buckets | Reference architecture uses customer provided blobstore. Buckets are needed for BOSH and PAS. |
| Service Tiles | Deployed on the services network. |
| Service Accounts | <p>Two service accounts are recommended: one for OpenStack “paving,” and the other for Ops Manager and BOSH. Consult the following list:</p> <ul style="list-style-type: none"> • Admin Account: Concourse will use this account to provision required OpenStack resources as well as a Keystone service account. • Keystone Service Account: This service account will be automatically provisioned with restricted access only to resources needed by PCF. |
| OpenStack Quota | The default compute quota on a new OpenStack subscription is typically not enough to host a multi-AZ deployment. The recommended quota for instances is 100. Your OpenStack network quotas may also need to be increased. |

OpenStack Objects

The following table lists the network objects in this reference architecture.

| Network Object | Notes | Estimated Number |
|------------------------------|--|------------------|
| Floating IP addresses | Two per deployment. One assigned to Ops Manager, the other to your jumpbox. | 2 |
| Project | One per deployment. A PCF deployment exists within a single project and a single OpenStack region, but should distribute PCF jobs and instances across three OpenStack AZs to ensure a high degree of availability. | 1 |
| Networks | <p>The reference architecture requires the following Tenant Networks:</p> <ul style="list-style-type: none"> • 1 x (/24) Infrastructure (Ops Manager, BOSH Director, Jumpbox). • 1 x (/20) PAS (Gorouters, Diego Cells, Cloud Controllers, etc.). • 1 x (/20) Services (RabbitMQ, MySQL, Spring Cloud Services, etc.) • 1 x (/24) On-demand services (Various.) <p>An Internet-facing network is also required:</p> <ul style="list-style-type: none"> • 1 x Public network. <p> Note: In many cases, the public network is an “under the cloud” network that is shared across projects.</p> | 5 |
| | This reference architecture requires one router attached to all networks: | |

| Routers | <ul style="list-style-type: none">VirtualRouter: This router table enables the ingress/egress routes from/to Internet to the project networks and provides sNAT services. | 1 | | | | | | | | | | | | | | | | | | | | |
|-----------------|--|----------------|---------------|--|----------|-------------|----------|-------------|-----------|------|------------------------------|----------|-------------|-----------|-------|--|-------|------------------|----------|-----|--|---|
| Security Groups | <p>The reference architecture requires one Security Groups. The following table describes the Security Group ingress rules:</p> <table><tr><th>Security Group</th><th>Port</th><th>From CIDR</th><th>Protocol</th><th>Description</th></tr><tr><td>OpsMgrSG</td><td>22</td><td>0.0.0.0/0</td><td>TCP</td><td>Ops Manager SSH access</td></tr><tr><td>OpsMgrSG</td><td>443</td><td>0.0.0.0/0</td><td>TCP</td><td>Ops Manager HTTP access</td></tr><tr><td>VmsSG</td><td>ALL</td><td>VPC_CIDR</td><td>ALL</td><td>Open up connections among BOSH-deployed VMs</td></tr></table> <p>Additional security groups may be needed which are specific to your chosen load balancing solution.</p> | Security Group | Port | From CIDR | Protocol | Description | OpsMgrSG | 22 | 0.0.0.0/0 | TCP | Ops Manager SSH access | OpsMgrSG | 443 | 0.0.0.0/0 | TCP | Ops Manager HTTP access | VmsSG | ALL | VPC_CIDR | ALL | Open up connections among BOSH-deployed VMs | 5 |
| Security Group | Port | From CIDR | Protocol | Description | | | | | | | | | | | | | | | | | | |
| OpsMgrSG | 22 | 0.0.0.0/0 | TCP | Ops Manager SSH access | | | | | | | | | | | | | | | | | | |
| OpsMgrSG | 443 | 0.0.0.0/0 | TCP | Ops Manager HTTP access | | | | | | | | | | | | | | | | | | |
| VmsSG | ALL | VPC_CIDR | ALL | Open up connections among BOSH-deployed VMs | | | | | | | | | | | | | | | | | | |
| Load Balancers | <p>PCF on OpenStack requires a load balancer, which can be configured with multiple listeners to forward HTTP/HTTPS/TCP traffic. Two load balancers are recommended: one to forward the traffic to the Gorouters, <code>AppsLB</code> , the other to forward the traffic to the Diego Brain SSH proxy, <code>SSHLB</code> .</p> <p>The following table describes the required listeners for each load balancer:</p> <table><tr><th>Name</th><th>Instance/Port</th><th>LB Port</th><th>Protocol</th><th>Description</th></tr><tr><td>AppsLB</td><td>gorouter/80</td><td>80</td><td>HTTP</td><td>Forward traffic to Gorouters</td></tr><tr><td>AppsLB</td><td>gorouter/80</td><td>443</td><td>HTTPS</td><td>SSL termination and forward traffic to Gorouters</td></tr><tr><td>SSHLB</td><td>diego-brain/2222</td><td>2222</td><td>TCP</td><td>Forward traffic to Diego Brain for container SSH connections</td></tr></table> <p>Each load balancer needs a check to validate the health of the back-end instances:</p> <ul style="list-style-type: none"><code>AppsLB</code> checks the health on Gorouter port 80 with TCP<code>SSHLB</code> checks the health on Diego Brain port 2222 with TCP <div> Note: In many cases, the load balancers are provided as an “under the cloud” service that is shared across projects.</div> | Name | Instance/Port | LB Port | Protocol | Description | AppsLB | gorouter/80 | 80 | HTTP | Forward traffic to Gorouters | AppsLB | gorouter/80 | 443 | HTTPS | SSL termination and forward traffic to Gorouters | SSHLB | diego-brain/2222 | 2222 | TCP | Forward traffic to Diego Brain for container SSH connections | 2 |
| Name | Instance/Port | LB Port | Protocol | Description | | | | | | | | | | | | | | | | | | |
| AppsLB | gorouter/80 | 80 | HTTP | Forward traffic to Gorouters | | | | | | | | | | | | | | | | | | |
| AppsLB | gorouter/80 | 443 | HTTPS | SSL termination and forward traffic to Gorouters | | | | | | | | | | | | | | | | | | |
| SSHLB | diego-brain/2222 | 2222 | TCP | Forward traffic to Diego Brain for container SSH connections | | | | | | | | | | | | | | | | | | |
| Jumpbox | Optional. Provides a way of accessing different network components. For example, you can configure it with your own permissions and then set it up to access to Pivotal Network to download tiles. Using a jumpbox is particularly useful in IaaS where Ops Manager does not have a public IP address. In these cases, you can SSH into Ops Manager or any other component through the jumpbox. | 1 | | | | | | | | | | | | | | | | | | | | |

vSphere Reference Architecture

This guide provides reference architectures for Pivotal Cloud Foundry (PCF), including Pivotal Application Service (PAS) and Pivotal Container Service (PKS), on vSphere.

Overview

Pivotal validates the reference architectures described in this topic against multiple production-grade usage scenarios.

This document does not replace the installation instructions provided in the [PCF on vSphere Requirements](#) topic. Instead, it gives examples of how to apply those instructions to real-world production environments.

| PCF Products Validated | Version |
|--|----------------|
| vSphere | 6.5 |
| VMware NSX-T | 2.2 |
| Pivotal Cloud Foundry Operations Manager | 2.2 or later |
| PAS | 2.2 or later |
| PKS | 1.1.5 or later |

Base vSphere Reference Architecture

This reference architecture includes VMware vSphere and NSX-T, a software-defined network virtualization platform that runs on VMware ESXi virtual hosts.

The reference architecture supports capacity growth at the vSphere and PCF levels as well as installation security through the NSX-T firewall. It allocates a minimum of three servers to each cluster and spreads PCF components across three clusters for high availability (HA). For information about HA in PCF, see [High Availability in Cloud Foundry](#).

To use all features listed in this topic for your PAS installation, you must have **Advanced** or above licensing from VMware for NSX-T. For PKS, the required licensing is included by default.

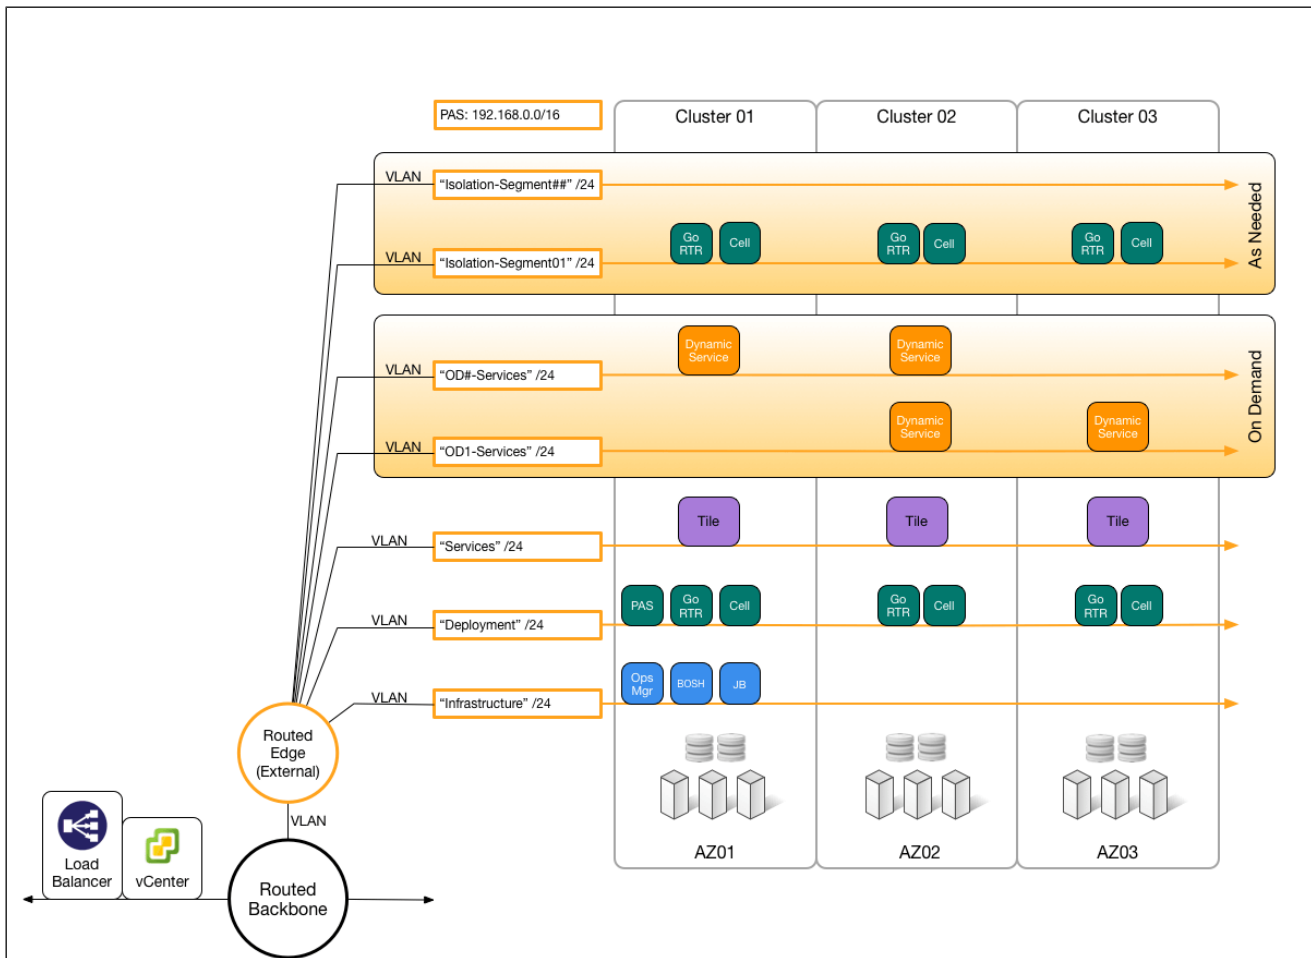

If you want to deploy PCF without NSX-T, see [vSphere Reference Architecture](#), which includes NSX-V design considerations.

Non-SDN Deployments

This section provides information about VLAN and container-to-container networking considerations for PCF deployments that do not use software-defined networking (SDN).

VLAN Considerations

Without an SDN environment, you draw network address space and broadcast domains from the greater data center pool. For this approach, you need to deploy PAS and PKS in a particular alignment.

[View a larger version of this diagram](#)

When designing a non-SDN environment, ensure that VLANs and address space for PAS and PKS do not overlap. In addition, note that non-SDN PCF environments have the following characteristics:

- Load balancing is performed external to the PCF installation.
- Client SSL termination must happen either at the load balancer or Gorouters, or both. Ensure your certificates can accomplish this.
- Firewall layer is accomplished external to the PCF installation.

Container-to-Container Networking and CNI Considerations

Changing your container-to-container networking strategy after deployment is possible. However, with NSX-T, you need both the VMware NSX-T Container Plug-In for PCF tile and NSX-T infrastructure. For information about deploying PAS on vSphere with NSX-T internal networking using the VMware NSX-T Container Plug-In for PCF tile, see [Deploying PAS with NSX-T Networking](#).

Migrating from a non-SDN environment to an SDN-enabled solution is possible but best considered as a greenfield deployment. Inserting an SDN layer under an active PCF installation is disruptive.

PAS Without SDN

You can use PAS without an SDN overlay. For more information, see [PCF on vSphere Requirements](#).

PKS Without SDN

NSX-T SDN is included in PKS by default, along with the associated licensing. Alternatively, you can use a built-in network stack, Flannel, which handles container networking.

If you want to deploy PKS without NSX-T, select **Flannel** as your container networking interface in the **Networking** pane of the PKS tile. For information

about configuring your container networking interface, see the [Networking](#) section in *Installing PKS on vSphere*.

In addition, you must define networks for deploying PKS and PKS-provisioned Kubernetes clusters. For information about defining these networks in Ops Manager, see the [Create Networks Page](#) section in *Configuring Ops Manager on vSphere*.

SDN-Enabled Deployments With NSX-T

This section provides information about network requirements, routing, and load balancing for PAS and PKS deployments that use SDN.

Network Requirements for PAS

PAS requires a number of statically defined networks to host the main components it is composed of. For the Tenant side of an NSX-T deployment, a series of non-routable address banks that the NSX-T routers will manage is defined as follows:

 **Note:** These static networks have a smaller host address space assigned than reference designs for PCF v1.xx.

- Infrastructure: 192.168.1.0/24
- Deployment: 192.168.2.0/24
- Services: 192.168.3.0/24
The Services network can be used with other Ops Manager tiles that you install in addition to PAS. Some of these tiles may require on-demand network capacity. Pivotal recommends that you consider adding a network per tile that needs on-demand resources and pair them up in the tile's configuration. For more information, see *OD-Services#* below.
- OD-Services#: 192.168.4.0 - 192.168.9.0 in /24 segments
For example, the Redis for PCF tile asks for Network and Services Network. The first one is for placing the broker, and the second one is for deploying worker VMs to support the service. In this scenario, you can deploy a new network OD-Services1 and instruct Redis for PCF to use the Services network for the broker and the OD-Services1 network for the workers. The next tile can use the Services network for the broker and a new OD-Services2 network for workers and so on.
- Isolation Segments: 192.168.10.0 - 192.168.63.0 in /24 segments
Isolation segments can be added to an existing PAS installation. This range of address space is used when you add one or more segments. A /24-network in this range should be deployed for each new isolation segment. The capacity of this address bank is sufficient for more than 50 isolation segments, each having more than 250 VMs.
- PAS Dynamic Orgs: 192.168.128.0/17 = 128 orgs/foundation
Dynamically assigned Org networks are attached to automatically generated NSX-T Tier-1 routers. Instead of defining these networks in Ops Manager, the operator provides a non-overlapping block of address space. This is configurable in the NCP pane of the VMware NSX-T Container Plug-In for PCF tile in Ops Manager. Every Org receives a new /24 network.

This reference uses a pattern that follows previous references. However, all networks now break on the /24 boundary, and the network octet is numerically sequential (1-2-3).

Network Requirements for PKS

When deploying PKS through Ops Manager, you must allocate a block of address space for dynamic networks that PKS will deploy per namespace.

Network requirements for PKS are as follows:

- PKS Clusters: 172.24.0.0/14
- PKS Pods: 172.28.0.0/14

Summary

The complete addressing strategy for both PAS and PKS is as follows:

- Infrastructure: 192.168.1.0/24
- Deployment: 192.168.2.0/24
- Services: 192.168.3.0/24
- OD-Services#: 192.168.4.0 - 192.168.9.0 in /24 segments

- Isolation Segments: 192.168.10.0 - 192.168.63.0 in /24 segments
- Undefined: 192.168.64.0 - 192.168.127.0
- PAS Dynamic Orgs: 192.168.128.0/17
- PKS Clusters: 172.24.0.0/14
- PKS Pods: 172.28.0.0/14

Network Requirements for External Routing

Routable external IPs on the provider side, for example, for NATs, PAS orgs, and load balancers, are assigned to the T0 router, which is located in front of the PCF installation. There are two approaches to assigning address space blocks to this job:

- Without PKS or with PKS Ingress: The T0 router needs some routable address space to advertise on the BGP network with its peers. Select a network range with ample address space that can be split into two logical jobs: one job is advertised as a route for traffic, and the other job is for aligning T0 DNATs and SNATs, load balancers, and other jobs. Unlike with NSX-V, SNATs consume much more address space than before.
- With PKS No Ingress: Compared to the approach above, this approach has much higher address space consumption for load balancer VIPs. Therefore, allow for 4x the address space because Kubernetes service types allocate addresses frequently.

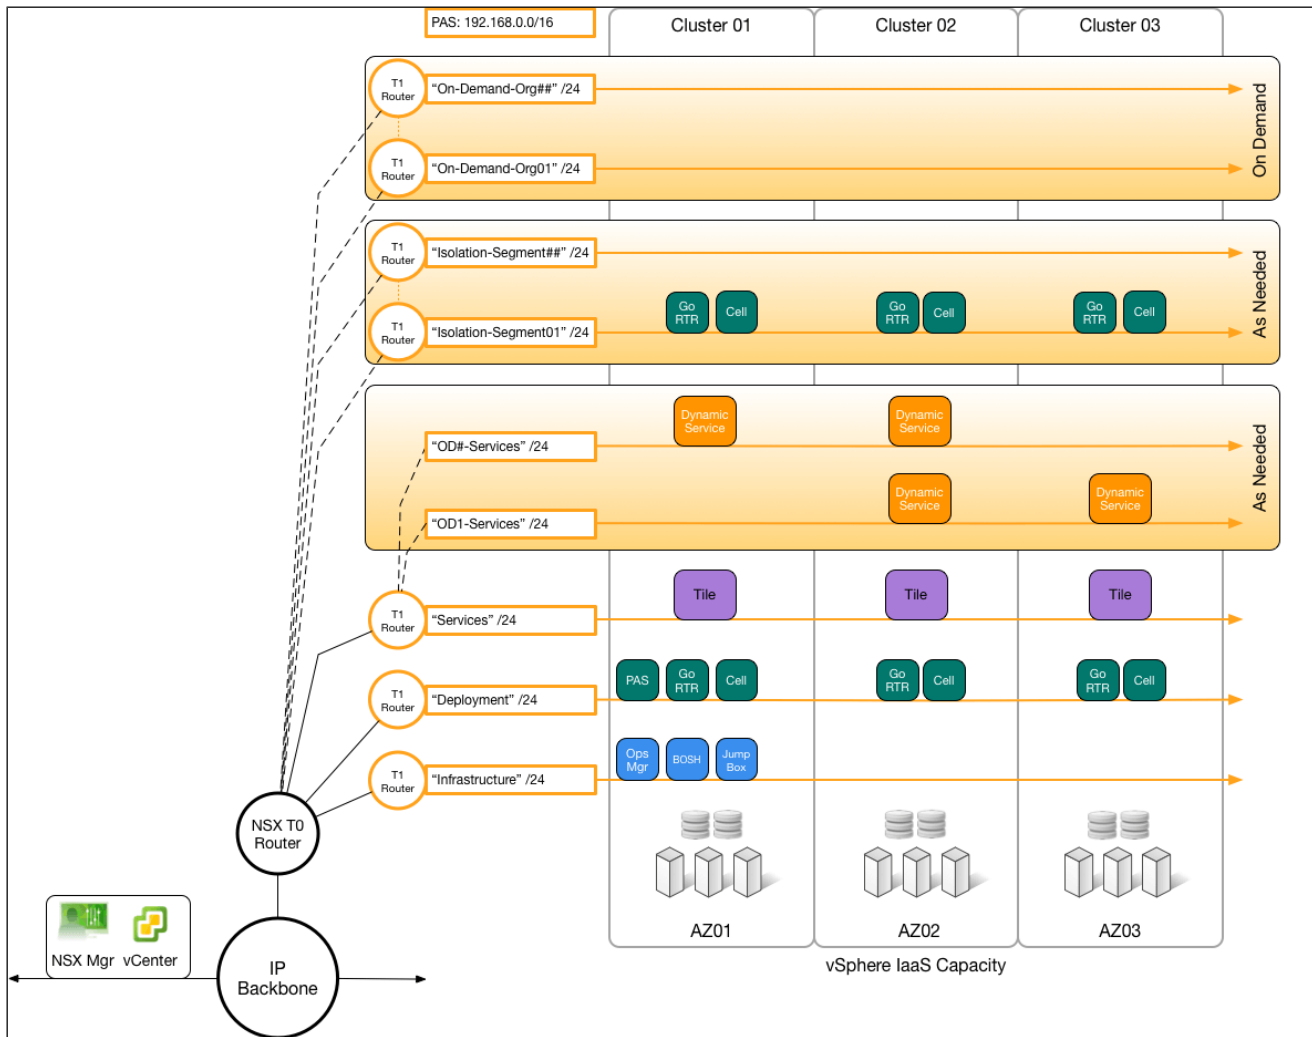

Provider routable address space is /25 or /23 for PKS No Ingress.

NSX-T handles the routing between a T0 router and any T1 routers associated with it.

PAS with NSX-T

Expanding PAS with SDN features is best considered as a greenfield effort. Inserting an SDN layer under a working PAS installation is non-trivial and likely triggers a rebuild. NSX-T constructs that can be used by PAS include the following:

- Logical networks, encapsulated broadcast domains
- VLAN exhaustion avoidance through the use of logical networks
- Routing services and NAT/SNAT to network fence the PCF installation
- Load balancing services to pool systems such as Gorouters
- SSL termination at the load balancer
- Distributed routing and firewall services at the hypervisor

[View a larger version of this diagram](#)

The VMware NSX-T Container Plug-In for PCF tile, which provides a container networking stack instead of the built-in Silk solution, interlocks with NSX-T already deployed on the IaaS. This tile cannot be used unless NSX-T has already been established on the IaaS. These technologies cannot be retrofitted into an established PKS or PAS installation.

To deploy PAS with NSX-T, you need to provide the following in the VMware NSX-T Container Plug-In for PCF tile:

- NSX Manager host
- Username and password
- NSX Manager CA certificate
- PAS foundation name that must match the tag added to T0 router, external NAT pool, and IP block
- Subnet prefix, which controls the size of each org and defaults to /24, that is, 254 addresses

In addition, you must select **Enable SNAT for Container Networks** in the tile. For more information about configuring PAS with NSX-T networking, see [Deploying PAS with NSX-T Networking](#).

Each new job, such as an isolation segment, falls to a broadcast domain or logical switch connected to a T1 router acting as the gateway to that network. This approach provides a DNAT and SNAT control point and a firewall boundary.

The Services network is an exception. It shares a T1 router with any associated OD-Services# networks. Because these networks are considered part of the same system, inserting any NATs or firewall rules between them is not needed.

Load Balancing for PAS

Without NSX-T, you need to choose a suitable load balancer to send traffic to the Gorouters and other systems. Installations approaching production level typically use external load balancing from hardware appliance vendors or other network-layer solutions.

With NSX-T, load balancing is available in the SDN layer. These load balancers are a logical entity tied to the resources in the Edge Cluster and align to the network or networks represented by a T1 router. They function as a Layer 4 load balancer. SSL termination is available on the NSX-T load balancer. However, Pivotal recommends passing the SSL through to your Gorouters.

Common deployments of load balancing in PAS are as follows:

- HTTP/HTTPS traffic to and from Gorouters
- TCP traffic to and from TCP routers
- Diego Brain

NSX-T load balancers can support many VIPs. Consider deploying one load balancer per network (T1) and one-to-many VIPs on that load balancer per job. Edge Cluster resources are consumed for load balancing. When designing your deployment, consider how many load balancers are needed and how much capacity is available for them.

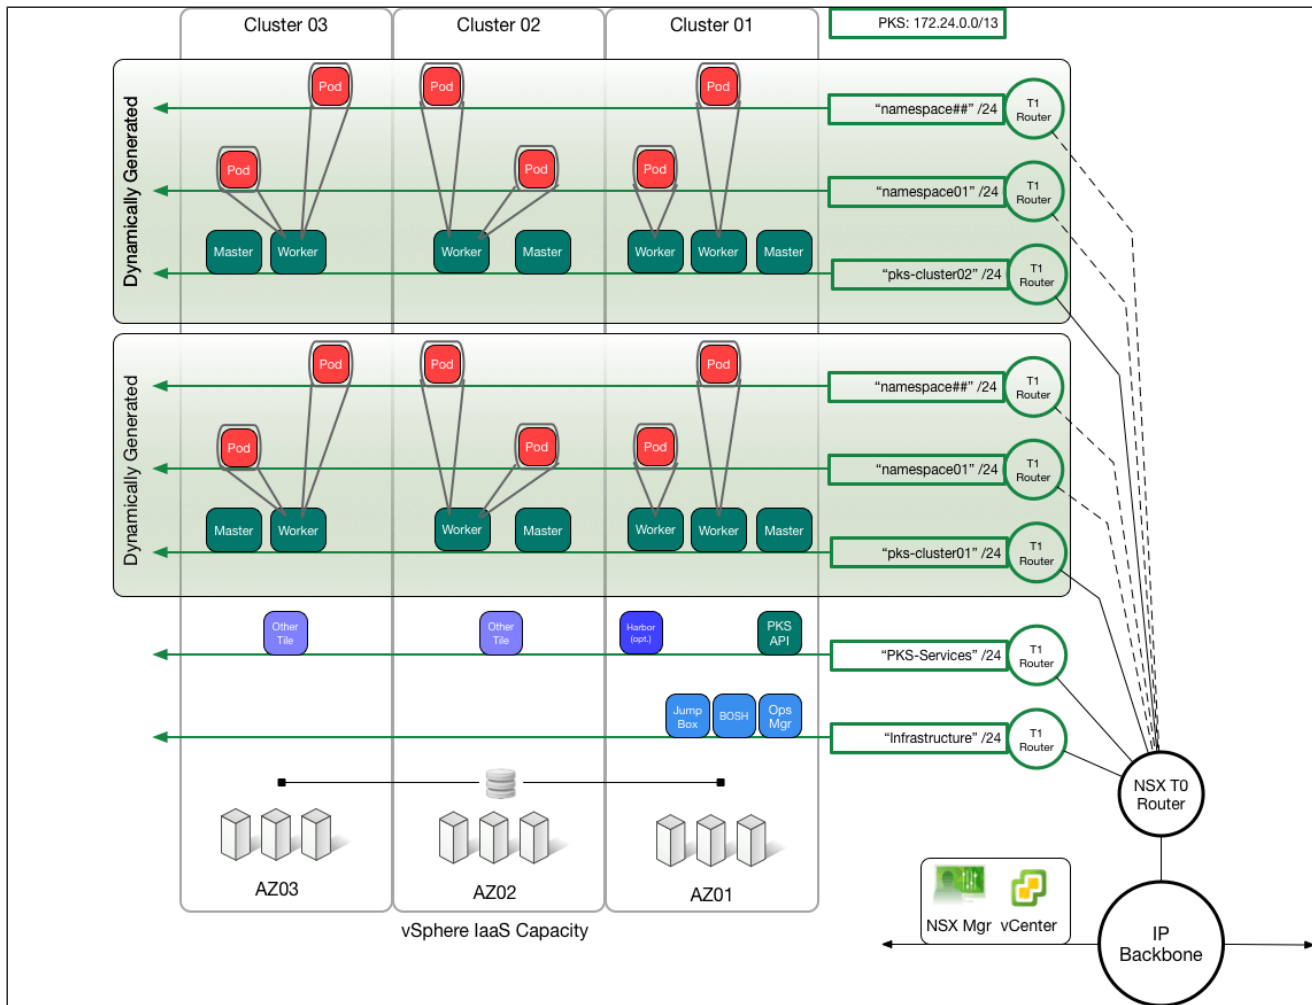

BOSH can manage the members of the server pools for the NSX-T load balancers using NS Groups.

PKS with NSX-T

NSX-T SDN is included in PKS by default, along with the associated licensing. To use NSX-T SDN and its dynamic constructs, you need to provide the following information when configuring PKS:

- NSX Manager host
- Username and password
- NSX Manager CA certificate
- T0 router to connect dynamically created namespace networks to
- NSX IP block from which to pull networks for pods per namespace
- NSX IP block from which to pull networks for each new cluster
- Floating IP pool ID created for externally facing IPs (NATs and VIPs)

For more information about configuring PKS with NSX-T networking, see [Installing and Configuring PKS with NSX-T Integration](#).

[View a larger version of this diagram](#)

New T1 routers are deployed on-demand as new namespaces are added to PKS. Because these can grow rapidly, allocate a large Pod IP block such as /14 in NSX-T, and then NSX-T provisions /24 address blocks for new namespaces. Reference the Pod IP block from your PKS tile configuration.

PKS v1.1.5 and later supports multiple master nodes. The number of master nodes is defined per plan in the PKS tile. You must use an odd number of master nodes to allow etcd to form a quorum. Pivotal recommends using at least 1 master node per AZ for HA and disaster recovery.

With NSX-T SDN, networks for both PKS clusters and pods are created dynamically. Pivotal recommends using multiple clusters instead of a single cluster with multiple namespaces. Multiple clusters provide security, customization per cluster, privileged containers, failure domains, and version choice.

Ingress Routing and Load Balancing for PKS

This section provides information about ingress routing (Layer 7) and load balancing (Layer 4) for your PKS deployment.

Ingress Routing

NSX-T provides a native ingress router. Third-party options include Istio or Nginx that are running as containers in the cluster.

Wildcard DNS entries are needed for pointing at the ingress service in the style of Gorouters in PAS. Domain information for ingress is defined in the manifest of your Kubernetes deployment. See the example below.

```
apiVersion: extensions/v1beta1
kind: Ingress
metadata:
  name: music-ingress
  namespace: music1
spec:
  rules:
  - host: music1.pks.domain.com
    http:
      paths:
      - path: /*
        backend:
          serviceName: music-service
          servicePort: 8080
```

Load Balancing

When pushing a Kubernetes deployment with `type` set to `LoadBalancer`, NSX-T automatically creates a new VIP for the deployment on the existing load balancer for that namespace.

You need to specify a listening and translation port in the service, along with a name for tagging. You also specify a protocol to use. See the example below.

```
apiVersion: v1
kind: Service
metadata:
  ...
spec:
  type: LoadBalancer
  ports:
  - port: 80
    targetPort: 8080
    protocol: TCP
    name: web
```

Storage Design

Shared storage is a requirement for PCF. You can allocate networked storage to the host clusters following one of two common approaches: horizontal or vertical. The approach you follow should reflect how your data center arranges its storage and host blocks in its physical layout.

The following describes the vertical and horizontal approaches to configuring shared storage:

- **Vertical:** You grant each cluster its own dedicated datastores, creating a cluster-aligned storage strategy. vSphere VSAN is an example of this architecture. The vertical alignment is the preferred choice for PCF as it matches the AZ model of the PaaS. Loss of storage in a cluster constitutes loss on an AZ, which is a recoverable failure when at least two more AZs are operational.
For example, with six datastores `ds01` through `ds06`, you assign datastores `ds01` and `ds02` to your first cluster, `ds03` and `ds04` to your second cluster, and `ds05` and `ds06` to your third cluster. You then instruct your first PCF installation to use `ds01`, `ds03`, and `ds05` and your second PCF installation to use `ds02`, `ds04`, and `ds06`. In this arrangement, all VMs in the same installation and cluster share a dedicated datastore.
- **Horizontal:** You grant all hosts access to all datastores and assign a subset to each installation.
For example, with six datastores `ds01` through `ds06`, you grant all nine hosts access to all six datastores. You then instruct your first PCF installation to use stores `ds01` through `ds03` and your second PCF installation to use `ds04` through `ds06`.

Warning: If you use the horizontal storage design approach, any storage loss could affect datastores in all AZs. This could result in downtime and unrecoverable loss of data. To avoid downtime and data loss, Pivotal recommends implementing the vertical storage design approach or implementing strong redundancy design at the storage array.

Highly redundant storage systems, such as hyperconverged systems, are the optimal choice for a fully HA PaaS. In addition, hyperconverged systems scale with capacity growth and are aligned to the AZ strategy of PCF.

To improve the resiliency of your deployment, you can use separate storage for the management plane of PCF, Ops Manager and BOSH, as well as separate storage for the blobstore.

Note: If a datastore is part of a vSphere storage cluster using sDRS (Storage DRS), you must disable the s-vMotion feature on any datastores used by PCF. Otherwise, s-vMotion activity can rename independent disks and cause BOSH to malfunction. For more information, see [How to Migrate PCF to a New Datastore in vSphere](#).

Storage Capacity

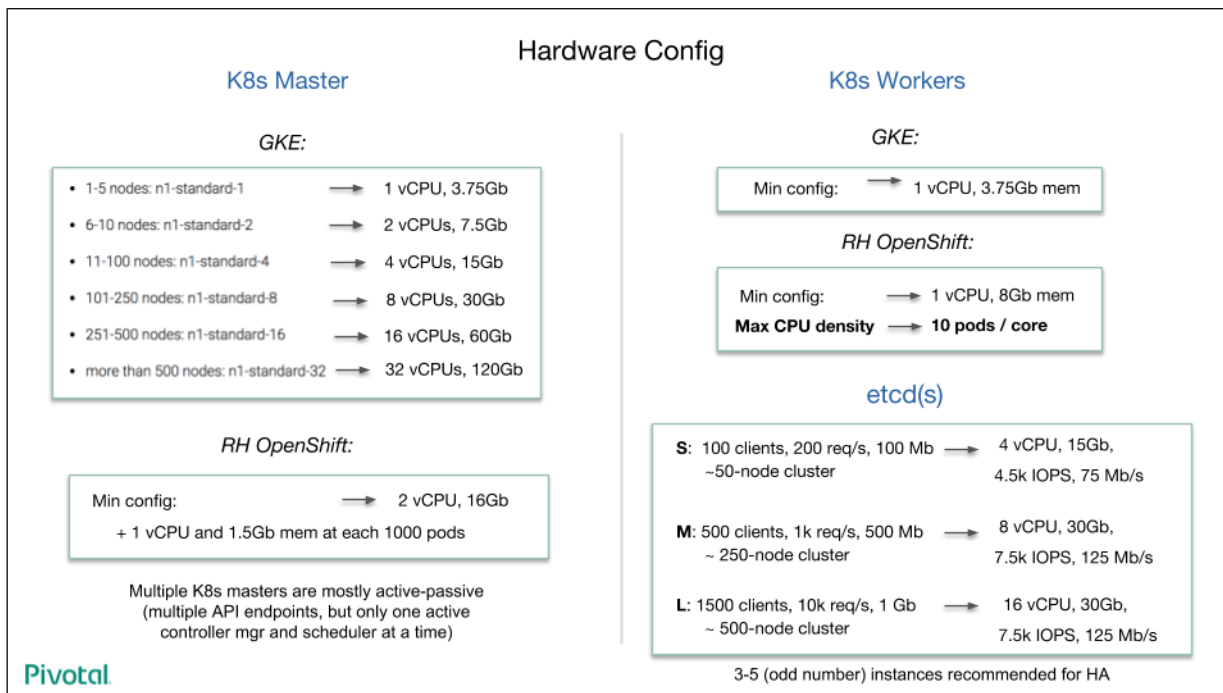

Pivotal recommends the following capacity allocation for PAS installations:

- For production use, at least 8 TB of data storage, either as one 8-TB store or a number of smaller volumes adding up to 8 TB. Frequent development may require significantly more storage to accommodate new code and buildpacks.
- For small installations, 4-6 TB of data storage is recommended.

The primary consumer of storage is NFS or WebDAV.

Note: PCF does not currently support using vSphere storage clusters with the versions of PCF validated for this reference architecture. Datastores should be listed in the vSphere tile by their native name, not the cluster name created by vCenter for the storage cluster.

When planning storage allocation for PKS installations based on Pod and Node needs, consider the following chart.

Compute and HA Considerations

In PAS, a consolidation ratio for containers should follow a conservative 4:1 ratio of vCPUs to pCPUs. You can use a more conservative ratio, which is 2:1.

A standard Diego cell is 4x16 (XL) by default. At a 4:1 ratio, you have a 16-vCPU budget, or about 12 containers.

If you want to run more containers in a cell, scale the vCPUs accordingly. However, high core count VMs become increasingly hard to schedule on the pCPU without high physical core counts in the socket.

HA considerations include the following:

- For non-production environments, the number of AZs that PAS requires for HA depends on the location of its system databases.
 - With external databases, PAS requires at least two AZs for HA.
 - With internal system databases, PAS requires at least three AZs for HA.

PCF achieves redundancy through the AZ construct and the loss of an AZ is not considered catastrophic. BOSH Resurrector can replace lost VMs as needed to repair a foundation. Foundation backup and restoration is accomplished externally by BOSH Backup and Restore (BBR). For information about BBR, see [Backing Up and Restoring Pivotal Cloud Foundry](#).

- PKS has no inherent HA capabilities to design for. To support PKS, design HA at the IaaS, storage, power, and access layers.

PCF achieves redundancy through the AZ construct, and the loss of an AZ is not considered catastrophic. BOSH Resurrector replaces lost VMs as needed to repair a foundation.

Foundation backup and restoration is accomplished externally by BOSH Backup and Restore (BBR). For information about BBR, see [Backing Up and](#)

[Restoring Pivotal Cloud Foundry](#) [↗](#).

Scaling and Capacity Management

This section provides information about scaling and capacity management for PCF.

Small PCF Installations

A small-sized PCF foundation looks as follows:

- 1 vSphere cluster/1 AZ
- 2 resource pools: 1 for NSX components and 1 for PAS or PKS
- 3 hosts minimum for vSphere HA (4 hosts for vSphere VSAN)
- Shared storage/VSAN
- 1 NSX Manager
- 3 NSX controllers
- 2 large edge VMs in a cluster
- PCF: Ops Manager, the BOSH Director, and Small Footprint Runtime

This approach is intended for designing a proof of concept or development-only system. Small Footprint Runtime has no upgrade path to the standard PAS tile.

Medium PCF Installations

A medium-sized PCF foundation looks as follows:

- 2 vSphere clusters/2 AZs
- 3 resource pools: 1 for NSX components and 2 for PAS/1 for PKS
- 3 hosts minimum for vSphere HA (4 hosts for vSphere VSAN) per cluster
- Shared storage/VSAN
- 1 NSX Manager
- 3 NSX controllers
- 2 large edge VMs in a cluster
- PCF: Ops Manager, the BOSH Director, and PAS/PKS

For this design, Pivotal recommends replacing Small Footprint Runtime with PAS. The second AZ doubles compute capacity and expands the NSX-T footprint.

Production-Ready PCF Installations

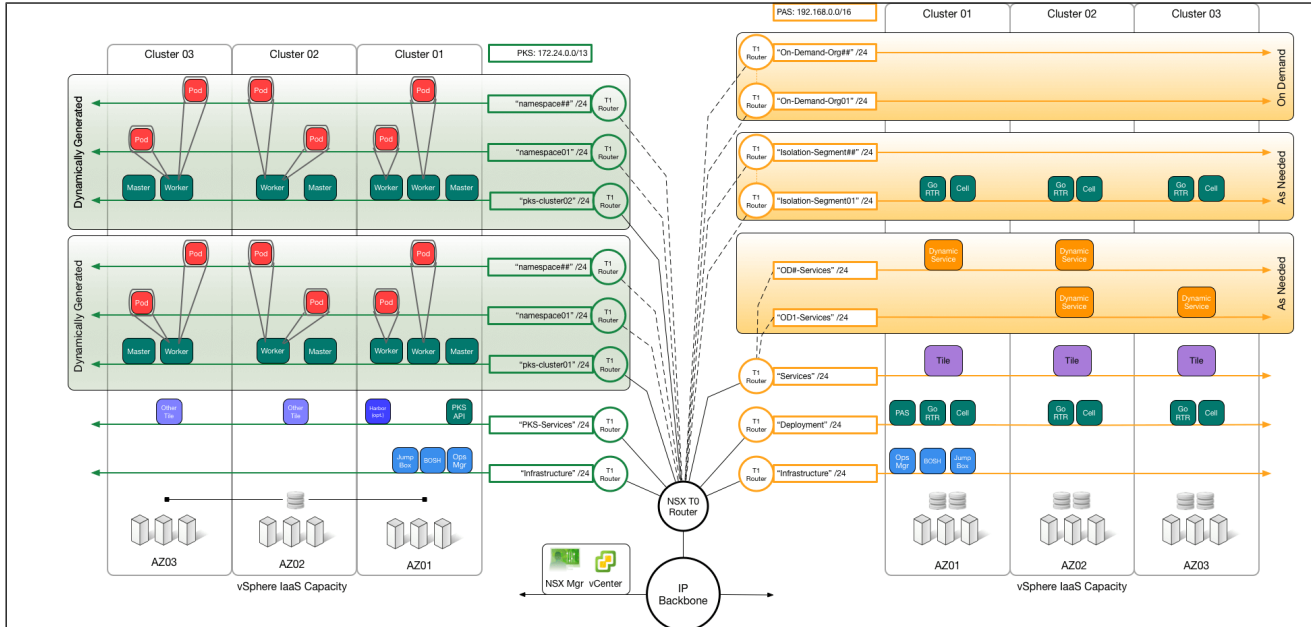

A production-ready PCF foundation looks as follows:

- 3 vSphere clusters/3 AZs
- 4 resource pools: 1 for NSX components and 3 for PAS/1 for PKS
- 3 hosts minimum for vSphere HA (4 hosts for vSphere VSAN)
- Shared Storage/VSAN
- 1 NSX Manager
- 3 NSX Controllers
- 3 large edge VMs in a cluster
- PCF: Ops Manager, the BOSH Director, and PAS/PKS

PAS and PKS with NSX-T

A fully meshed installation of PCF v2.2 or later designed using the recommendations provided in this topic looks as follows:

Note: You should not share an Ops Manager and BOSH Director installation between PKS and PAS in a production environment.

[View a larger version of this diagram](#)

Common components are the NSX T0 router and the associated T1 routers. This approach ensures that any cross-traffic between PKS and PAS apps stays within the bounds of the T0. This also provides a one-stop access point to the whole installation, which simplifies deployment automation for multiple, identical installations.

Note that each design, green PKS and orange PAS, has its own Ops Manager and BOSH Director installation. You should not share an Ops Manager and BOSH Director installation between PKS and PAS.

AZs are aligned to vSphere clusters, with resource pools as an optional organizational tool to place multiple foundations into the same capacity. You can align PKS to any AZ or cluster. Keeping PKS and PAS in completely separate AZs is not required.

You can use resource pools in vSphere clusters as AZ constructs to stack different installations of PCF. As server capacity continues to increase, the efficiency of deploying independent server clusters only for one installation is low. For example, customers are commonly deploying servers with 768-GB RAM and greater.

To allow for max capacity growth, consider using an NSX-T installation per foundation.

If you want to split the PAS and PKS installations into separate network trees, behind separate T0 routers, ensure that approach meets your needs by reviewing VMware's recommendations for T0 to T0 routing. For more information, see [Reference Design Guide for PAS and PKS with VMware NSX-T Data Center](#) in the VMware documentation.

Using Edge Services Gateway on VMware NSX

This cookbook provides guidance on how to configure the NSX firewall, load balancing, and NAT/SNAT services for Pivotal Cloud Foundry (PCF) on vSphere installations. These NSX-provided services take the place of an external device or the bundled HAProxy VM in PCF.

This document presents the reader with fundamental configuration options of an Edge Services Gateway (ESG) with PCF and vSphere NSX. Its purpose is not to dictate the settings required on every deployment, but instead to empower the NSX Administrator with the ability to establish a known good “base” configuration and apply specific security configurations as required.

If you are using NSX, the specific configurations described here supersede any general recommendations in the [Preparing Your Firewall](#) topic.

Assumptions

This document assumes that the reader has the level of skill required to install and configure the following products:

- VMware vSphere v5.5 or greater
- NSX v6.1.x or greater
- PCF v1.6 or greater

For detailed installation and configuration information about these products, see the following:

- [vSphere Documentation](#) 
- [NSX Installation and Upgrade Guide](#) 
- [Reference Design: VMware NSX for vSphere \(NSX\) Network Virtualization Design Guide](#) 
- [Pivotal Cloud Foundry Documentation](#) 

General Overview

This cookbook follows a three-step recipe to deploy PCF behind an ESG:

1. Configure Firewall
2. Configure Load Balancer
3. Configure NAT/SNAT

The ESG can scale to accommodate very large PCF deployments as needed.

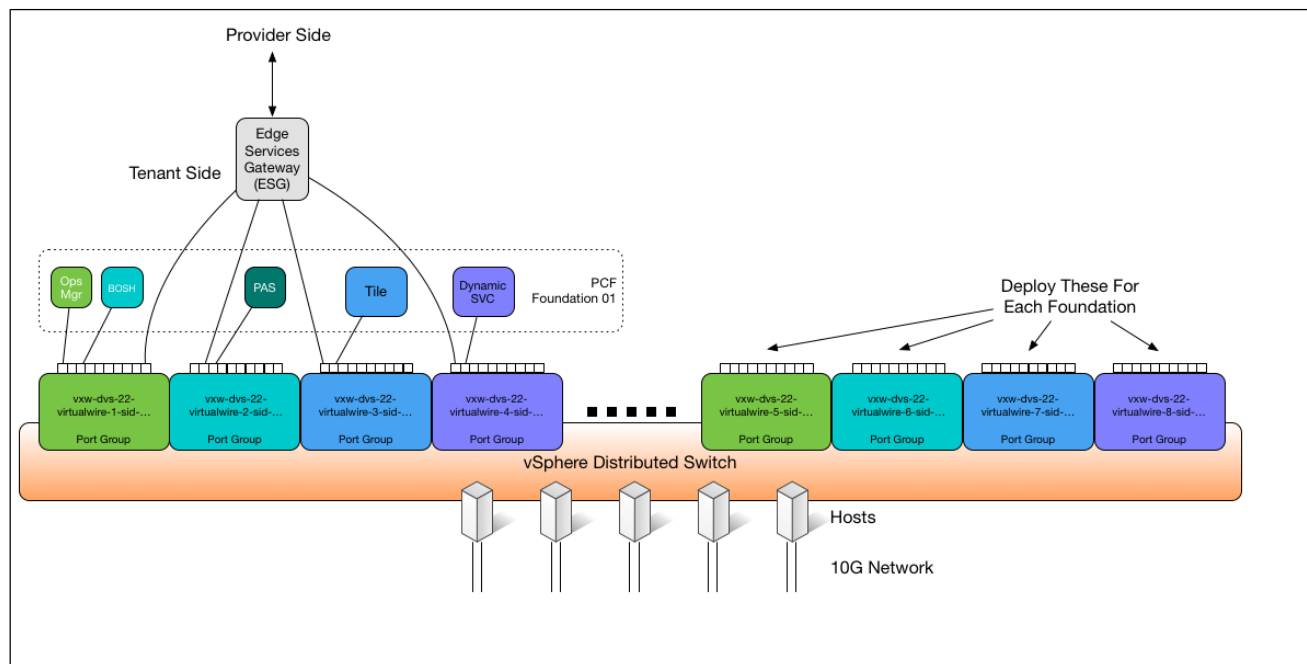

This cookbook focuses on a single-site deployment and makes the following design assumptions:

- There are five non-routable networks on the tenant (inside) side of the ESG.
 - The **Infra** network is used to deploy Ops Manager and BOSH Director.
 - The **Deployment** network is used exclusively by Pivotal Application Service (PAS) to deploy Cells that host apps and related elements.
 - The **CF Tiles** network is used for all other deployed tiles in a PCF installation.
 - The **Services** network is used by BOSH Director for service tiles.
 - The **Container-to-Container** network is used for container to container communication in the Cells.
- There is a single service provider (outside) interface on the ESG that provides Firewall, Load Balancing and NAT/SNAT services.
- The service provider (outside) interface is connected appropriately to the network backbone of the environment, as either routed or non-routed depending on the design. This cookbook does not cover provisioning of the uplink interface.
- Routable IP addresses should be applied to the service provider (outside) interface of the ESG. Pivotal recommends that you apply 10 consecutive routable IP addresses to each ESG.
 - One reserved for NSX use (Controller to Edge I/F)
 - One for NSX Load Balancer to Gorouters
 - One for NSX Load Balancer to Diego Brains for SSH to apps
 - One routable IP address, used to access the Ops Manager frontend
 - One routable IP address, used with SNAT egress
 - Five for future use

Pivotal recommends that operators deploy the ESGs as high availability (HA) pairs in vSphere. Also, Pivotal recommends that they be sized “large” or greater for any pre-production or production use. The deployed size of the ESG impacts its overall performance, including how many SSL tunnels it can terminate.

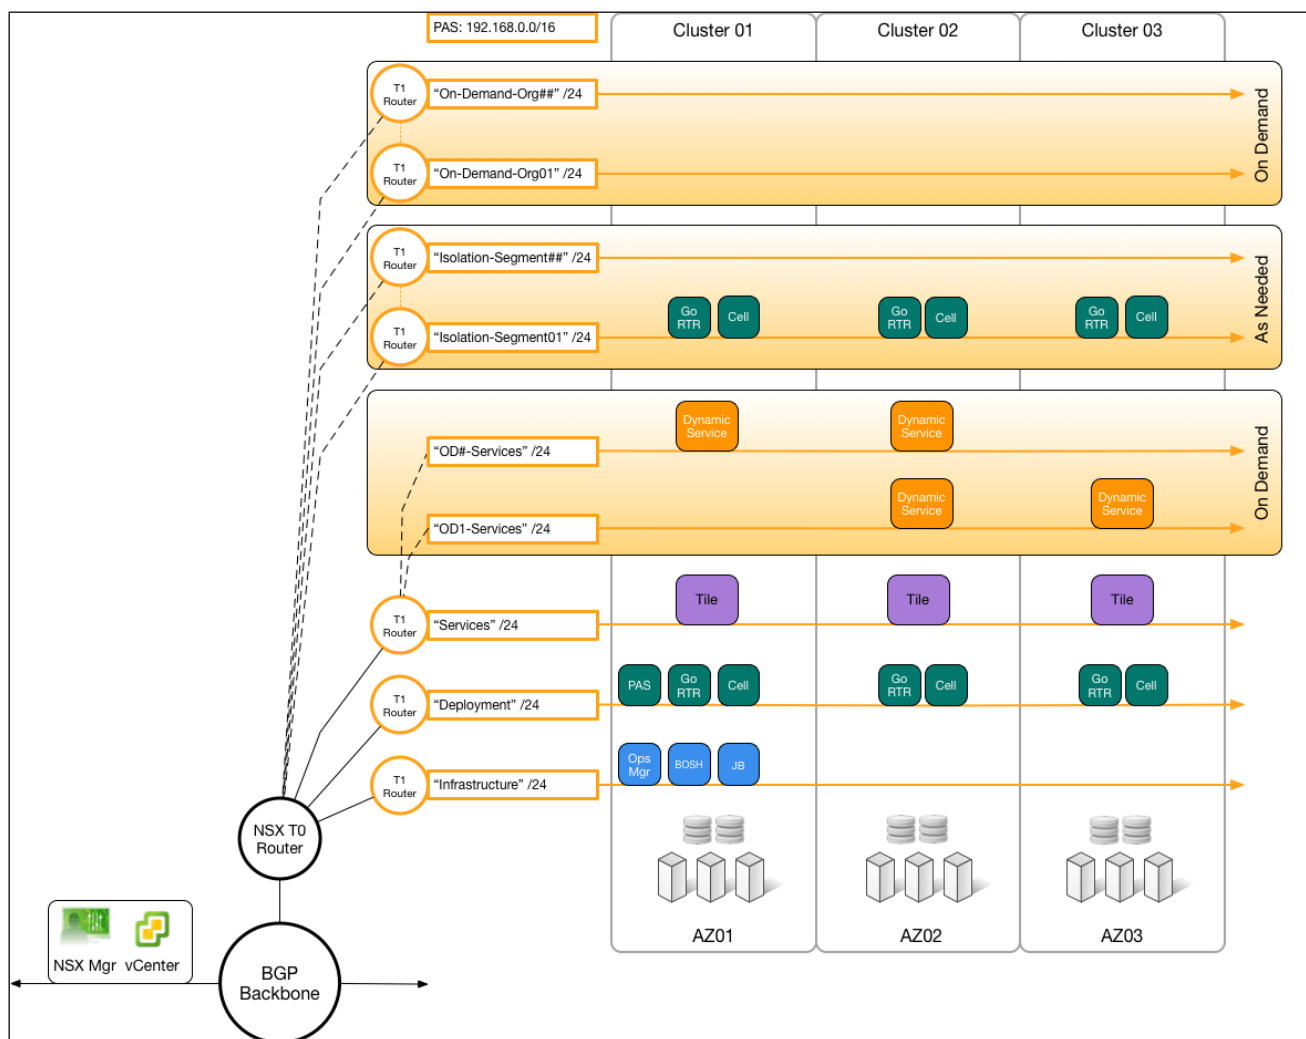

The ESGs have an interface in each port group used by PCF as well as a port group on the service provider (outside), often called the “transit network.” Each PCF installation has a set of port groups in a vSphere DVS to support connectivity, so that the ESG arrangement is repeated for every PCF install. It is not necessary to build a DVS for each ESG/PCF install. You do not re-use an ESG amongst PCF deployments. NSX Logical Switches (VXLAN vWires) are ideal candidates for use with this architecture.

The following diagram provides an example of port groups used with an ESG:

[View a larger version of this diagram.](#)

The following is an example of a network architecture deployment.

[View a larger version of this diagram.](#)

The following diagram illustrates container-to-container networking. The overlay addresses are wrapped and transported using the underlay deployment subnet.

[View a larger version of this diagram.](#)

Prep Step: Configure DNS and Network Prerequisites

As a prerequisite, create wildcard DNS entries for system and apps domains in PCF. Map these domains to the selected IP address on the uplink (outside) interface of the ESG in your DNS server.

The wildcard DNS [A](#) record must resolve to an IP address associated with the outside interface of the ESG for it to function as a load balancer. You can either use a single IP address to resolve both the system and apps domain, or one IP address for each.

In addition, assign the following IP addresses and address ranges within your network:

1. Assign IP Addresses to the “Uplink” (outside) interface
 - Typically you have one SNAT and three DNATs per ESG.
 - IP associated for SNAT use: All PCF internal IP addresses appear to be coming from this IP address at the ESG.
 - IP associated with Ops Manager DNAT: This IP address is the publicly routable interface for Ops Manager UI and SSH access.
2. Assign “Internal” Interface IP Address Space to the Edge Gateway.
 - 192.168.10.0/26 = PCF Deployment Network (Logical Switch or Port Group)
 - 192.168.20.0/22 = Deployment Network for PAS tile
 - 192.168.24.0/22 = CF Tiles Network for all Tiles besides PAS
 - 192.168.28.0/22 = Dynamic Services network for BOSH Director-managed service tiles.
 - 10.255.0.0/16 = Container-to-Container network for intercontainer communication.

You must update the security group and load balancer information for your PCF deployments using NSX-V on vSphere through the Ops Manager API. See [Updating NSX Security Group and Load Balancer Information](#) for more information.

Step 1: Configure Firewall

This procedure populates the ESG internal firewall with rules to protect a PCF installation.

These rules provide granular control on what can be accessed within a PCF installation. For example, rules can be used to allow or deny another PCF installation behind a different ESG access to apps published within the installation you are protecting.

This step is not required for the installation to function properly when the firewall feature is disabled or set to “Allow All.”

To configure the ESG firewall, navigate to **Edge, Manage, Firewall** and set the following:

| Name | Source | Destination | Service | Action |
|-------------------------------|---|---|---------------------|--------|
| Allow Ingress -> Ops Manager | any | IP_of_OpsMgr | SSH, HTTP, HTTPS | Accept |
| Allow Ingress -> PAS | any | IP_of_NSX-LB | HTTP, HTTPS | Accept |
| Allow Ingress -> SSH for Apps | any | tcp:IP_of_DiegoBrain:2222 | any | Accept |
| Allow Ingress -> TCProuter | any | tcp:IP_of_NSX-TCP-LB:5000 | any | Accept |
| Allow Inside <-> Inside | 192.168.10.0/26 192.168.20.0/22 192.168.24.0/22 192.168.28.0/22 | 192.168.10.0/26 192.168.20.0/22 192.168.24.0/22 192.168.28.0/22 | any | Accept |
| Allow Egress -> IaaS | 192.168.10.0/26 | IP_of_vCenter IPs_of_ESXi-Svrs | HTTP, HTTPS | Accept |
| Allow Egress -> DNS | 192.168.0.0/16 | IPs_of_DNS | DNS, DNS-UDP | Accept |
| Allow Egress -> NTP | 192.168.0.0/16 | IPs_of_NTP | NTP | Accept |
| Allow Egress -> SYSLOG | 192.168.0.0/16 | IPs_of_Syslog:514 | SYSLOG | Accept |
| Allow ICMP | 192.168.10.0/26 | * | ICMP | Accept |
| Allow Egress -> LDAP | 192.168.10.0/26 192.168.20.0/22 | IPs_of_LDAP:389 | LDAP, LDAP-over-ssl | Accept |
| Allow Egress -> All Outbound | 192.168.0.0/16 | any | any | Accept |
| Default Rule | any | any | any | Deny |

Step 2: Configure Load Balancer

The ESG provides software load balancing functionality, equivalent to the bundled HAProxy that is included with PCF, or hardware appliances such as an F5 or A10 load balancer.

This step is required for the installation to function properly.

There are seven high level steps to this procedure:

1. Import SSL certificates to the Edge for SSL termination.
2. Enable the load balancer.
3. Create Application Profiles in the Load Balancing tab of NSX.
4. Create Application Rules in the load balancer.
5. Create Service Monitors for each pool type.
6. Create Application Pools for the multiple groups needing load balancing.
7. Create a virtual server (also known as a VIP) to pool balanced IP addresses.

What you will need:

- PEM files of SSL certificates provided by the certificate supplier for only this installation of PCF, or the self-signed SSL certificates generated during PCF installation.

In this procedure you marry the ESG's IP address used for load balancing with a series of internal IP addresses provisioned for Gorouters in PCF. It is important to know the IP addresses used for the Gorouters beforehand.

These IP addresses can be pre-selected or reserved prior to deployment (recommended) or discovered after deployment by looking them up in BOSH Director, which lists them in the release information of the PAS installation.

Step 2.1: Import SSL Certificate

PCF requires SSL termination at the load balancer.

 **Note:** If you intend to pass SSL termination through the load balancer directly to the Gorouters, you can skip the step below and select **Enable SSL Passthru** on the **HTTPS Application Profile**.

To enable SSL termination at the load balancer in ESG, access the ESG UI and do the following:

1. Select **Edge, Manage, Settings**, and then **Certificates**.
2. Click Green Plus button to Add Certificate.
3. Insert PEM file contents from the Networking configuration screen of PAS.
4. Save the results.

Step 2.2: Enable the Load Balancer

To enable the load balancer, access the ESG UI and do the following:

1. Select **Edge, Manage, Load Balancer**, and then **Global Configuration**.
2. Edit load balancer global configuration.
3. Enable load balancer.
4. Enable acceleration.
5. Set logging to desired level (**Info** or greater).

Step 2.3: Create Application Profiles

The Application Profiles allow advanced **x-forwarded** options as well as linking to the SSL Certificate. You must create three Profiles: **PCF-HTTP**, **PCF-HTTPS** and **PCF-TCP**.

To create the application profiles, access the ESG UI and do the following:

1. Select **Edge, Manage, Load Balancer**, and then **Global Application Profiles**.
2. Create/Edit Profile and make the **PCF-HTTP** rule, turning on **Insert X-Forwarded-For HTTP header**.

Edit Profile

Name:

Type: ▼

☐ Enable SSL Passthrough

HTTP Redirect URL:

Persistence: ▼

Cookie Name:

Mode: ▼

Expires in (Seconds):

☒ Insert X-Forwarded-For HTTP header

☐ Enable Pool Side SSL

Virtual Server Certifica...

☐ Configure Service Certificate

| | Common Name | Issuer | Validity |
|-----|-------------|----------|-----------------------|
| (+) | *.f..... | *.f..... | Mon Apr 13 2015 - Wed |
| | | | |
| | | | |
| | | | |
| | | | |
| | | | |
| | | | |
| | | | |
| | | | |
| | | | |

Cipher: ▼

Client Authentication: ▼

3. Create/Edit Profile and make the **PCF-HTTPS** rule, same as before, but add the service certificate inserted before. If encrypting TLS traffic to the Gorouters, turn on **Enable Pool Side SSL**. Otherwise, leave it unchecked.

4. Create/Edit Profile and make **PCF-TCP** rule, with the Type set to TCP.

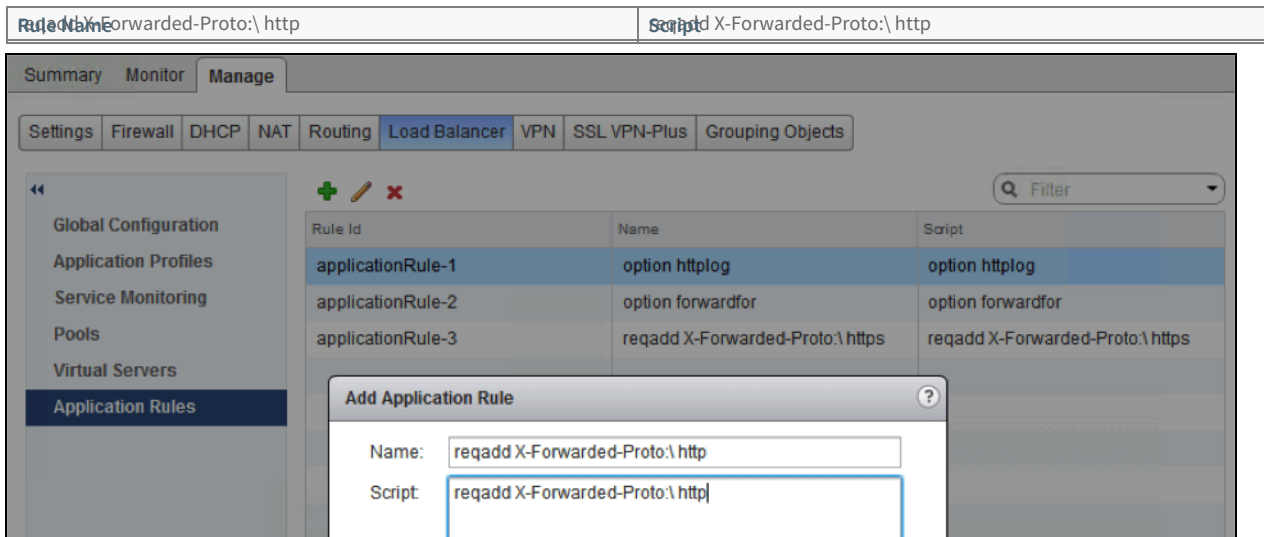

Step 2.4: Create Application Rules

In order for the ESG to perform proper `x-forwarded` requests, you need to add a few HAProxy directives to the ESG Application Rules. NSX supports most directives that HAProxy supports.

To create the application rules, access the ESG UI and do the following:

1. Select **Edge**, **Manage**, **Load Balancer**, and then **Application Rules**.
2. Copy and paste the table entries below into each field, one per rule.

| Rule Name | Script |
|----------------------------------|----------------------------------|
| option httplog | option httplog |
| reqadd X-Forwarded-Proto:\ https | reqadd X-Forwarded-Proto:\ https |

Step 2.5: Create Monitors For Pools

NSX ships with several load balancing monitoring types pre-defined. These types are for HTTP, HTTPS and TCP. For this installation, operators build new monitors matching the needs of each pool to ensure correct 1:1 monitoring for each pool type.

To create monitors for pools, access the ESG UI and do the following:

1. Select **Edge**, **Manage**, **Load Balancer**, and then **Service Monitoring**.
2. Create a new monitor for `http-routers`, and keep the defaults.
3. Set the Type to `HTTP`.
4. Set the Method to `GET`.
5. Set the URL to `/health`.
6. Create a new monitor for `tcp-routers`, and keep the defaults.
7. Set the type to `HTTP`.
8. Set the Method to `GET`.
9. Set the URL to `/health`.
10. Create a new monitor for `diego-brains`, and keep the defaults.
11. Set the type to `TCP`.

These monitors are selected during the next step when pools are created. A pool and a monitor are matched 1:1.

Step 2.6: Create Pools of Multi-Element PCF Targets

The following steps creates the pools of resources that ESG load-balances to: the Gorouter, TCP Router, and Diego Brain jobs deployed by BOSH Director. If the IP addresses specified in the configuration do not exactly match the IP addresses reserved or used for the resources, then the pool will not effectively load balance.

Step 2.6a: Create Pool for `http-routers`

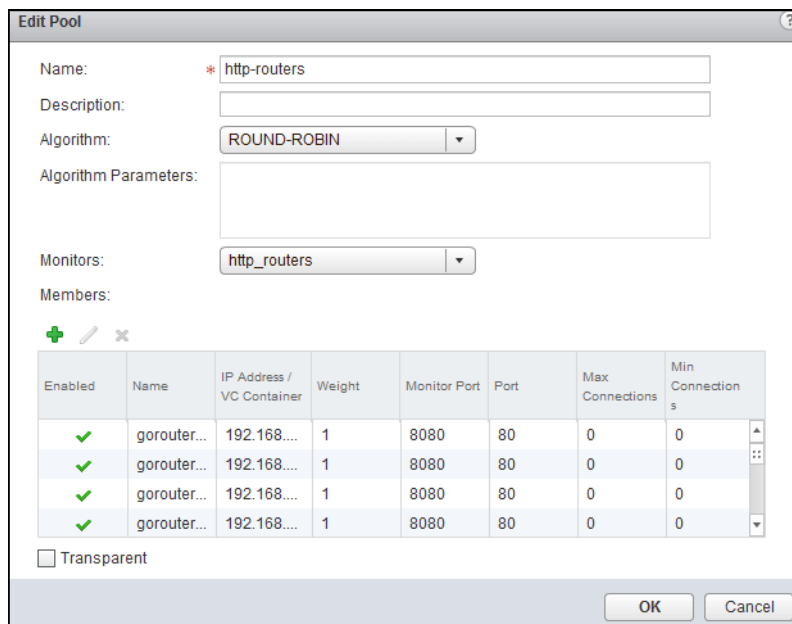

To create pool for `http-routers`, access the ESG UI and do the following:

1. Select **Edge**, **Manage**, **Load Balancer**, and then **Pools**.

2. Enter ALL the IP addresses reserved for the Gorouters into this pool. If you reserved more addresses than you have Gorouters, enter the addresses anyway and the load balancer ignores the missing resources as “down”.

 **Note:** If your deployment matches the [Reference Architecture for PCF on vSphere](#), these IP addresses are in the 192.168.20.0/22 address space.

3. Set the **Port** to 80 and **Monitor Port** to 8080. The assumption is that internal traffic from the ESG load balancer to the Gorouters is trusted because it is on a VXLAN secured within NSX. If using encrypted TLS traffic to the Gorouter inside the VXLAN, set the **Port** to 443.
4. Set the **Algorithm** to `ROUND-ROBIN`.

Edit Pool

Name: * http-routers

Description:

Algorithm: `ROUND-ROBIN`

Algorithm Parameters:

Monitors: http_routers

Members:

| Enabled | Name | IP Address / VC Container | Weight | Monitor Port | Port | Max Connections | Min Connections |
|---------|-------------|---------------------------|--------|--------------|------|-----------------|-----------------|
| ✓ | gorouter... | 192.168.20.1 | 1 | 8080 | 80 | 0 | 0 |
| ✓ | gorouter... | 192.168.20.2 | 1 | 8080 | 80 | 0 | 0 |
| ✓ | gorouter... | 192.168.20.3 | 1 | 8080 | 80 | 0 | 0 |
| ✓ | gorouter... | 192.168.20.4 | 1 | 8080 | 80 | 0 | 0 |

☐ Transparent

OK Cancel

5. Set **Monitors** to `http-routers`.

Step 2.6b: Create Pool for `tcp-routers`

1. Select **Edge**, **Manage**, **Load Balancer**, and then **Pools**.
2. Enter ALL the IP addresses reserved for TCP Routers into this pool. If you reserved more addresses than you have VMs, enter the addresses anyway and the load balancer ignores the missing resources as “down”.

 **Note:** If your deployment matches the [Reference Architecture for PCF on vSphere](#), these IP addresses are in the 192.168.20.0/22 address space.

3. Set the **Port** to empty (these numbers vary) and the **Monitor Port** to 80.
4. Set the **Algorithm** to `ROUND-ROBIN`.
5. Set the **Monitors** to `tcp-routers`.

Step 2.6c: Create Pool for `diego-brains`

1. Select **Edge**, **Manage**, **Load Balancer**, and then **Pools**.
2. Enter ALL the IP addresses reserved for Diego Brains into this pool. If you reserved more addresses than you have VMs, enter the addresses anyway and the load balancer will just ignore the missing resources as “down”.

 **Note:** If your deployment matches the [Reference Architecture for PCF on vSphere](#), these IP addresses are in the 192.168.20.0/22 address space.

3. Set the **Port** to 2222 and the **Monitor Port** to 2222.
4. Set the **Algorithm** to `ROUND-ROBIN`.

5. Set the Monitors to `diego-brains`.

Step 2.7: Create Virtual Servers

This is the Virtual IP (VIP) that the load balancer uses to represent the pool of Gorouters to the outside world. This also links the Application Policy, Application Rules, and backend pools to provide PCF load balancing services. This is the interface that the load balancer balances **from**. You create three Virtual Servers.

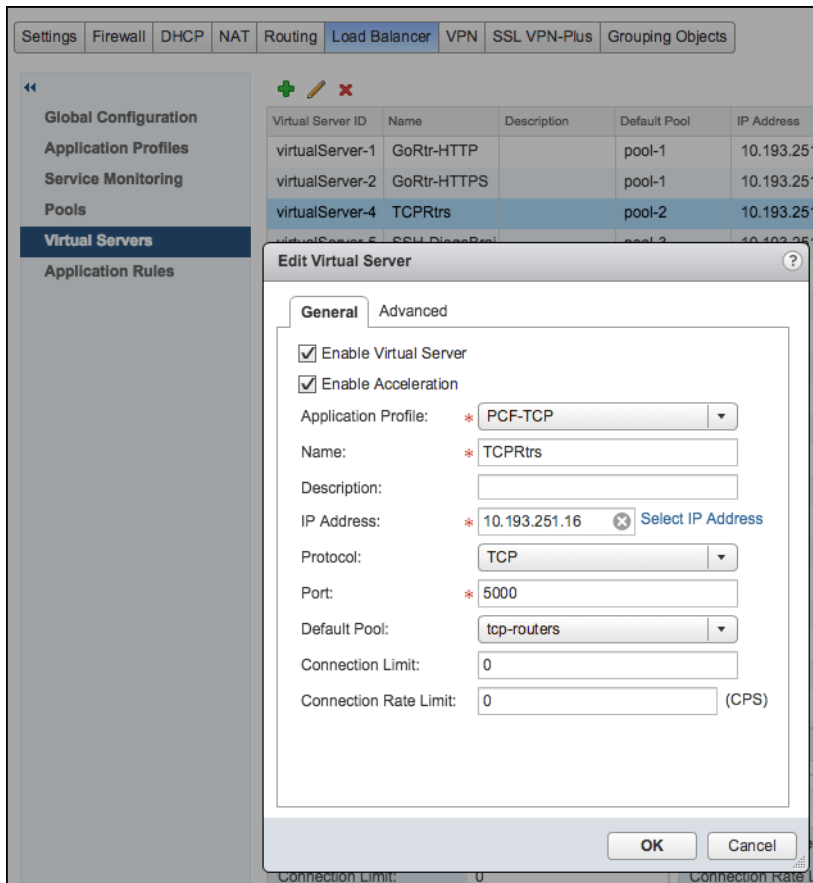

1. Select **Edge**, **Manage**, **Load Balancer**, and then **Virtual Servers**.
2. Select an IP address from the available routable address space allocated to the ESG. For information about reserved IP addresses, see [General Overview](#).
3. Create a new Virtual Server named `GoRtr-HTTP` and select Application Profile `PCF-HTTP`.
 - Use **Select IP Address** to select the IP address to use as a VIP on the uplink interface.
 - Set **Protocol** to match the **Application Profile** protocol (HTTP) and set **Port** to match the protocol (80).
 - Set **Default Pool** to the pool name set in [Step 2.6a: Create Pool for http-routers](#). This connects this VIP to the pool of resources being balanced to.
 - Ignore **Connection Limit** and **Connection Rate Limit** unless these limits are desired.
 - Switch to **Advanced Tab** on this Virtual Server.
 - Use the green plus to add/attach three Application Rules to this Virtual Server:
 - option httplog
 - reqadd X-Forwarded-Proto:\ http

 **Note:** Be careful to match protocol rules to the protocol `VIP-HTTP` to `HTTP` and `HTTPS` to `HTTPS`.

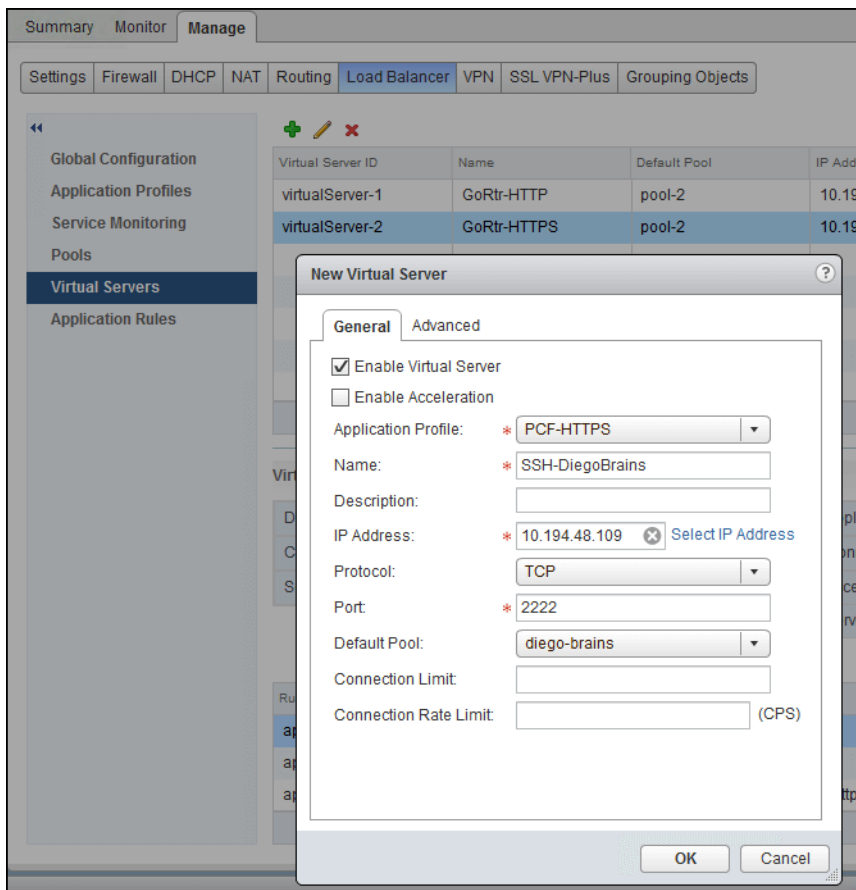

4. Create a new Virtual Server named `GoRtr-HTTPS` and select Application Profile `PCF-HTTPS`.
 - Use **Select IP Address** to select the **same IP address** to use as a VIP on the uplink interface.
 - Set **Protocol** to match the **Application Profile** protocol (`HTTPS`) and set **Port** to match the protocol (443).
 - Set **Default Pool** to the pool name set in [Step 2.6a: Create Pool for http-routers](#) (`http-routers`). This connects this VIP to that pool of resources being balanced to.
 - Ignore **Connection Limit** and **Connection Rate Limit** unless these limits are desired.
 - Switch to **Advanced Tab** on this Virtual Server.
 - Use the green plus to add/attach three Application Rules to this Virtual Server:
 - option httplog
 - reqadd X-Forwarded-Proto:\ https

 **Note:** Be careful to match protocol rules to the protocol `VIP-HTTP` to `HTTP` and `HTTPS` to `HTTPS`.

5. Create a new Virtual Server named `TCPRtr` and select Application Profile `PCF-TCP`.
 - Use **Select IP Address** to select the IP address to use as a VIP on the uplink interface.
 - Set **Protocol** to match the **Application Profile** protocol (TCP) and set **Port** to match the protocol (5000).
 - Set **Default Pool** to the pool name set in [Step 2.6b: Create Pool for tcp-routers](#) (`tcp-routers`). This connects this VIP to the pool of resources being balanced to.
 - Ignore **Connection Limit** and **Connection Rate Limit** unless these limits are desired.

6. Create a new Virtual Server named `SSH-DiegoBrains` and select Application Profile `PCF-HTTPS`.
 - Use **Select IP Address** to select the same IP address to use as a VIP on the uplink interface if you want to use this address for SSH access to apps. If not, select a different IP address to use as the VIP.
 - Set **Protocol** to TCP and set **Port** to 2222.
 - Set **Default Pool** to the pool name set in [Step 2.6c: Create Pool for diego-brains](#) (`diego-brains`). This connects this VIP to that pool of resources being balanced to.
 - Ignore **Connection Limit** and **Connection Rate Limit** unless these limits are desired.

Step 3: Configure NAT/SNAT

The ESG obfuscates the PCF installation through network translation. The PCF installation is placed entirely on non-routable RFC-1918 network address space, so you must translate routable IP addresses to non-routable IP addresses to make connections.

Note: Correct NAT/SNAT configuration is required for the PCF installation to function as expected.

| Action | Applied on Interface | Original IP | Original Port | Translated IP | Translated Port | Protocol | Description |
|--------|----------------------|-------------------|---------------|-------------------|-----------------|----------|------------------------------|
| SNAT | uplink | 192.168.0.0/16 | any | IP_of_PCF | any | any | All Nets Egress |
| DNAT | uplink | IP_of_OpsMgr | any | 192.168.10.OpsMgr | any | tcp | OpsMgr Mask for external use |
| SNAT | infra | 192.168.10.OpsMgr | any | IP_of_OpsMgr | any | tcp | OpsMgr Mask for internal use |
| DNAT | infra | IP_of_OpsMgr | any | 192.168.10.OpsMgr | any | tcp | OpsMgr Mask for internal use |

Note: The NAT/SNAT on the `infra` network in this table is an example of an optional **Hairpin NAT** rule to allow VMs within the **Infrastructure** network to access the Ops Manager API. This is because the Ops Manager hostname and the API HTTPS endpoint are registered to the Ops Manager external IP address. A pair of Hairpin NAT rules are necessary on **each** internal network interface that requires API access to Ops Manager. You should create these rules only if the network must access the Ops Manager API.

NAT/SNAT functionality is not required if routable IP address space is used on the Tenant Side of the ESG. At that point, the ESG simply performs routing between the address segments.

Note: NSX generates a number of DNAT rules based on load balancing configs. You can safely ignore these.

Additional Notes

The ESG also supports scenarios where Private RFC subnets and NAT are not utilized for **Deployment** or **Infrastructure** networks, and the guidance in

this document can be modified to meet those scenarios.

Additionally, the ESG supports up to 10 Interfaces allowing for more Uplink options if necessary.

The use of Private RFC-1918 subnets for PCF Deployment networks was chosen due to its popularity with customers. ESG devices are capable of leveraging ECMP, OSPF, BGP, and IS-IS to handle dynamic routing of customer and/or public L3 IP space. That design is out of scope for this document, but is supported by VMware NSX and Pivotal PCF.

Upgrading vSphere without PCF Downtime

This topic describes how to upgrade the vSphere components that host your Pivotal Cloud Foundry (PCF) installation without service disruption.

Minimum Requirements

At a bare minimum, vSphere contains the following components:

- vCenter Server
- one or more ESXi hosts

You cannot perform an in-place upgrade of vSphere without at least two ESXi hosts in your cluster.

If you do not meet this requirement (in other words, you have insufficient resources to evacuate an entire host), then you may experience PCF downtime during the upgrade.

To upgrade vSphere with only one ESXi host or without sufficient headroom capacity, you must reduce your PCF installation size. In other words, you can either reduce the number of Diego cells in your deployment or pause PCF VMs to make more capacity available. These actions can result in PCF downtime.

Recommended Starting Configuration

If you are running a PCF deployment as recommended by the base reference architecture for PCF on vSphere (recommended), then your vSphere installation should have the following components:

- One vCenter Server
- Three ESXi hosts per cluster
- Three or more clusters
- One (or HA pair) NSX Edge appliances

 **Note:** Pivotal recommends having at least three ESXi hosts in your cluster to maintain PCF high availability during your upgrade.

For more information, see the [Reference Architecture for Pivotal Cloud Foundry on vSphere](#).

Procedure to Upgrade vSphere

To upgrade the vSphere management layer underneath PCF, perform the following steps:

Step 1. Upgrade vCenter

For example, you might be upgrading vCenter 6.0 to vCenter 6.5.

For more information about how to upgrade vCenter, see [Overview of the vCenter Server Upgrade Process](#)  in VMware documentation.

Step 2. Upgrade ESXi Hosts

After a successful vCenter upgrade, upgrade your ESXi hosts one at a time.

Starting with the first ESXi host, perform the following steps:

1. Verify that your ESXi hosts have sufficient resources and headroom to evacuate the VM workload of a single ESXi host to the two remaining hosts.

 **Note:** If you have enabled vSphere HA on your ESXi host, then each ESXi host should have sufficient headroom capacity since HA reserves 66% of available memory.

2. Use vMotion to move all the PCF VMs on the host you want to upgrade to the other ESXi hosts. vMotion places the VMs on the other hosts based on available capacity. For more information, see [Migration with vMotion](#) in VMware documentation.
3. Upgrade the evacuated ESXi host. For example, you may be upgrading from ESXi v6.0 to ESX v6.5. For instructions, see [Upgrading ESXi Hosts](#) in VMware documentation.

After successfully upgrading the first ESXi host, repeat the above steps for each remaining host one at a time. vSphere automatically rebalances all PCF VMs back onto the upgraded hosts via DRS after all the hosts are done.

Step 3. Upgrade ESG on VMware NSX

If your PCF deployment lives on a network behind an Edge Services Gateway (ESG) as recommended by the reference architecture, then upgrade each ESG only after completing the upgrade of vCenter and your ESXi hosts.

When you upgrade an ESG on VMware NSX, you upgrade the NSX Manager software. This upgrade can cause some slight downtime, the amount of which depends on the number of ESGs you are using.

- If your deployment only has one ESG, you can expect a downtime of 5 minutes for network reconvergence.
- If your ESGs are deployed in HA, upgrade the first ESG. Then upgrade the second ESG. This upgrade results only in 15-20 seconds of downtime.

For more information, see the [NSX Upgrade Guide](#) in VMware documentation.

Migrating PCF to a New Datastore in vSphere

Page last updated:

This topic describes how to migrate your Pivotal Cloud Foundry (PCF) installation to a new vSphere datastore.

Prerequisites

Both the new and existing vSphere datastores must reside in the same datacenter.

To avoid service disruption, Pivotal recommends that you configure your overall PCF deployment for [high availability](#). In addition, check for configurations necessary to achieve high availability in each of your installed product tiles.

If your environment has any single points of failure, service may be disrupted as a result of the migration.

Before You Begin

This section describes the steps you should perform prior to the migration.

Step 1: Back Up Your Environment

Ensure that your PCF environment is fully backed up.

For more information about how to backup PCF, see [Backing up Pivotal Cloud Foundry](#).

Step 2: Document Current Environment Settings

Document your current environment settings before proceeding with the datastore migration. Record which VMs are running and in which datastore they reside. If you experience any issues during or after the migration, you must have this information to restore your environment.

To obtain this information, perform the following steps:

1. Run the `bosh instances` command.
 - If you use [BOSH CLI v2+](#), run the following command, replacing `MY-ENV` with the alias you assigned to your BOSH Director:

```
$ bosh -e MY-ENV instances --details > instances.txt
```

- If you use the original version of the BOSH CLI, run the following command:

```
$ bosh-old instances --details > instances.txt
```

2. Save the resulting file `instances.txt` to a safe location.
3. Note the datastore where each VM resides in vSphere.

Step 3: Check System Health

In Pivotal Application Service (PAS), check the **Status** tab and make sure there are no errors or reported issues.

Step 4: Check Installed Products Health

In each tile installed in your PCF deployment, check the **Status** tab and make sure there are no errors or reported issues.

Step 5: Check BOSH Director Status

1. Check that there are no pending changes and that the status of all tiles is green.
2. Make sure the last Installation Log does not contain any errors.
3. Before proceeding with the migration, click **Apply Changes** to make sure there are no errors in the Installation Log.

Procedure: Migrate PCF to a New Datastore

1. In BOSH Director, navigate to the **vCenter Config** page.
2. Update the **Ephemeral Datastore Names** and **Persistent Datastore Names** field to reflect the new datastore names, then click **Save**.

Note: If you use the Datastore Clustering feature in vSphere, provide only the individual names of the datastores in the cluster. Do not provide the name of the cluster that contains them.

3. Click **Apply Changes**.
4. Confirm that the BOSH Director VM has persistent disk on the new datastore.
 - a. Navigate to **vCenter Resource Pools** and select the **Resource Pool** that contains your PCF deployment VMs and new datastore.
 - b. Click the **Related Objects** and **Virtual Machines**.
 - c. Locate the Ops Manager VM and verify that the VM has an expected value in the **Provisioned Space** column.

5. In BOSH Director, navigate to the **Director Config** page, and select the **Recreate all VMs** option.
6. Click **Apply Changes**.

After the Migration

When BOSH moves disks, it waits for up to 60 minutes for the operation to complete. If the operation does not complete in time, BOSH can enter a state where it claims that the disks are `out of sync`.

Fix Failed BOSH Deployment with Out-of-Sync Error

If your PCF deployment gets into this state, you can resolve the issue by performing the steps in the KB article [How to recover from a failed bosh deployment when VMs are out of sync on vSphere](#).

Prevent Out-of-Sync Error

You can also prevent the `out of sync` BOSH error by increasing the CPI timeout to a larger value before performing the migration. Follow the instructions in the KB article [How to Increase the Timeout on Bosh CPI Command Calls](#).

Control Plane Reference Architectures

Introduction

Concourse is the main continuous integration and continuous delivery (CI/CD) tool that the Pivotal and open-source Cloud Foundry communities use to develop, test, deploy and manage Cloud Foundry foundations.

This topic describes topologies and best practices for deploying Concourse on [BOSH](#), and using Concourse to manage Pivotal Cloud Foundry (PCF) foundations. For production environments, Pivotal recommends deploying Concourse with BOSH.

The three topologies described in this document govern the network placement and relationship between two systems:

- The **control plane** runs Concourse to gather sources for, integrate, update, and otherwise manage PCF foundations. This layer may also host internal Docker registries, S3 buckets, git repositories, and other tools.
- Each **PCF foundation** runs PCF on an instance of BOSH.

Each topology described below has been developed and validated in multiple PCF customer and Pivotal Labs environments.

Deployment Topologies

Security policies are usually the main factor that determines which CI/CD deployment topology best suits a site's needs. Specifically, the decision depends on what network connections are allowed between the control plane and the PCF foundations that it manages.

The following three topologies answer a range of security needs, ordered by increasing level of security around the PCF foundations:

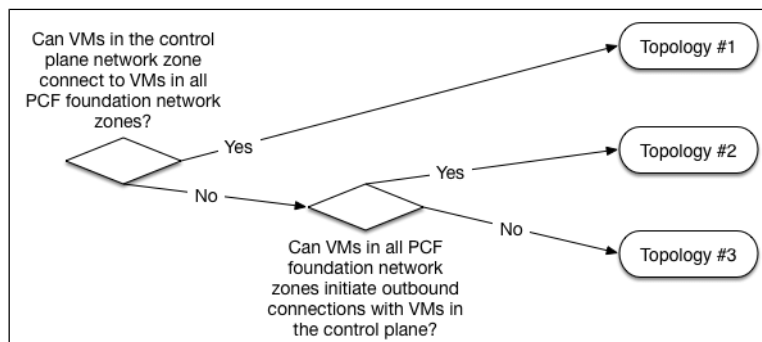

- [Topology 1](#): Concourse server and worker VMs all colocated on control plane
- [Topology 2](#): Concourse server on control plane, and remote workers colocated with PCF foundations
- [Topology 3](#): Multiple Concourse servers and workers colocated with PCF foundations

Across these three topologies, the increasing level of PCF foundation security correlates with:

- Increasing network complexity
- Increasing effort required for initial deployment and ongoing maintenance

Security Decision Factors

The graph below captures the decision factors dictated by network security policy, and recommends Concourse deployment topologies that adhere to those policies.

Additional Decision Factors

In addition to security policy, deciding on a CI/CD deployment topology may also depend on factors such as:

- Network latency across network zones

- Air-gapped vs. Internet-connected environments
- Resource limitations

The [Credentials Management](#) and [Storage Services](#) sections below includes notes and recommendations regarding credentials management, Docker registries, S3 buckets, and git repositories, but does not cover these tools extensively.

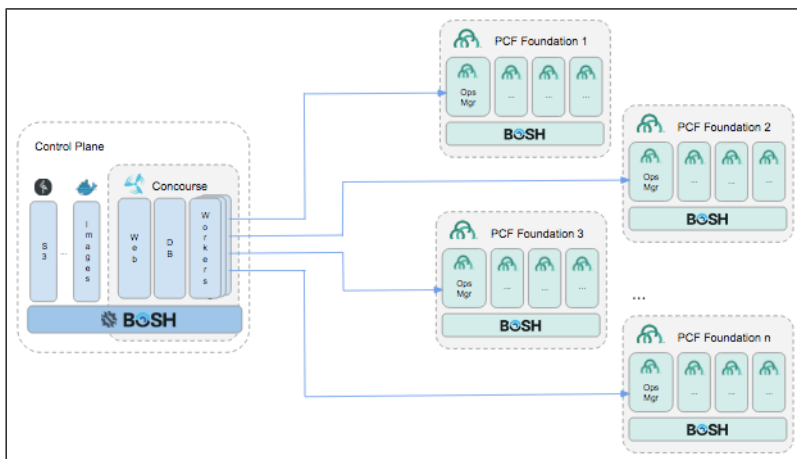

Topology Objects

Complete deployment topologies dictate the internal placement or remote use of the following:

- Concourse server and worker VMs, as discussed [above](#)
- Credentials managers such as CredHub or Vault
- Docker registries, public or private
- S3 or other storage buckets, public or private
- git or other code repositories, public or private

Topology 1: Concourse Server and Worker VMs All Colocated on Control Plane

This simple topology follows network security policies that allow a single control plane to connect to all PCF foundations deployed across multiple network zones or data centers.

In this topology, the Concourse server and worker VMs, along with other tools (e.g. Docker registry, S3 buckets, Vault server), are all deployed to the same subnet.

Connectivity Requirements

Concourse worker VMs must be allowed to connect to:

- The Ops Manager VM or a jumpbox VM in all of the PCF foundations networks
- (on vSphere) The vCenter API for each PCF foundation

Performance Notes

Network data transfers between the control plane and each PCF foundation network zone may carry large files such as PCF tiles, release files, and PCF foundation backup pipelines output.

Pivotal recommends that you test network throughput and latency between those network zones to make sure that data transfer rates do not make pipeline execution times unacceptably long.

Firewall Requirements

All Concourse worker VMs are required to connect to certain VMs on PCF foundation subnets across networks zones or data centers.

See [PCF CI/CD Pipelines](#) section for required VMs, ports, and external websites required for PCF CI/CD pipelines.

Pros

- Simplified deployment and maintenance of centralized control plane, which requires only one BOSH deployment and runs one BOSH Director.
- Simplified setup and maintenance of PCF CI/CD pipelines. All pipelines and Concourse teams use a single, centralized server.

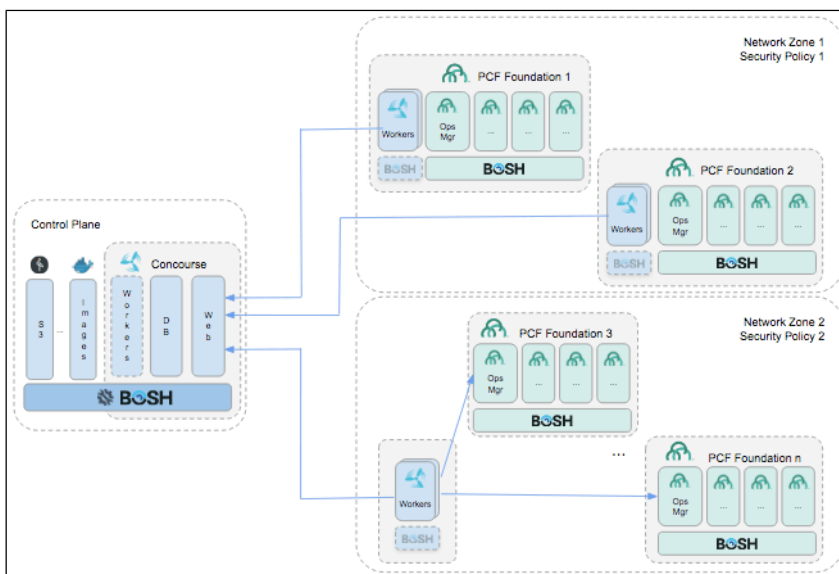

Cons

- You may have to configure firewall rules in each PCF network to allow connectivity from workers in CI/CD zone, as mentioned above.

Topology 2: Concourse Server on Control Plane, and Remote Workers Colocated with PCF Foundations

This topology supports environments where PCF foundation VMs cannot receive incoming traffic from IP addresses outside their network zone or data center, but they can initiate outbound connections to outside zones.

As in [Topology 1](#), the Concourse server, and potentially other VMs for tools such as Docker registries or S3 buckets, are deployed to a dedicated subnet. The difference here is that Concourse worker VM pools are deployed inside each PCF foundation subnet, network zone, or data center.

Connectivity Requirements

Concourse worker VMs in each PCF foundation network zone or data center must:

- Connect to the Ops Manager VM or a jumpbox VM in each PCF foundations network
- (on vSphere) Connect to the vCenter API for each PCF foundation
- Have outbound connection access to the Concourse web/ATC server on port 2222. This lets them handshake with the Concourse server to open a reverse SSH tunnel for ongoing communication between them and the Concourse ATC.

For more details, see [Concourse Architecture](#).

Performance Notes

Remote workers have to download large installation files from either the Internet or from a configured S3 artifacts repository. For PCF backup pipelines, workers may also have to upload large backup files to the S3 repository.

Pivotal recommends that you test network throughput and latency between those network zones to make sure that data transfer rates do not make pipeline execution times unacceptably long.

Firewall Requirements

Remote worker VMs require outbound access to the Concourse web/ATC server on port 2222.

Remote worker VMs inside each PCF foundation network zone or data center are required to connect to VMs in their colocated foundation. They may also require access to external web sites or S3 repositories for downloading installation files.

See the [PCF CI/CD Pipelines](#) section for required VMs and ports required for PCF CI/CD pipelines.

Pros

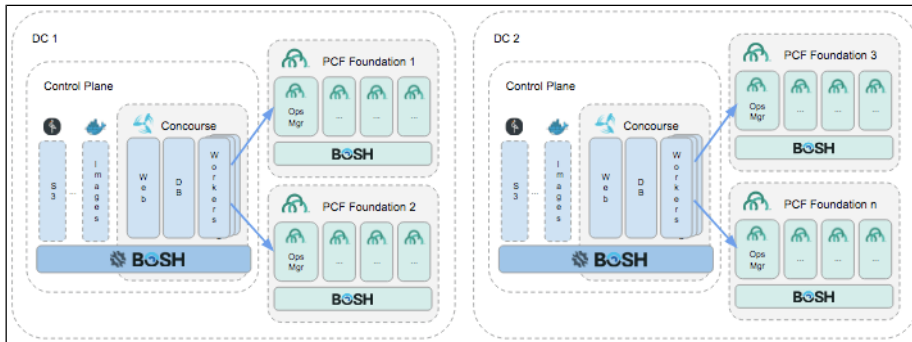

- Relatively simple maintenance of centralized control plane, which contains single Concourse server and other tools.
- Simplified setup and maintenance of PCF CI/CD pipelines. All pipelines and Concourse teams use a single, centralized server.

Cons

- You have to reconfigure firewalls to grant outbound access to remote worker VMs.
- In addition to deploying the control plane, you need an additional BOSH deployment and running BOSH Director for each PCF Foundation network zone or data center.
- You need to manage multiple Concourse worker pools in multiple locations.

Topology 3: Multiple Concourse Servers and Workers Colocated with PCF Foundations

This topology supports environments where PCF foundation VMs can only be accessed from within the same network zone or data center. This scenario requires deploying complete and dedicated control planes within each deployment zone.

Performance Notes

Since workers run in the same network zone or data center as the PCF foundation, data transfer throughput should not limit pipeline performance.

Firewall Requirements

- **Air-gapped environments** require some way to bootstrap S3 repository with Docker images and PCF releases files for pipelines from external sites.
- **Non-air-gapped environments**, in which workers can download required files from external websites, need those websites to be whitelisted in the proxy or firewall setup.

Pros

- Requires little or no firewall rules configuration for control plane VMs. In non-air-gapped environments, worker VMs download PCF releases and Docker images for pipelines from external websites.

Cons

- Requires deploying and maintaining multiple Concourse and other tools.
- Requires deploying and maintaining multiple PCF pipelines for each Concourse server.
- For air-gapped environments, requires setting up an S3 repository for each control plane.

Deploying CI/CD to the Control Plane

There are a few alternatives to deploy BOSH Directors, Concourse servers, and other tool releases to the control plane. Details on those alternatives are outside of the scope of this document, but refer to the links below for the most common options:

Manual deployments

- BOSH Director: [BOSH create-env](#)
- Concourse
 - [Concourse](#)
 - [Concourse with CredHub](#)
 - [Concourse with Vault](#)

- Docker registries
 - [Private Docker Registry](#)
 - [VMware Harbor Registry](#)
- S3 buckets
 - [Minio S3](#)
 - [EMC Cloud Storage](#)

Automated deployments

- [Bosh Bootloader \(BBL\)](#) deploys BOSH Director and Concourse on multiple IaaS.

Control Plane Deployment Best Practices

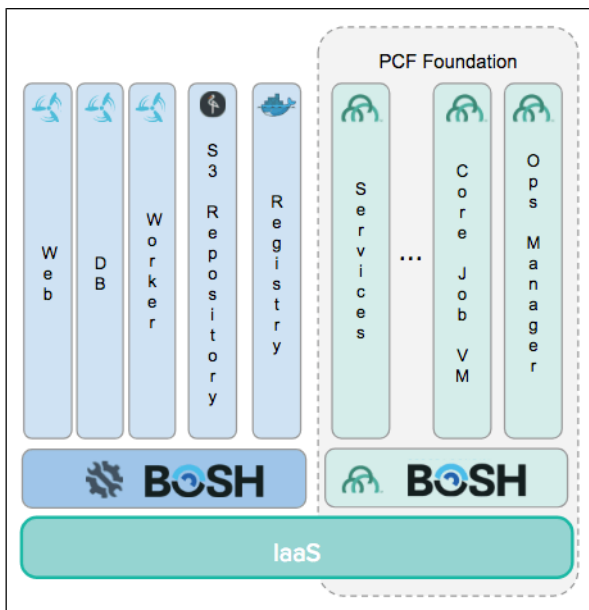

Here are some best practices for control plane components that apply across all deployment topologies:

Dedicated BOSH Director

Pivotal recommends deploying Concourse and other control plane tools on their own, dedicated BOSH layer, with their own BOSH Director that runs separately from the PCF foundations that the control plane manages.

Pivotal does **not** recommend using an existing PCF BOSH Director instance to deploy Concourse and other software (e.g. Minio S3, private Docker registry, CredHub). Sharing the same BOSH Director with PCF deployments increases the risk of accidental or undesired updates or deletion of those deployments.

Dedicating a BOSH Director to Concourse and other control plane tools also provides higher flexibility for PCF foundation upgrades and updates, such as stemcell patches.

Credentials Management

All credentials and other sensitive information that feeds into a Concourse pipeline should be encrypted and stored using credentials management software such as CredHub or Vault. Never store credentials as plain text in parameter files in file repositories.

Credentials Management with CredHub

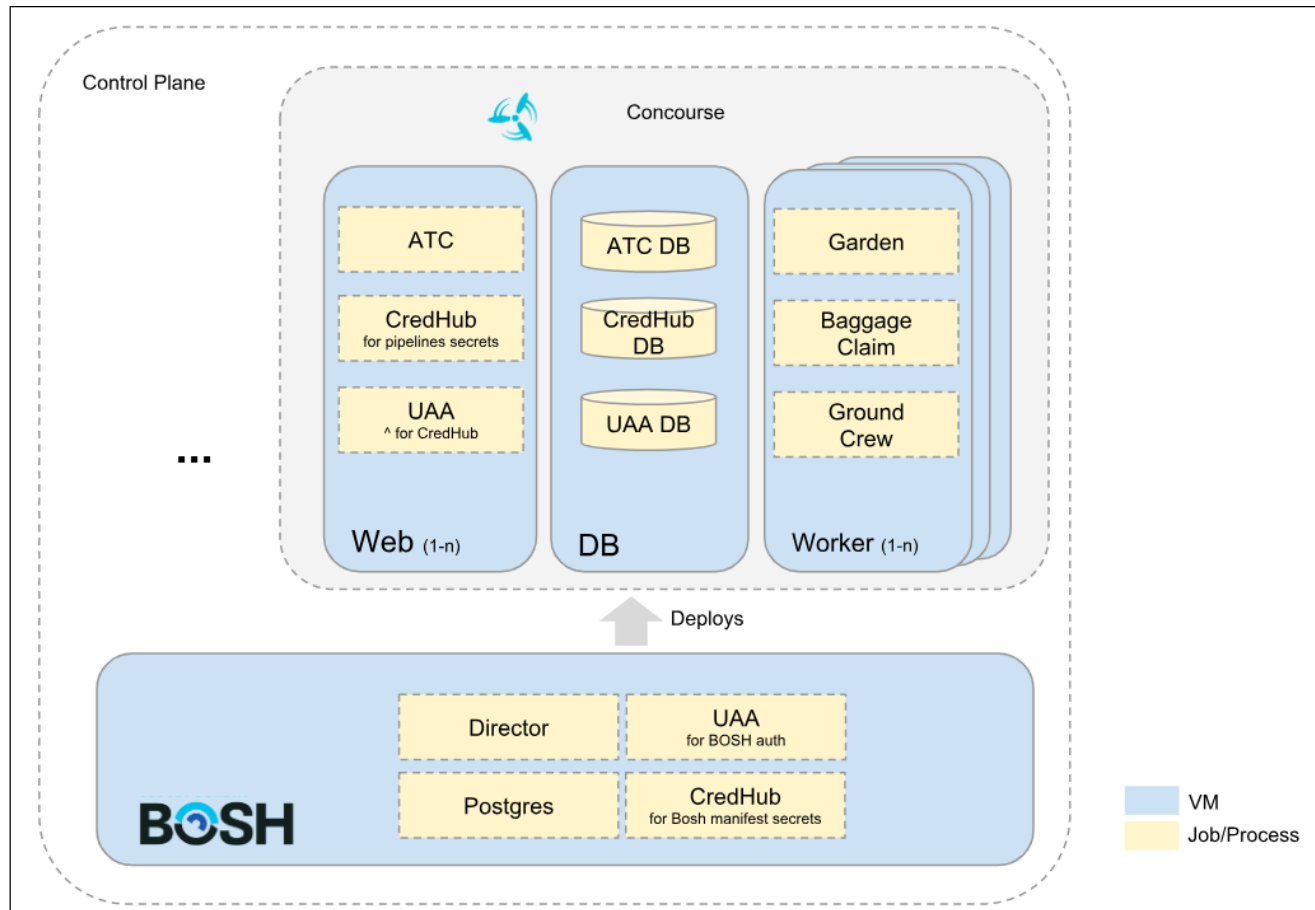

Concourse integrates with CredHub to manage credentials in its pipelines. The pipelines reference encrypted secrets stored in a CredHub server and retrieve them automatically during execution of tasks.

To integrate Concourse with a CredHub server, you configure its ATC job's deployment properties with information about the CredHub server and corresponding UAA authentication credentials.

You can deploy CredHub in multiple ways: as a dedicated VM, or integrated with other VMs, such as colocating the CredHub server with the BOSH Director VM or Concourse's ATC/web VM.

Colocating a CredHub server with Concourse's ATC VM dedicates it to the Concourse pipelines and lets Concourse administrators manage the credentials server. This configuration also means that during Concourse upgrades, the CredHub server only goes down when the Concourse ATC job is also down, which minimizes potential credential server outages for running pipelines.

The diagram below illustrates the jobs of Concourse VMs, along with the ones for the BOSH Director VM, when a dedicated CredHub server is deployed with Concourse.

The [Concourse Pipelines Integration with CredHub](#) documentation in the PCF Pipelines repository describes how to deploy a CredHub server integrated with Concourse.

Credentials Management with Vault

For how to configure Vault to manage credentials for Concourse pipelines, see [Secure credential automation with Vault and Concourse](#) in the PCF Pipelines repository.

Storage Services

Git Server

BOSH and Concourse implement the concepts of infrastructure-as-code and pipelines-as-code. As such, it is important to store all source code for deployments and pipelines in a version-controlled repository.

PCF CI/CD pipelines assume that their source code is kept in git-compatible repositories. [GitHub](#) is the most popular git-compatible repository for Internet-connected environments.

GitLab, BitBucket and [GOGS](#) are examples of git servers that can be used for both connected and air-gapped environments.

A git server that contains configuration and pipeline code for a PCF foundation needs to be accessible by the corresponding worker VMs that run CI/CD pipelines for that foundation.

S3 Repository

In all environments Concourse requires an S3 repository to store PCF backups and possibly other files. If your deployment requires a private, internal S3 repository but your IaaS lacks built-in options, you can use BOSH to deploy your own S3 releases, such as [Minio S3](#) and [EMC Cloud Storage](#) to your control plane.

For air-gapped environments, an S3 repository is also the preferred method to store release files for PCF tiles, stemcells and buildpacks. Docker images can also be stored to an S3 repository as an alternative to a private Docker registry. See [Offline Pipelines for Airgapped Environments](#) for details.

Private Docker Registry

For air-gapped environments, Docker Images for Concourse pipelines need to be stored either on a private Docker registry or in an S3 repository. For BOSH-deployed private registry alternatives, check [Docker Registry](#) or [VMWare Harbor](#).

High Availability

For details on how to set up a load balancer to handle traffic across multiple instances of the ATC/web VM, and how to deploy multiple worker instances, see the [Concourse Architecture](#) topic.

PCF CI/CD Pipelines

PCF Pipelines

PCF Platform Automation with Concourse (PCF Pipelines) is a collection of Concourse pipelines for installing and upgrading Pivotal Cloud Foundry. See the [source on Github](#) or download from [Pivotal Network](#) (sign-in required).

 **warning:** At time of publication, the PCF Pipelines repository is undergoing planned deprecation.

To run PCF Pipelines, you need:

- Ops Manager web UI, API and VM installed
- (vSphere environments) vCenter API installed
- For proxy- or Internet-connected environments, whitelist the following sites:
 - [Docker Hub](#): hub.docker.io
 - [Pivotal Network](#): network.pivotal.io
 - bosh.io

BOSH Backup and Restore (BBR) PCF Pipelines

BBR PCF Pipelines automate PCF foundation backups. See and download the [source on Github](#).

To run BBR PCF Pipelines, you need an S3 repository for storing backup artifacts.

 **Note:** BBR PCF Pipelines is a PCF community project not officially supported by Pivotal.

Pipelines Orchestration Frameworks

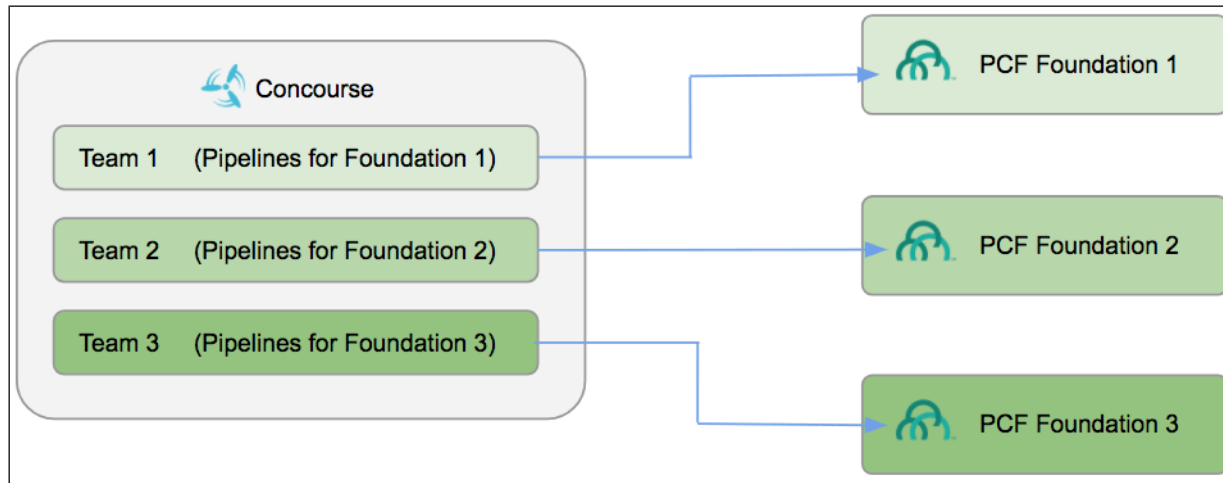

[PCF Pipelines Maestro](#) uses a Maestro framework to:

- Automate pipeline creation and management for multiple PCF foundations
- Promote and audit configuration changes and version upgrades across all foundations

 **Note:** PCF Pipelines Maestro is a PCF community project not officially supported by Pivotal.

Concourse Team Management Best Practices

When a single Concourse server hosts CI/CD pipelines for more than one PCF foundation, Pivotal recommends creating one Concourse team (not `main`) specific to each foundation, and associating that team with all pipelines for that foundation, e.g. install, upgrade, backup, and metering.

Dedicating a Concourse team to each PCF foundation has the following benefits:

- **It avoids the clutter of pipelines in a single team.** The list of pipelines for each foundation may be long, depending how many tiles are deployed to it.
- **It avoids the risk of operators running a pipeline for the wrong foundation.** When a single team hosts maintenance pipelines for multiple foundations, the clutter of dozens of pipelines may lead operators to accidentally run a pipeline (e.g. upgrade or delete tile) targeted at the wrong PCF foundation.
- **It allows for more granular access control settings per team.** PCF pipelines for higher environments (e.g. Production) may require a more restricted access control than ones from lower environments (e.g. Sandbox). Authentication settings for Concourse teams enable that level of control.
- **It allows workers to be assigned to pipelines of a specific foundation.** Concourse deployment configuration allows for the assignment of workers to a single team. If that team contains pipelines of only one foundation, then the corresponding group of workers run pipelines only for that foundation. This is useful when security policy requires tooling and automation for a foundation (e.g. Production) to run on specific VMs.

Concourse Teams for App Development Orgs and Spaces

When a Concourse server hosts pipelines for an app development team, Pivotal recommends creating a Concourse team associated with that development team, and associating Concourse team membership with org and space membership defined in the Pivotal Application Service (PAS) user authentication and authorization (UAA) server.

Associating Concourse teams with PAS org and space member lists synchronizes access between PAS and Concourse, letting developers see and operate the build pipelines for the apps they develop.

Implementing a Multi-Foundation PKS Deployment

Page last updated:

This topic describes how to deploy multiple instances of PKS on vSphere with NSX-T infrastructure.

About Multi-Foundation PKS

A multi-foundation deployment of PKS lets you install and run multiple instances of PKS. The purpose of a multi-foundation deployment of PKS is to share a common vSphere and NSX-T infrastructure across multiple foundations, while providing complete networking isolation across foundations.

As shown in the diagram, with a multi-foundation PKS topology, each PKS instance is deployed to a dedicated NSX-T Tier-0 router. Foundation A T0 router with Management CIDR 10.0.0.0/16 connects to the vSphere and NSX-T infrastructure. Similarly, Foundation B T0 router with Management CIDR 20.0.0.0/16 connects to the same vSphere and NSX-T components.

As with a single instance deployment, PKS management components are deployed to a dedicated network, for example, 10.0.0.0/24 for PKS Foundation A; 20.0.0.0/24 for PKS Foundation B. When PKS is deployed, networks are defined for nodes, pods, and load balancers. Because of the dedicated Tier-0 router, there is complete networking isolation between each PKS instance.

Requirements

To implement a multi-foundation PKS topology, adhere to the following requirements:

- One Tier-0 router for each PKS instance. For more information, see [Configuring Multiple Tier-0 Routers for Tenant Isolation](#).
- The Floating IP pool must not overlap. The CIDR range for each Floating IP Pool must be unique and not overlapping across foundations. For more information, see [Create Floating IP Pool](#).
- PKS instances can be deployed in NAT and no-NAT mode. If more than one PKS instance is deployed in no-NAT mode, the Nodes IP Block networks cannot overlap.
- For any Pods IP Block used to deploy Kubernetes clusters in no-NAT (routable) mode, the Pods IP Block cannot overlap across foundations.

The image below shows three PKS installations across three Tier-0 foundations. Key considerations to keep in mind with a multi-foundation PKS topology include the following:

- Each foundation must rely on a dedicated Tier-0 router

- You can mix-and-match NAT and no-NAT mode across foundations for Node and Pod networks
- If you are using non-routable Pods IP Block networks, the Pods IP Block addresses can overlap across foundations
- Because Kubernetes nodes are behind a dedicated Tier-0 router, if clusters are deployed in NAT mode the Nodes IP Block addresses can also overlap across foundations
- For each foundation you must define a unique Floating ID Pool with non-overlapping IPs

| PKS Foundation A | | PKS Foundation B | PKS Foundation C |
|--|----------------------------|--------------------------------------|---------------------------------------|
| <input checked="" type="checkbox"/> NAT mode | Can mix modes | <input type="checkbox"/> NAT mode | <input type="checkbox"/> NAT mode |
| Pods IP Block ID * | Must be unique if routable | Pods IP Block ID * | Pods IP Block ID * |
| 927a2eff-fa86-4df8-bb21-c45b5314f547 | | 927a2eff-fa86-4df8-bb21-c45b5314f547 | 1b81b967-a269-4a62-9ff5-e2a39a5feaae |
| Nodes IP Block ID * | Can overlap | Nodes IP Block ID * | Nodes IP Block ID * |
| 3d577e5c-acaf-4921-9458-a12b0e1318e6 | | 3d577e5c-acaf-4921-9458-a12b0e1318e6 | 3d577e5c-acaf-4921-9458-a12b0e1318e6 |
| T0 Router ID * | Must be unique | T0 Router ID * | T0 Router ID * |
| 40445803-8c3c-417e-bb24-a84cf9d330b5 | | 5c579e37-5318-4255-9658-1a2e99e1d1e9 | 791f220b-155b-4fe9-bf3b-58199e4ea911d |
| Floating IP Pool ID * | Must be unique | Floating IP Pool ID * | Floating IP Pool ID * |

| vSphere Cluster Names * | Should be unique | vSphere Cluster Names * | vSphere Cluster Names * |
| Cluster-A | | Cluster-B | Cluster-C |

Please send any feedback you have to pbs-feedback@pivotal.io.

Global DNS Load Balancers for Multi-Foundation Environments

This topic describes global DNS load balancers (GLBs) for multi-foundation environments. This topic also describes concepts such as foundation affinity and healthchecks.

 **Note:** If you want to configure a load balancer dedicated to one PCF foundation and you are using an F5 LTM, see [Configuring an F5 Load Balancer for PAS](#) .

About Multi-Foundation Environments

Multi-foundation environments are multiple instances of BOSH and Ops Manager that can communicate with each other. Each foundation can use different infrastructures to fit your preferences.

Multi-foundation environments are commonly deployed in an active-active or active-passive pattern. See below for descriptions of each term:

| Term | Description |
|------------------------|--|
| Active-active pattern | Instances of apps run on two foundations and they are both in use. |
| Active-passive pattern | Instances of apps run on two foundations, but the instances may only be active on one foundation. The other foundation becomes active only in the event of a failover. |

Configure Your GLB

The typical setup for foundation failover requires the GLB be authoritative for a wildcard app domain. The wildcard app domain is not the same domain as the foundation-default app domain.

To configure your GLB, do the following:

- Find and record your wildcard app domain. For Pivotal Application Service (PAS), your wildcard app domain is typically the **Apps Domain** you configure in the **Domains** pane of the PAS tile.
- Add the domain you recorded to both PCF foundations using a shared domain. You can create a shared domain using the Cloud Foundry Command Line Interface (cf CLI). For more information about the cf CLI command to create shared domains, see [create-shared-domain](#)  in the cf CLI reference guide.
- To support failover, set the time-to-live (TTL) in the wildcard DNS record. Set the TTL to about 30 to 180 seconds. When determining your TTL, consider the tradeoff between the app performance impact and the resulting time for failover to occur.

About Foundation Affinity

Foundation affinity occurs when the GLB favors one foundation over another during a route request. For example, users experience less latency if they are routed to a foundation that is geographically closer, so the GLB may favor that foundation.

Different GLBs have their own mechanisms to achieve this. See the following table for common concepts:

| Foundation Affinity Concepts | |
|--|--|
| Term | Description |
| Topology/geographically-based affinity | The GLB attempts to direct traffic to the graphically nearest foundation based on IP geolocation or provided topology for private networks of the LDNS server performing the lookup. |
| Static-persist/member-hashing affinity | The GLB attempts to direct traffic to the graphically nearest foundation based on IP geolocation or provided topology for private networks of the LDNS server performing the lookup. |
| Active/passive foundations | If one foundation is usually idle, you can always pick the active foundation IP as long as it remains available. |
| Microservice-to-microservice affinity | For microservice apps, you typically use a Services Registry to manage traffic between microservices. There are two ways to do this: <ul style="list-style-type: none"> If the microservices are using the domain which maps to the GLB, then their traffic is routed through the GLB. If the microservices are communicating using IP address or internal domains, such as when using Envoy, then the |

traffic does not pass through the GLB.

About Healthchecks

Healthchecks determine whether a foundation for an app is healthy or not.

See the following table for the levels at which you can check the health of your foundation:

| Level | Description |
|------------|--|
| Foundation | GLB relies on a local load balancer in front of the PCF Gorouters to determine the overall health of the foundation. GLB can perform healthchecks on TCP port 443 or 80 or on the local load balancer. The local load balancer healthchecks the backend pool of Gorouters on port 8080. |
| App | Healthchecks are set only for apps which have instances on both foundations. Each app instance has canary DNS records. The canary DNS records are the same for the app instances on each foundation. You would also need to add more VIPs dedicated to these canary apps that would be used to check their health. |

⚠ warning Pivotal does not recommend setting healthchecks at the app level. Configuring healthchecks in this way can cause more frequent failover and delays while pushing apps. Complete failover of a foundation affects all apps on the platform. Healthchecks on a per-app basis can require additional overhead beyond the control of an app developer.

Architecture and Installation Overview

For PCF Architects and Operators

This guide shows you how to design a Pivotal Cloud Foundry (PCF) platform and install it on an IaaS. If you are doing this, you have one or both of the following roles:

- **Architects** design a PCF platform. They know the IaaS that they will deploy it to, and what other relevant resources they have. In their design, they consider needs for the platform's capacity, availability, security, geography, budget, and other factors. If they do not install PCF themselves, they provide the architectural specifications to whoever does.
- **Operators** run a PCF platform, keep it up-to-date, monitor its health and performance, and fix any problems. They may also install the platform, or perform "Day 2" configurations that expand its functionality and integrate it with external systems.

This guide helps people in both roles create a PCF platform that does what they want it to. The contents of this guide follow the phases of a typical PCF planning and installation effort.

 **Note:** Elastic Runtime has been renamed Pivotal Application Service.

Planning and Installation Overview

PCF is a suite of products that runs on multiple IaaS. Planning and installing PCF means building layers from the bottom up, starting with the details of your IaaS and ending with "Day 2" configurations that you perform on a installed and running PCF deployment.

Here's the typical PCF planning and installation process:

1. Plan

- Review the Requirements for your IaaS ([AWS](#), [Azure](#), [GCP](#), [OpenStack](#), [vSphere](#)).
- Refer to the Reference Architecture for your IaaS.
- Assess your platform needs, including capacity, availability, container support, host OS, resource isolation, and geographical distribution. Discuss with your Pivotal contact.

2. Deploy BOSH and Ops Manager

- [BOSH](#)  is an open-source tool that lets you run software systems in the cloud.
 - BOSH and its IaaS-specific Cloud Provider Interfaces (CPIs) are what enable PCF to run on multiple IaaS.
 - See [Deploying with BOSH](#)  for a brief description of the BOSH deployment process.
- [Ops Manager](#) is a GUI application deployed by BOSH that streamlines deploying subsequent software to the cloud via BOSH.
 - Ops Manager represents PCF products as *tiles* with multiple configuration panes that let you input or select configuration values needed for the product.
 - Ops Manager generates BOSH manifests containing the user-supplied configuration values, and sends them to the Director.
 - After you install Ops Manager and BOSH, you use Ops Manager to deploy almost all PCF products.
- Deploying Ops Manager deploys both BOSH and Ops Manager with a single procedure.
 - On AWS, you can deploy Ops Manager manually, or automatically with a CloudFormation template.
 - On Azure, you can deploy Ops Manager manually, or automatically with an Azure Resource Manager (ARM) template. On Azure Government Cloud and Azure Germany you can only deploy Ops Manager manually.

3. Deploy BOSH Add-ons (Optional)

- BOSH add-ons include the [IPsec](#) , [ClamAV](#) , and [File Integrity Monitoring](#) , which enhance PCF platform security and security logging.
- You deploy these add-ons via BOSH rather than installing them with Ops Manager tiles.

4. Install Runtimes

- [PAS](#)  (Pivotal Application Service) lets developers develop and manage cloud-native apps and software services.
 - PAS is based on the Cloud Foundry Foundation's open-source Application Runtime (formerly Elastic Runtime) project.
- [PKS](#)  (Pivotal Container Service) uses BOSH to run and manage Kubernetes container clusters.

- PKS is based on the Cloud Foundry Foundation’s open-source Container Runtime (formerly Kubo) project.
- [PCF Isolation Segment](#) lets a single PAS deployment run apps from separate, isolated pools of computing, routing, and logging resources.
 - Operators replicate and configure an Isolation Segment tile for each new resource pool they want to create.
 - You must install PAS before you can install Isolation Segment.
- [PAS for Windows 2012R2](#) enables PAS to manage Windows Server 2012 cells hosting .NET apps, and can also be replicated to create multiple isolated resource pools.
 - As with Isolation Segment, Operators replicate and configure a PAS for Windows 2012R2 tile for each new resource pool they want to create.
 - You must install PAS before you can install PAS for Windows 2012R2.
- [Small Footprint PAS](#) is an alternative to PAS that uses far fewer VMs than PAS but has limitations.

5. Install Services

- Install software services for PCF developers to use in their apps.
 - Services include the databases, caches, and message brokers that stateless cloud apps rely on to save information.
 - Installing and managing software services on PCF is an ongoing process, and is covered in the [PCF Operator Guide](#).

6. Day 2 Configurations

- Day 2 configurations set up internal operations and external integrations on a running PCF platform.
 - Examples include front-end configuration, user accounts, logging and monitoring, internal security, and container and stemcell images.

Guide Contents

This guide has two parts. The first part explains the PCF planning and installation process, and the second describes the main tools that operators use when installing PCF.

Planning and Installation

PCF is a suite of products that runs on multiple IaaS. Planning and installing PCF means building layers from the bottom up, starting with the details of your IaaS and ending with “Day 2” configurations that you perform on a installed and running PCF deployment.

This guide follows this bottom-up progression:

- [Planning PCF](#) - Design a PCF platform that runs on your IaaS and fits your needs.
- [Deploying BOSH and Ops Manager](#) - Build the foundation of PCF.
- [Deploying BOSH Add-Ons](#) - Use BOSH to extend foundation-level PCF capabilities.
- [Using Ops Manager](#) - Ops Manager provides a dashboard for installing and configuring PCF products and services.
- [Using the Cloud Foundry Command Line Interface \(cf CLI\)](#) - The cf CLI runs PCF operations in the cloud from a shell on your local workstation.
- [Installing Runtimes](#) - Install the application and container runtime environments that PCF exists for.
- [Installing Platform Extension Tiles](#) - Use Ops Manager to extend PCF platform capabilities.
- [Day 2 Configurations](#) - Set up internal operations and external integrations for PCF.
- [Troubleshooting and Diagnostics](#)

After installing PCF, Operators install the software services that PCF developers use in their apps. These PCF services include the databases, caches, and message brokers that stateless cloud apps rely on to save information.

Installing and managing software services on PCF is an ongoing process, and is covered in the [PCF Operator Guide](#).

Related Documentation

The [PCF Operator Guide](#) explains how to maintain a running PCF platform, including monitoring, tuning, troubleshooting, and upgrading.

The [PCF Security Guide](#) explains how PCF security systems work and how to keep your PCF platform secure.

[Getting Started with PCF](#) gives a high-level overview of how PCF works and explains how you can try a simple deployment on your own local machine.

See [Pivotal Cloud Foundry Documentation](#) for all PCF documentation.

Preparing Your Firewall

Page last updated:

This topic describes how to configure your firewall for [Pivotal Cloud Foundry](#) (PCF) and how to verify that PCF resolves DNS entries behind your firewall.

Configure Your Firewall for PCF

Ops Manager and Pivotal Application Service (PAS) require the following open TCP ports:

- **25555**: Routes from Ops Manager to the BOSH Director.
- **443**: Routes to HAProxy or, if configured, your own load balancer.
- **80**: Routes to HAProxy or, if configured, your own load balancer.
- **8844**: Routes from Ops Manager to BOSH CredHub.
- **8443**: Routes from Ops Manager to BOSH Director UAA.
- **6868**: Routes to the BOSH Agent.
- **2222**: Necessary for using Application SSH. For details, see the [Diego Architecture Diagram](#).
- **25595**: Routes from the Traffic Controller to the BOSH Director, to enable sending BOSH health metrics to the Firehose.

UDP port **123** must be open if you want to use an external NTP server.

For more information about required ports for additional installed products, see [Network Communication Paths](#).

Example: Configure Firewall with iptables

The following example procedure uses `iptables` commands to configure a firewall.

Note: `GATEWAY_EXTERNAL_IP` is a placeholder. Replace this value with your `PUBLIC_IP`.

1. Open `/etc/sysctl.conf`, a file that contains configurations for Linux kernel settings, with the command below:

```
$ sudo vi /etc/sysctl.conf
```

2. Add the line `net.ipv4.ip_forward=1` to `/etc/sysctl.conf` and save the file.
3. If you want to remove all existing filtering or Network Address Translation (NAT) rules, run the following commands:

```
$ iptables --flush
$ iptables --flush -t nat
```

4. Add environment variables to use when creating the IP rules:

```
$ export INTERNAL_NETWORK_RANGE=10.0.0.0/8
$ export GATEWAY_INTERNAL_IP=10.0.0.1
$ export GATEWAY_EXTERNAL_IP=203.0.113.242
$ export PIVOTALCF_IP=10.0.0.2
$ export HA_PROXY_IP=10.0.0.254
```

5. Run the following commands to configure IP rules for the specified chains:

- **FORWARD:**

```
$ iptables -A FORWARD -i eth1 -j ACCEPT
$ iptables -A FORWARD -o eth1 -j ACCEPT
```

- **POSTROUTING:**

```
$ iptables -t nat -A POSTROUTING -o eth0 -j MASQUERADE
$ iptables -t nat -A POSTROUTING -d $SHA_PROXY_IP -s $INTERNAL_NETWORK_RANGE \
  -p tcp --dport 80 -j SNAT --to $GATEWAY_INTERNAL_IP
$ iptables -t nat -A POSTROUTING -d $SHA_PROXY_IP -s $INTERNAL_NETWORK_RANGE \
  -p tcp --dport 443 -j SNAT --to $GATEWAY_INTERNAL_IP
```

◦ PREROUTING:

```
$ iptables -t nat -A PREROUTING -d $GATEWAY_EXTERNAL_IP -p tcp --dport \
  25555 -j DNAT --to $PIVOTALCF_IP
$ iptables -t nat -A PREROUTING -d $GATEWAY_EXTERNAL_IP -p tcp --dport \
  443 -j DNAT --to $SHA_PROXY_IP
$ iptables -t nat -A PREROUTING -d $GATEWAY_EXTERNAL_IP -p tcp --dport \
  80 -j DNAT --to $SHA_PROXY_IP
$ iptables -t nat -A PREROUTING -i eth0 -p tcp --dport 8443 -j DNAT \
  --to $PIVOTALCF_IP:443
$ iptables -t nat -A PREROUTING -i eth0 -p tcp --dport 80 -j DNAT \
  --to $SHA_PROXY_IP:80
$ iptables -t nat -A PREROUTING -i eth0 -p tcp --dport 8022 -j DNAT \
  --to $PIVOTALCF_IP:22
$ iptables -t nat -A PREROUTING -i eth0 -p tcp --dport 8080 -j DNAT \
  --to $PIVOTALCF_IP:80
```

6. Run the following command to save the iptables:

```
$ service iptables save
```

For more information about administering IP tables with `iptables`, refer to the [iptables documentation](#).

Verify PCF Resolves DNS Entries Behind a Firewall

When you install PCF in an environment that uses a strong firewall, the firewall might block DNS resolution. For example, if you use [xip.io](#) to test your DNS configuration, the tests will fail without warning if the firewall prevents PAS from accessing `*.xip.io`.

To verify that PAS can correctly resolve DNS entries:

1. SSH into the Pivotal Ops Manager VM. For more information, refer to the [SSH into Ops Manager](#) section of the Advanced Troubleshooting with the BOSH CLI topic.
2. Run any of the following network administration commands with the IP address of the VM:
 - `nslookup`
 - `dig`
 - `host`
 - The appropriate `traceroute` command for your OS
3. Review the output of the command and fix any blocked routes. If the output displays an error message, review the firewall logs to determine which blocked route or routes you need to clear.
4. Repeat steps 1-3 with the BOSH Director VM and the HAProxy VM.

IaaS Permissions Guidelines

This topic describes practices recommended by Pivotal for creating secure IaaS user roles.

Pivotal Cloud Foundry (PCF) is an automated platform that connects to IaaS providers such as AWS and OpenStack. This connectivity typically requires accounts with appropriate permissions to act on behalf of the operator to access IaaS functionality such as creating virtual machines (VMs), managing networks and storage, and other related services.

Ops Manager and Pivotal Application Service (PAS) can be configured with IaaS users in different ways depending on your IaaS. Other product tiles and services might also use their own IaaS credentials. Refer to the documentation for those product tiles or services to configure them securely.

Least Privileged Users (LPUs)

Pivotal recommends following the principle of least privilege by scoping privileges to the most restrictive permissions possible for a given role. In the event that someone gains access to credentials by mistake or through malicious intent, LPUs limit the scope of the breach. Pivotal recommends following best practices for the particular IaaS you are deploying.

AWS Guidelines

See the recommendations detailed in the [AWS Permissions Guidelines](#) topic.

Azure Guidelines

See the permissions recommendations in [Preparing to Deploy Ops Manager on Azure Manually](#), and use the minimum permissions necessary when creating your service principal.

GCP Guidelines

For GCP, Pivotal recommends using two different accounts with the least privilege.

Use one account with the minimum permissions required to create desired GCP resources in your GCP project, then create a separate service account with the minimum permissions required to deploy PCF components such as Pivotal Ops Manager and PAS. For more information about creating the service account, see *Step 1: Set up IAM Service Accounts* in [Preparing to Deploy Ops Manager on GCP Manually](#).

OpenStack Guidelines

Pivotal recommends following the principle of least privilege by scoping privileges to the most restrictive permissions possible for a given role.

vSphere Guidelines

See the vCenter permissions recommendations in the [Installing Pivotal Cloud Foundry on vSphere](#) topic.

Installing PCF in Airgapped Environments

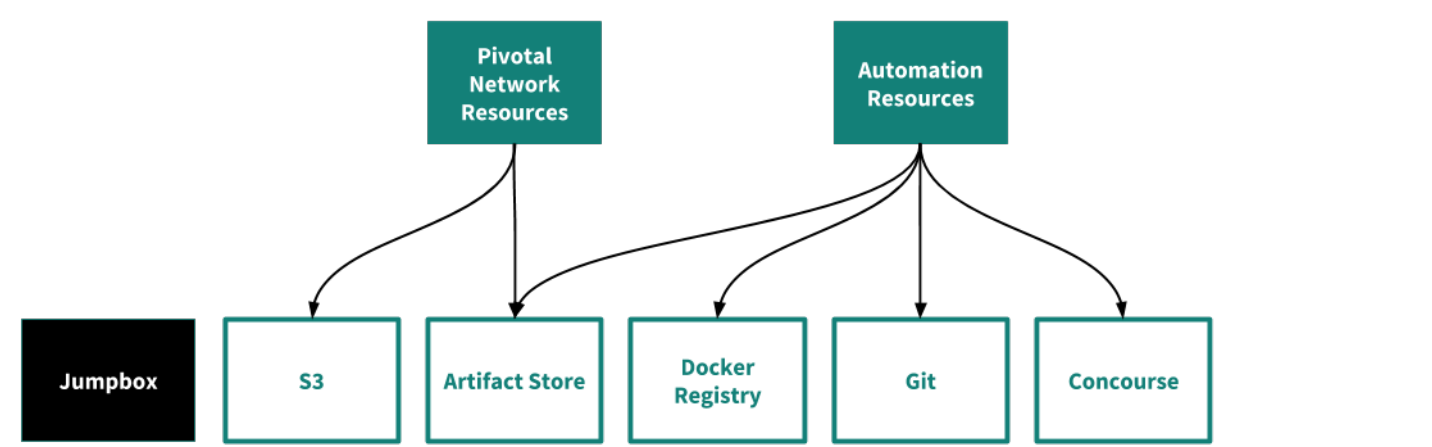

Page last updated:

This topic provides an overview of the components and resources needed to install PCF in airgapped environments, including the typical corresponding automation resources. It also describes one example solution that has been used in the past.

Offline Components

To run PCF offline, you must obtain resources from the internet and move them into offline components that store and use them. The method you use to move a resource from Pivotal Network or GitHub into an offline environment can vary from setting up a designated proxy to burning a DVD.

The following image displays types of resources and the components you must move them to in your offline environment. It also includes a jumpbox. The jumpbox is a Linux host for running commands such as `bosh`, `uaac`, and `fly`. You could use the Ops Manager VM for this purpose.

The following table provides more detail about resources and the component you must move them to:

| Resource | Component |
|---|--|
| Pivotal Network products such as tiles, stemcells, BOSH releases, and Ops Manager | S3 and artifact store |
| Pipelines and scripts | Git |
| Configuration | Git |
| Container images | Docker Registry, S3, or artifact store |
| Third Party Resources such as NSX-T and OSS BOSH releases | Artifact store |
| Backup artifacts | S3 |

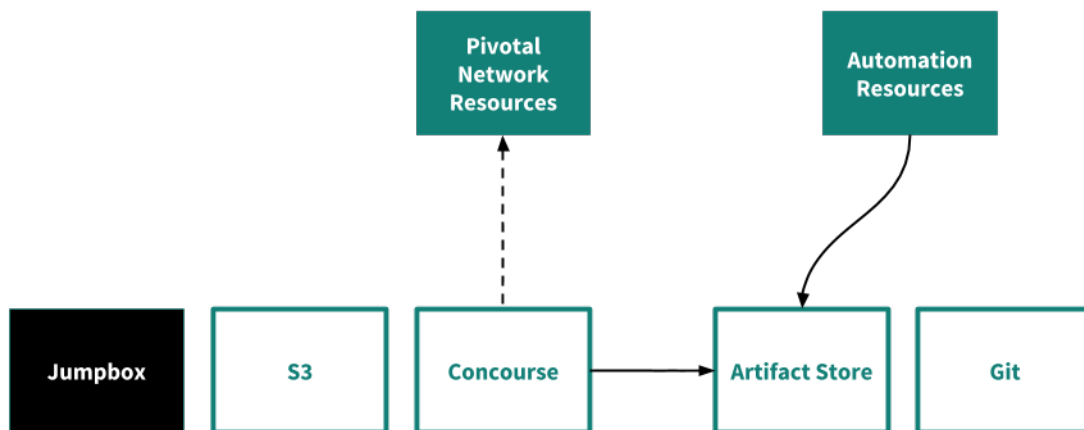

Architectural Patterns

The following sections describe three architectural patterns for running PCF in airgapped environments. The pattern you use depends on how your environment is set up.

Pattern One: Artifact Store with Internet Access

It is common for organizations to deploy an artifact store such as Artifactory or Nexus as a gateway to the Internet. In this configuration, the artifact store is typically configured as a Docker mirror.

This pattern includes an S3 component that is used only for backups of the PCF installation.

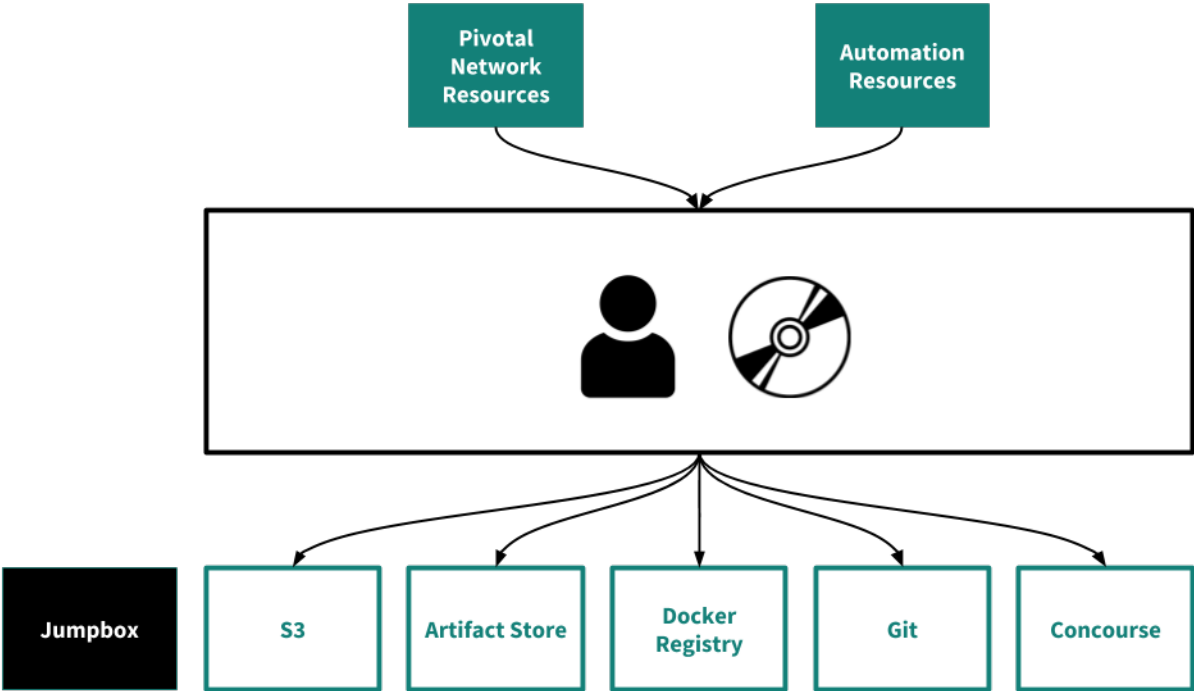

The following table provides an example of how you might handle resources in this scenario:

| Resource | Component |
|---|---|
| Pivotal Network products such as tiles, stemcells, BOSH releases, and Ops Manager | This architectural pattern presents the challenge of getting Pivotal Network resources from the Internet into the artifact store. For example, Artifactory and Nexus cannot interact directly with Pivotal Network. You could place Pivotal Network resources in an artifact store either through a remote Concourse worker with access to the Internet, by downloading them from the Internet and placing them in the artifact store manually, or some other method. |
| Pipelines and scripts | Store in Git. Use manual clone and push. Modify pipelines to use <code>registry_mirror</code> . |
| Configuration | Store in Git. Use manual clone and push. |
| Container images | Store in the artifact store that you configured as a mirror. |
| Third Party Resources such as NSX-T and OSS BOSH releases | Store in a generic artifact store repository. |
| Backup artifacts | Store in a S3 blobstore. |

Pattern Two: Completely Offline

In completely offline environments, you must bring in all resources manually and store them in the available local components.

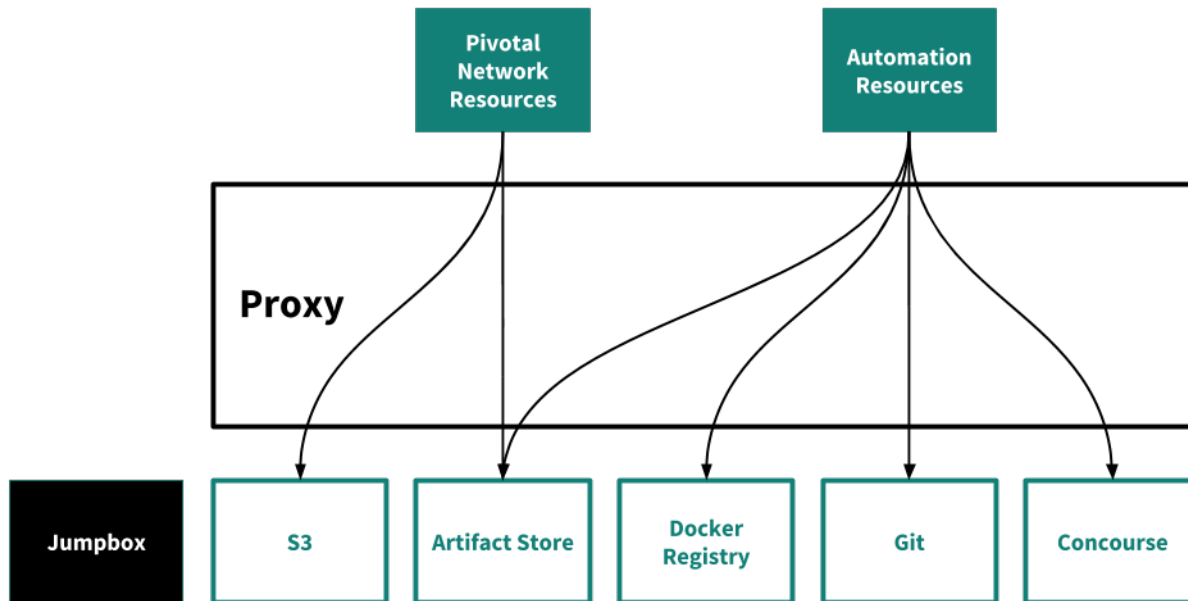

In this architectural pattern, you must configure pipelines to watch components for changes and apply updates when available. The following table provides an example of how you might handle resources in this scenario:

| Resource | Component |
|---|---|
| Pivotal Network products such as tiles, stemcells, BOSH releases, and Ops Manager | Manually upload to Nexus. |
| Pipelines and scripts | Modify pipelines to use a local Harbor Docker registry. Manually clone an online environment, bring it to the offline environment on DVD, and push it to offline Git. |
| Configuration | Store in your offline Git. |
| Container Images | Get from the Internet, transfer to USB, and push to offline Harbor. |
| Third Party Resources such as NSX-T and OSS BOSH releases | Store in a generic artifact store repository. |
| Backup artifacts | Store in a S3 blobstore. |

Pattern Three: TLS Intercepting Proxy

This pattern allows Internet access, but only through a proxy that decrypts and rewrites TLS certificates. In general, this resembles an online install, however it requires that you add your corporate certificate to all BOSH-deployed VMs.

Some of the challenges in this pattern include the following:

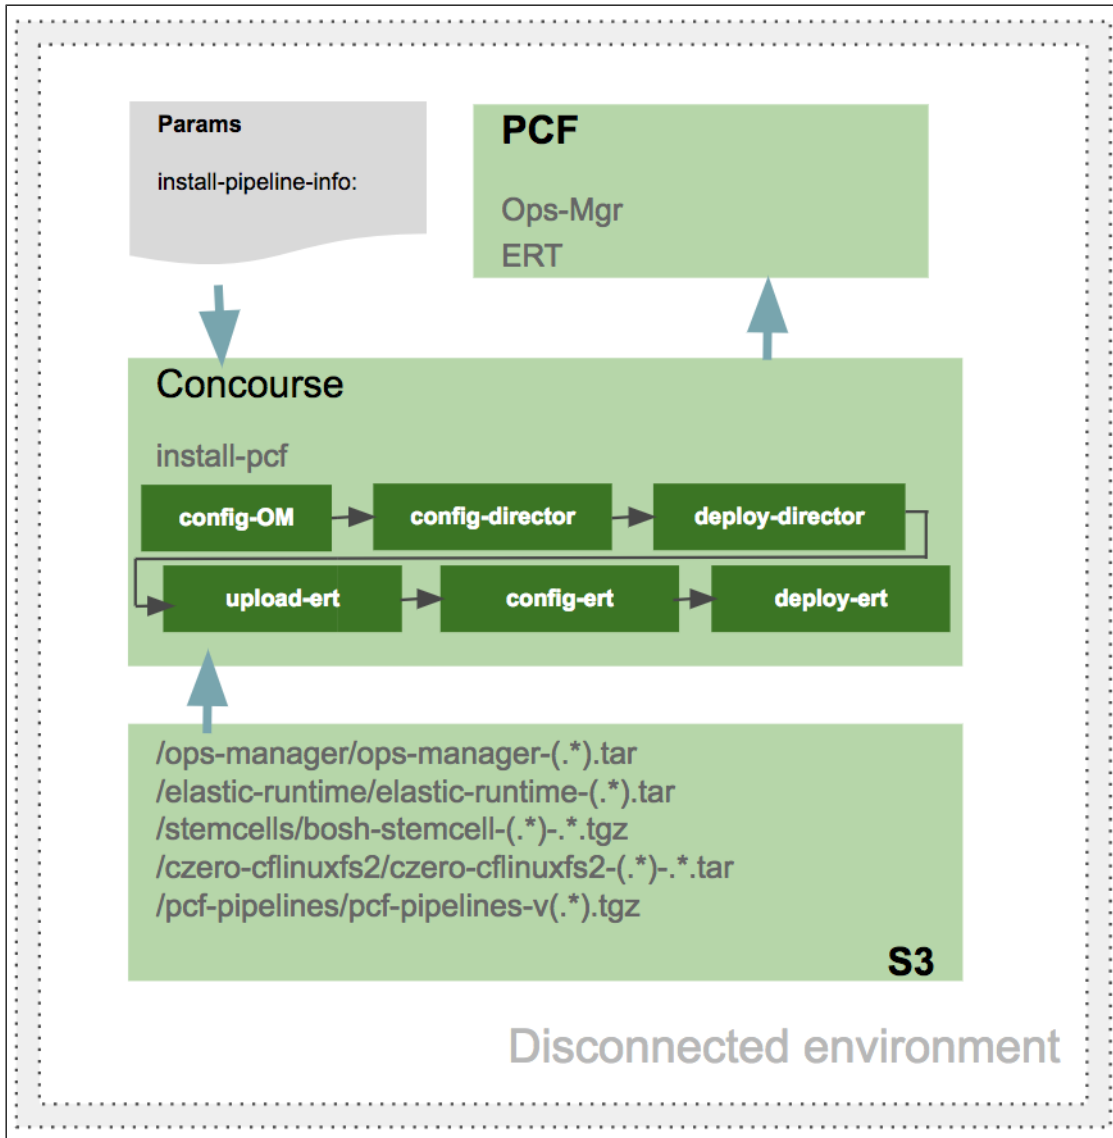

- Any automation that calls to the Internet will fail if it does not have the corporate certificate in its trust store.
- Concourse tasks that do not use resources do not receive updated BOSH root certificates. This means you must configure tasks to ignore TLS errors or update the root certificates as part of the tasks.

Example Installation in Airgapped Environment

In this example solution, an operator uses [Concourse](#) as the [control plane architecture](#) and specialized [PCF Pipelines](#) to deploy PCF to computer networks physically isolated from the Internet.

⚠ warning: At time of publication, the PCF Pipelines repository is undergoing planned deprecation. Use this document only as a model and reference when implementing your own solution.

The following diagram presents a high-level overview of this solution:

This implementation runs in two environments, one airgapped and one Internet-connected. Each environment has its own Concourse server and pipeline. The airgapped environment bootstraps from an internal S3 repository populated by contents moved over as `tar` files from the Internet-connected environment.

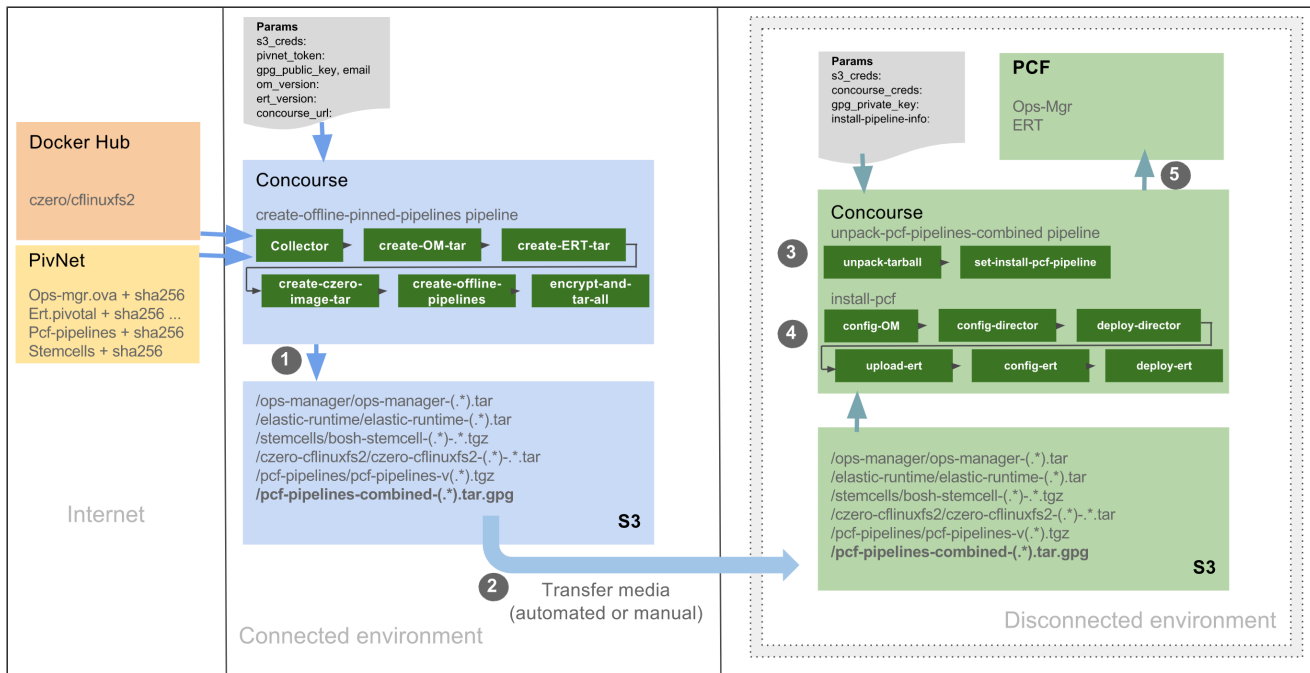

Requirements

This solution requires the following:

- Internet-connected environment with access to DockerHub and PivNet.
- Concourse v3.3.3 or later, installed in both the Internet-connected and airgapped environments.
- A path from the Internet-connected environment to the airgapped environment. All artifacts, such as release files, Docker images and scripts, must be downloaded and packaged within an Internet-connected network, then transferred to the airgapped environment.
- An offline S3-compatible blobstore. The airgapped Concourse pipeline retrieves artifacts from a Concourse [S3 Resource](#). There are many S3-compatible blobstores that you can use within airgapped environments, such as [Minio](#) and [Dell EMC Elastic Cloud Storage](#).

Bootstrap the Pipelines

As illustrated in the diagram below, two pipelines help bootstrap the offline environment, `create-offline-pinned-pipelines` and `unpack-pcf-pipelines-combined`. These pipelines are meant to facilitate physical transfer of artifacts to the airgapped environment.

Pipelines Execution Flow

1. Download artifacts from external sources, sign, package and upload them to S3 repository.
2. Move packaged artifacts to disconnected environment's S3 repository (either manual or automated.)
3. Unpack artifacts, check their signature and setup offline `pcf-pipelines` with new artifacts.
4. `pcf-pipelines` are triggered upon existence of new artifacts in S3 repository.
5. PCF is deployed by `pcf-pipelines` in disconnected environment.

Create Offline Pinned Pipelines

The `create-offline-pinned-pipelines` does the following:

- Pulls all required resources (images, products and pipelines) from their locations on the Internet and package them.
- Transforms `pcf-pipelines` to consume the resources from S3-compatible blobstore.
- Creates an encrypted tarball with all resources, and a shasum manifest for each resource.
- Puts the tarball to a location within S3 storage for it to be transferred to the airgapped environment.

To download this pipeline, see [create-offline-pinned-pipelines](#).

The following screenshot shows how this pipeline appears in the Concourse dashboard.

[View a larger version of this diagram.](#)

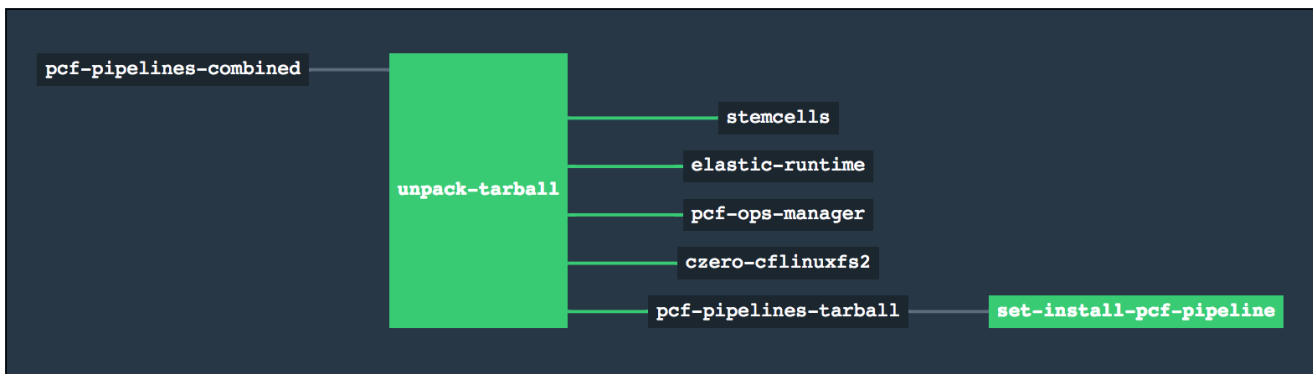

Unpack PCF Pipelines

The `unpack-pcf-pipelines-combined` does the following:

- Downloads, decrypts, and extracts the GPG-encrypted tarball into its components after it has been transferred to the `pcf-pipelines-combined/` path in the S3-compatible store.
- Verifies the `shasum` manifest of the tarball contents.
- Puts the tarball parts into their appropriate locations within the airgapped S3 storage for use by the pipelines.

To download this pipeline, see [unpack-pcf-pipelines-combined](#).

The following screenshot shows how this pipeline appears in the Concourse dashboard.

[View a larger version of this diagram.](#)

From this point, the `pcf-pipelines` folder in the configured S3 bucket in the airgapped environment contains the pcf-pipelines tarball that can then be used to set a pipeline on an airgapped Concourse, in the same fashion as a standard `pcf-pipelines` setup.

Bootstrapping Requirements

For the `unpack-pcf-pipelines-combined` to work, there must be a single manual transfer of the `cszero-cflinuxfs2` tarball to the `cszero-cflinuxfs2` folder within the airgapped environment's S3 storage. Only after that is done can the `unpack-pcf-pipelines-combined` pipeline be set and unpaused.

Install in the China Region

Question: I am a customer headquartered in the US with another location in China, but am experiencing problems downloading Pivotal software directly to my China location. What should I do?

Disclaimer: This question has legal implications, and Pivotal cannot provide legal advice to anyone about their specific obligations under any applicable laws and regulations in China or elsewhere (including, but not limited to, the laws and regulations on import/export and cyber security.) So you should seek legal guidance regarding your own import/export compliance under all the applicable laws or other obligations regarding this issue. The following

information is provided to you for your reference only. Pivotal expressly disclaims all liabilities in respect to actions taken or not taken based on the following information.

Certain customers have used the above solution under the above use case, which may or may not address your issue. A customer headquartered in the United States (U.S.) has another location in China, each with their own environments/systems. Customer downloads our software from Pivotal Network (PivNet) from our PivNet servers in the U.S. Customer employee then copies our software from the customer's environment in the U.S. to customer's environment in China. Customer's China location then uses that locally available version of our software, instead of downloading it directly from PivNet to customer's China location.

Installing Pivotal Cloud Foundry on AWS

Page last updated:

This guide describes how to install [Pivotal Cloud Foundry](#) (PCF) on Amazon Web Services (AWS).

Overview

You can install PCF on AWS with either the Pivotal Application Service (PAS) or Pivotal Container Service (PKS) runtime. There are resource requirements specific to each runtime. Ensure you meet the requirements for your runtime and the requirements specific to AWS before installing PCF on AWS.

Requirements

This section lists the following resource requirements for installing PCF on AWS:

- General PCF resource requirements. See [PCF Resource Requirements](#).
- AWS-specific resource requirements. See [AWS Resource Requirements](#).

PCF Resource Requirements

This section lists PCF resource requirements for installing PCF on AWS. It includes general PCF resource requirements for both the PAS and PKS runtimes.

View one of the following, depending on your PCF runtime:

- PAS-specific PCF resource requirements. See [PAS Resource Requirements](#).
- PKS-specific PCF resource requirements. See [PKS Resource Requirements](#).

PAS Resource Requirements

The following are general resource requirements for deploying and managing a PCF deployment with Ops Manager and PAS:

- PAS requires sufficient IP allocation. The following lists the minimum required IP allocations:
 - One static IP address for either HAProxy or one of your Gorouters
 - One static IP address for each job in the Ops Manager **Resource Config** pane for each tile for a full list.
 - One static IP address for each job listed below:
 - Consul
 - NATS
 - File Storage
 - MySQL Proxy
 - MySQL Server
 - Backup Restore Node
 - HAProxy
 - Router
 - MySQL Monitor
 - Diego Brain
 - TCP Router
 - One IP for each VM instance created by the service.
 - An additional IP address for each compilation worker. Use the following formula to determine the total IPs required:

$$\text{IPs needed} = \text{static IPs} + \text{VM instances} + \text{compilation workers}$$
 - Pivotal recommends that you allocate at least 36 dynamic IP addresses when deploying Ops Manager and PAS. BOSH requires additional dynamic IP addresses during installation to compile and deploy VMs, install PAS, and connect to services.
- Pivotal recommends using a network without DHCP for deploying PAS VMs.

Note: If you have DHCP, refer to the [Troubleshooting Guide](#) to avoid issues with your installation.

PKS Resource Requirements

For PKS-specific resource requirements, see [AWS Prerequisites and Resource Requirements](#).

AWS Resource Requirements

The following are AWS-specific resource requirements for installing PCF on AWS with an external database and external file storage:

- Installing PCF on AWS requires a minimum of the following VM instance limits in your AWS account. The number of VMs required depends on the number of tiles and availability zones you plan to deploy. The following VM guidelines apply to the PAS, Small Footprint PAS, and PKS runtimes:
 - PAS:** At a minimum, a new AWS deployment requires the following VMs for PAS:

| AWS Requirements | VM Name | VM Type | Default VM Count | Required or Optional VM |
|------------------|-------------------------------|-----------|------------------|-------------------------|
| PAS | Consul | t2.micro | 3 | Required |
| | NATS | t2.micro | 2 | Required |
| | File Storage | m4.large | 1 | Optional |
| | MySQL Proxy | t2.micro | 2 | Optional |
| | MySQL Server | r4.large | 3 | Optional |
| | Backup Restore Node | t2.micro | 1 | Optional |
| | Diego BBS | t2.micro | 3 | Required |
| | UAA | m4.large | 2 | Required |
| | Cloud Controller | m4.large | 2 | Required |
| | HAProxy | t2.micro | 1 | Optional |
| | Router | t2.micro | 3 | Required |
| | Service Discovery Controller | t2.micro | 2 | Optional |
| | MySQL Monitor | t2.micro | 1 | Optional |
| | Clock Global | t2.medium | 2 | Required |
| | Cloud Controller Worker | t2.micro | 2 | Required |
| | Diego Brain | t2.small | 3 | Required |
| | Diego Cell | r4.xlarge | 3 | Required |
| | Loggregator Trafficcontroller | t2.micro | 3 | Required |
| | Syslog Adapter | t2.micro | 3 | Required |
| | Syslog Scheduler | t2.micro | 2 | Required |
| | Doppler Server | m4.large | 3 | Required |
| | TCP Router | t2.micro | 0 | Optional |
| | CredHub | r4.large | 0 | Optional |
| Istio Router | r4.large | 0 | Optional | |
| Istio Control | r4.large | 0 | Optional | |
| Route Syncer | r4.large | 0 | Optional | |
| Ops Manager | BOSH Director | m4.large | 1 | Required |

Note: If you are deploying a test or sandbox PCF that does not require high availability, then you can scale down the number of VM instances in your deployment. For more information, see [Scaling PAS](#).

- Small Footprint PAS:** To run Small Footprint PAS, a new AWS deployment requires:

| AWS Requirements | VM Name | VM Type | Default VM Count | Minimum HA VM Count | Required or Optional VM |
|------------------|----------|-----------|------------------|---------------------|-------------------------|
| | Compute | r4.xlarge | 1 | 3 | Required |
| | Control | r4.xlarge | 1 | 2 | Required |
| | Database | r4.large | 1 | 3 | Required |
| | Router | t2.micro | 1 | 3 | Required |

| | | | | | |
|---------------------|---------------------|----------|---|----------|----------|
| Small Footprint PAS | File Storage | m4.large | 1 | N/A | Optional |
| | Backup Restore Node | t2.micro | 1 | 1 | Optional |
| | MySQL Monitor | t2.micro | 1 | 1 | Optional |
| | HAProxy | t2.micro | 0 | 2 | Optional |
| | TCP Router | t2.micro | 0 | 1 | Optional |
| Istio Router | r4.large | 0 | 1 | Optional | |
| Istio Control | r4.large | 0 | 2 | Optional | |
| Route Syncer | r4.large | 0 | 1 | Optional | |
| Ops Manager | BOSH Director | m4.large | 1 | N/A | Required |

- **PKS:** See [AWS Prerequisites and Resource Requirements](#).
- The following AWS resources are required for installing PCF on AWS with PAS:
 - 3 Elastic Load Balancers (ELBs)
 - 1 Relational Database Service. As a minimum, Pivotal recommends using a db.m3.xlarge instance with at least 100 GB of allocated storage.
 - 5 S3 Buckets

Prerequisites

To install PCF on AWS, you must do the following:

- Increase or remove the VM instance limits in your AWS account. Installing PCF requires more than the default 20 concurrent instances. For more information about VM resource requirements, see [Requirements](#).
- Configure your AWS account with the appropriate AWS region. For more information about selecting the correct region for your deployment, see [Region and Availability Zone Concepts](#) in the AWS documentation.
- Install the AWS CLI. Configure the AWS CLI with the user credentials that have admin access to your AWS account. To download the AWS CLI, see [AWS CLI](#).
- Configure an AWS EC2 key pair to use with your PCF deployment. For more information, see [Creating an EC2 Key Pair](#) in the AWS documentation.
- Register a wildcard domain for your PCF installation. For more information, see [SSL/TLS Certificates for Classic Load Balancers](#) in the AWS documentation.
- Create an SSL certificate for your PCF domain. For more information, see the [AWS documentation about SSL certificates](#).

 **Note:** To deploy PCF to a production environment, you must obtain a certificate from a certificate authority. Pivotal recommends using a self-signed certificate generated by Ops Manager for development and testing purposes only.

- **(PAS-only)** Configure sufficient IP allocation. For more information about IP allocation requirements, see [PAS Resource Requirements](#).
- **(Optional) (PAS-only)** Configure external storage. Pivotal recommends using external storage if possible. For more information about how file storage location affects platform performance and stability during upgrades, see [Configure File Storage](#).
- **(Optional) (PAS and Ops Manager-only)** Configure external databases. Pivotal recommends using external databases in production deployments for BOSH Director and PAS. An external database must be configured to use the UTC timezone.
- **(Optional) (PAS and Ops Manager-only)** Configure external user stores. When you deploy PCF, you can select a SAML user store for Ops Manager or a SAML or LDAP user store for PAS, to integrate existing user accounts.

Install PCF on AWS

You can install PCF on AWS either manually or using Terraform.

To install PCF on AWS, do one of the following:

- Install PCF on AWS manually. See [Installing PCF on AWS Manually](#).
- Install PCF on AWS using Terraform. See [Install PCF on AWS Using Terraform](#).

Additional Resources

The following are additional resources related to installing PCF on AWS:

- For information about AWS identity and access management, see [What is IAM?](#) in the AWS documentation.
- For information about users, groups, and roles in AWS, see [Identities \(Users, Groups, and Roles\)](#) in the AWS documentation.
- For best practices for managing IaaS users and permissions, see [Temporary Security Credentials](#) in the AWS documentation.
- For recommendations on how to create and scope AWS accounts for PCF, see [AWS Permissions Guidelines](#).
- For more information about certificate requirements for installing PCF, see [Certificate Requirements](#).

AWS Permissions Guidelines

Pivotal recommends that you minimize the use of master account credentials by creating an IAM role and instance profile with the minimum required EC2, VPC, and EBS credentials.

In addition, Pivotal recommends that you follow AWS account security best practices such as disabling root keys, using multi-factor authentication on the root account, and using CloudTrail for auditing API actions.

For more Amazon-specific best practices, refer to the following Amazon documentation:

- [IAM Roles Best Practices](#) 
- [AWS Security Best Practices Whitepaper](#) 
- [AWS Well-Architected Framework](#) 

Installing PCF on AWS Manually

Page last updated:

This topic describes how to manually configure the Amazon Web Services (AWS) components that you need to run [Pivotal Cloud Foundry](#) (PCF) on AWS.

To deploy PCF on AWS, you must perform the procedures in this topic to create objects in the AWS Management Console that PCF requires.

To view the list of AWS objects created by the procedures in this topic, see the [Required AWS Objects](#) section.

After completing the procedures in this topic, proceed to [Configuring BOSH Director on AWS](#) to continue deploying PCF.

Step 1: File a Ticket

Log in to the AWS Management Console, and file a ticket with Amazon to ensure that your account can launch more than the default 20 instances. In the ticket, ask for a limit of 50 `t2.micro` instances and 20 `c4.large` instances in the region you are using.

Note: To deploy PCF to AWS GovCloud (US), log in to the [AWS GovCloud \(US\) Console](#) instead of the standard AWS Management Console and select the `us-gov-west-1` region.

Note: To deploy PCF to AWS China, set up an [AWS China](#) account and contact the Platform Architect assigned for your Pivotal account.

You can check the limits on your account by visiting the EC2 Dashboard on the AWS Management Console and clicking **Limits** on the left navigation.

Step 2: Create S3 Buckets

1. Navigate to the S3 Dashboard.

Note: S3 bucket names must be globally unique. When naming buckets, Pivotal recommends that you prefix the generic names below with an unique and helpfully identifiable string (i.e. `ID-STRING-pcf-ops-manager-bucket`, `MY-IDENTIFIER-pcf-buildpacks-bucket`, and so on). Then you should use the same prefix when naming other associated resources, such as IAM policies.

2. Perform the following steps to create five S3 buckets:

- Click **Create Bucket**
- For **Bucket name**, enter `ID-STRING-pcf-ops-manager-bucket`.
- For **Region**, select your region.
- Click **Next** three times.
- Click **Create bucket**.
- Repeat the above steps to create four more S3 buckets: `ID-STRING-pcf-buildpacks-bucket`, `ID-STRING-pcf-packages-bucket`, `ID-STRING-pcf-resources-bucket`, and `ID-STRING-pcf-droplets-bucket`.

Step 3: Create an IAM User for PCF

Perform the following steps to create an Amazon Identity and Access Management (IAM) user with the minimal permissions necessary to run and install PCF:

1. Click **IAM** to access the IAM Dashboard.
2. Click **Users** and then click **Add user**.

Add user

1

2

3

4

Set user details

You can add multiple users at once with the same access type and permissions. [Learn more](#)

User name*

[+ Add another user](#)

Select AWS access type

Select how these users will access AWS. Access keys and autogenerated passwords are provided in the last step. [Learn more](#)

Access type* ☒ **Programmatic access**
Enables an **access key ID** and **secret access key** for the AWS API, CLI, SDK, and other development tools.

☐ **AWS Management Console access**
Enables a **password** that allows users to sign-in to the AWS Management Console.

* Required

[Cancel](#) [Next: Permissions](#)

3. Enter a user name, such as `pcf-user`.

4. For AWS access type, select **Programmatic access**.

 **Note:** If you prefer to create your keys locally and import them into AWS, see the [Amazon documentation](#).

5. Click **Next: Permissions**.

6. Click **Next: Review** and review your choices.

 **Note:** On the **Review** page you may see a warning that the user has no permissions. You can disregard this message. You do not need to set user permissions.

7. Click **Create user**.

8. Click **Download .csv** to download the user security credentials.

 **warning:** The `credentials.csv` contains the IDs for your user security access key and secret access key. Keep the `credentials.csv` file for your currently active key pairs in a secure directory. You cannot recover a lost key pair.

9. Click **Close**.

10. On the **Users** page, click the user name to access the user details page.

 **Note:** On the **Users** page you may see a warning that the user has no permissions. You can disregard this message. You do not need to set user permissions.

11. Click **Add inline policy**. You can review your existing inline policies by clicking the down arrow.

Create policy

A policy defines the AWS permissions that you can assign to a user, group, or role. You can create and edit a policy in the visual editor and using JSON. [Learn more](#)

This policy validation failed and might have errors converting to JSON : The policy must have at least one statement For more information about the IAM policy grammar, see [AWS IAM Policies](#)

Visual editor **JSON** [Import managed policy](#)

21      ],
22      "Resource": [
23        "*"
24      ]
25    }
26  ]
27 }
```

[Cancel](#) [Review policy](#)

12. On the **Create policy** page, define a policy:
 - a. Copy the policy document included in the [Pivotal Cloud Foundry for AWS Policy Document](#) topic. You must edit the policy document so the names of the S3 buckets match the ones you created in [Step 2: Create S3 Buckets](#).
 - b. Paste the policy document into the **JSON** tab on the **Create policy** page.
13. Click **Review policy**.
14. In the **Name** field, enter `pcf-iam-policy`.
15. Click **Create policy**. The **Summary** page displays a list of available policies and actions.

Step 4: Create a VPC

1. Navigate to the VPC Dashboard.
2. Click **Start VPC Wizard**.

VPC Dashboard

Filter by VPC: None

Virtual Private Cloud

Your VPCs

Subnets

Route Tables

Internet Gateways

DHCP Options Sets

Elastic IPs

Resources

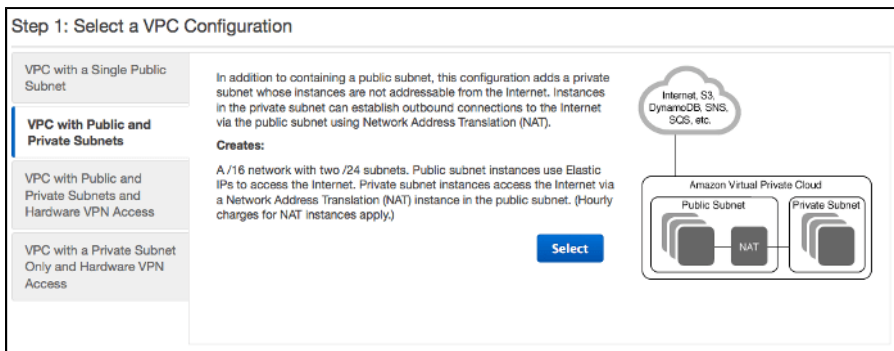

[Start VPC Wizard](#) [Launch EC2 Instances](#)

Note: Your Instances will launch in the US East (N. Virginia) region.

You are using the following Amazon VPC resources in the US East (N. Virginia) region:

| | |
|---------------------------|----------------------------|
| 2 VPCs | 2 Internet Gateways |
| 4 Subnets | 4 Route Tables |
| 2 Network ACLs | 3 Elastic IPs |
| 6 Security Groups | 18 Running Instances |
| 0 VPC Peering Connections | 0 Customer Gateways |
| 0 VPN Connections | 0 Virtual Private Gateways |

3. Select **VPC with Public and Private Subnets** and click **Select**.

4. Specify the following details for your VPC:

- **IPv4 CIDR block:** Enter `10.0.0.0/16`.
- **IPv6 CIDR block:** Select **No IPv6 CIDR Block**.
- **VPC name:** `pcf-vpc`.
- **Public subnet's IPv4 CIDR:** Enter `10.0.0.0/24`.
- Set the **Availability Zone** fields for both subnets to `REGION-#a`. For example, `us-west-2a`.
- **Public subnet name:** Enter `pcf-public-subnet-az0`.
- **Private subnet's IPv4 CIDR:** Enter `10.0.16.0/28`.
- **Private subnet name:** Enter `pcf-management-subnet-az0`.
- Click **Use a NAT instance instead** and do the following:
 - Under **Specify the details of your NAT instance**, set the **Instance type** to `t2.medium`
 - Create a key pair titled `pcf-ops-manager-key`. For more information on creating the key pair, see [Amazon EC2 Key Pairs](#) in the AWS documentation.
 - Select your newly-created `pcf-ops-manager-key` for the **Key Pair name**.
- **Enable DNS hostnames:** Click **Yes**.
- **Hardware tenancy:** Select **Default**.
- Click **Create VPC**.

5. After the VPC is successfully created, click **Subnets** in the left navigation.

6. Click **Create Subnet**.

7. Add the following subnets to the `pcf-vpc` VPC:

Note: You created the first two subnets in the previous step: `pcf-public-subnet-az0` and `pcf-management-subnet-az0`.

| Name | AZ | IPv4 CIDR block |
|--|--|----------------------------|
| <code>pcf-public-subnet-az1</code> | <code>REGION-#b</code> (for example, <code>us-west-2b</code>) | <code>10.0.1.0/24</code> |
| <code>pcf-public-subnet-az2</code> | <code>REGION-#c</code> (for example, <code>us-west-2c</code>) | <code>10.0.2.0/24</code> |
| <code>pcf-management-subnet-az1</code> | <code>REGION-#b</code> (for example, <code>us-west-2b</code>) | <code>10.0.16.16/28</code> |
| <code>pcf-management-subnet-az2</code> | <code>REGION-#c</code> (for example, <code>us-west-2c</code>) | <code>10.0.16.32/28</code> |
| <code>pcf-ert-subnet-az0</code> | <code>REGION-#a</code> (for example, <code>us-west-2a</code>) | <code>10.0.4.0/24</code> |
| <code>pcf-ert-subnet-az1</code> | <code>REGION-#b</code> (for example, <code>us-west-2b</code>) | <code>10.0.5.0/24</code> |
| <code>pcf-ert-subnet-az2</code> | <code>REGION-#c</code> (for example, <code>us-west-2c</code>) | <code>10.0.6.0/24</code> |
| <code>pcf-services-subnet-az0</code> | <code>REGION-#a</code> (for example, <code>us-west-2a</code>) | <code>10.0.8.0/24</code> |
| <code>pcf-services-subnet-az1</code> | <code>REGION-#b</code> (for example, <code>us-west-2b</code>) | <code>10.0.9.0/24</code> |
| <code>pcf-services-subnet-az2</code> | <code>REGION-#c</code> (for example, <code>us-west-2c</code>) | <code>10.0.10.0/24</code> |
| <code>pcf-rds-subnet-az0</code> | <code>REGION-#a</code> (for example, <code>us-west-2a</code>) | <code>10.0.12.0/24</code> |
| <code>pcf-rds-subnet-az1</code> | <code>REGION-#b</code> (for example, <code>us-west-2b</code>) | <code>10.0.13.0/24</code> |
| <code>pcf-rds-subnet-az2</code> | <code>REGION-#c</code> (for example, <code>us-west-2c</code>) | <code>10.0.14.0/24</code> |

Step 5: Configure a Security Group for Ops Manager

1. Return to the EC2 Dashboard.
2. Select **Security Groups>Create Security Group**.
3. For **Security group name**, enter `pcf-ops-manager-security-group`.
4. For **Description**, enter a description to identify this security group.
5. For **VPC**, select the VPC where you want to deploy Ops Manager.
6. Click the **Inbound** tab and add rules according to the table below.

Note: Pivotal recommends limiting access to Ops Manager to IP ranges within your organization, but you may relax the IP restrictions after configuring authentication for Ops Manager.

| Type | Protocol | Port Range | Source |
|---------------|----------|------------|-------------|
| HTTP | TCP | 80 | My IP |
| HTTPS | TCP | 443 | My IP |
| SSH | TCP | 22 | My IP |
| BOSH Agent | TCP | 6868 | 10.0.0.0/16 |
| BOSH Director | TCP | 25555 | 10.0.0.0/16 |

7. Click **Create**.

Step 6: Configure a Security Group for PCF VMs

1. From the **Security Groups** page, click **Create Security Group** to create another security group.
2. For **Security group name**, enter `pcf-vms-security-group`.
3. For **Description**, enter a description to identify this security group.
4. For **VPC**, select the VPC where you want to deploy the PCF VMs.
5. Click the **Inbound** tab and add rules for all traffic from your public and private subnets to your private subnet, as the table and image show. This rule configuration does the following:
 - Enables BOSH to deploy PAS and other services.
 - Enables application VMs to communicate through the router.
 - Allows the load balancer to send traffic to Pivotal Application Service (PAS).

| Type | Protocol | Port Range | Source |
|-------------|----------|------------|-----------------------|
| All traffic | All | 0 - 65535 | Custom IP 10.0.0.0/16 |

6. Click **Create**.

The screenshot shows the AWS Management Console interface for creating a security group. The 'Security group name' is 'pcf/vms', the 'Description' is 'pcf/vms', and the 'VPC' is 'vpc-1e4b1a7b (10.0.0.0/16) pcf-vpc'. Under 'Security group rules', the 'Inbound' tab is active, showing a table with one rule: 'All traffic' from 'Custom IP 10.0.0.0/16' on ports '0 - 65535'.

Step 7: Configure a Security Group for the Web ELB

1. From the **Security Groups** page, click **Create Security Group** to create another security group.

- For **Security group name**, enter `pcf-web-elb-security-group`.
- For **Description**, enter a description to identify this security group.
- For **VPC**, select the VPC where you want to deploy this Elastic Load Balancer (ELB).
- Click the **Inbound** tab and add rules to allow traffic to ports `80`, `443`, and `4443` from `0.0.0.0/0`, as the table and image show.

Note: Allow traffic to port `4443` only if you are in an AWS cloud region that does not support AWS ALBs. For example, the GovCloud region. For more information about AWS regions and availability zones, see [AWS Global Infrastructure](#).

Note: For finer control over what can reach PAS, change `0.0.0.0/0` to be more restrictive. This security group governs external access to PAS from apps such as the cf CLI and app URLs.

| Type | Protocol | Port Range | Source | |
|-----------------|----------|------------|----------|-----------|
| Custom TCP rule | TCP | 4443 | Anywhere | 0.0.0.0/0 |
| HTTP | TCP | 80 | Anywhere | 0.0.0.0/0 |
| HTTPS | TCP | 443 | Anywhere | 0.0.0.0/0 |

- Click **Create**.

Create Security Group

Security group name i

Description i

VPC i

Security group rules:

Inbound

Outbound

| Type <small>i</small> | Protocol <small>i</small> | Port Range <small>i</small> | Source <small>i</small> | Description <small>i</small> |
|-----------------------------|---------------------------|-----------------------------|---|------------------------------|
| Custom TCP <small>i</small> | TCP | 4443 | Anywhere <small>i</small> 0.0.0.0/0, ::/0 | e.g. SSH for Admin Desktop |
| HTTP <small>i</small> | TCP | 80 | Anywhere <small>i</small> 0.0.0.0/0, ::/0 | e.g. SSH for Admin Desktop |
| HTTPS <small>i</small> | TCP | 443 | Anywhere <small>i</small> 0.0.0.0/0, ::/0 | e.g. SSH for Admin Desktop |

Add Rule

Cancel

Create

Step 8: Configure a Security Group for the SSH ELB

- From the **Security Groups** page, click **Create Security Group** to create another security group.
- For **Security group name**, enter `pcf-ssh-elb-security-group`.
- For **Description**, enter a description to identify this security group.
- For **VPC**, select the VPC where you want to deploy this ELB.
- Click the **Inbound** tab and add the following rule:

| Type | Protocol | Port Range | Source | |
|-----------------|----------|------------|----------|-----------|
| Custom TCP rule | TCP | 2222 | Anywhere | 0.0.0.0/0 |

- Click **Create**.

Step 9: Configure a Security Group for the TCP ELB

1. From the **Security Groups** page, click **Create Security Group** to create another security group.
2. For **Security group name**, enter `pcf-tcp-elb-security-group`.
3. For **Description**, enter a description to identify this security group.
4. For **VPC**, select the VPC where you want to deploy this ELB.
5. Click the **Inbound** tab and add the following rule:

| Type | Protocol | Port Range | Source | |
|-----------------|----------|-------------|----------|-----------|
| Custom TCP rule | TCP | 1024 - 1123 | Anywhere | 0.0.0.0/0 |

6. Click **Create**.

Step 10: Configure a Security Group for the Outbound NAT

1. From the **Security Groups** page, click **Create Security Group** to create another security group.
2. For **Security group name**, enter `pcf-nat-security-group`.
3. For **Description**, enter a description to identify this security group.
4. For **VPC**, select the VPC where you want to deploy the Outbound NAT.
5. Click the **Inbound** tab and add a rule to allow all traffic from your VPCs, as the table and image show.

| Type | Protocol | Port Range | Source | |
|-------------|----------|------------|-----------|-------------|
| All traffic | All | All | Custom IP | 10.0.0.0/16 |

6. Click **Create**.

The screenshot shows the AWS Security Groups console. The 'Security group name' is 'OutboundNAT' and the 'Description' is 'OutboundNAT'. The 'VPC' is 'vpc-8ec593eb (10.0.0.0/16) | pcf-vpc'. Under 'Security group rules', the 'Inbound' tab is selected. A rule is added with 'Type' as 'All traffic', 'Protocol' as 'All', 'Port Range' as '0 - 65535', and 'Source' as 'Custom IP' with the value '10.0.0.0/16'.

Step 11: Configure a Security Group for MySQL

Note: If you plan to use an internal database, skip this step. If you are using RDS, you must configure a security group that enables the Ops Manager VM and BOSH Director VM to access the database.

1. From the **Security Groups** page, click **Create Security Group** to create another security group.
2. For **Security group name**, enter `pcf-mysql-security-group`.
3. For **Description**, enter a description to identify this security group.
4. For **VPC**, select the VPC where you want to deploy MySQL.
5. Click the **Inbound** tab. Add a rule of type `MySQL` and specify the subnet of your VPC in **Source**, as the table and image show.

| Type | Protocol | Port Range | Source | |
|-------|----------|------------|-----------|-------------|
| MySQL | TCP | 3306 | Custom IP | 10.0.0.0/16 |

- Click the **Outbound** tab. Add a rule of type **All traffic** and specify the subnet of your VPC in **Destination**, as the table and image show.

| Type | Protocol | Port Range | Destination | |
|-------------|----------|------------|-------------|-------------|
| All traffic | All | All | Custom IP | 10.0.0.0/16 |

- Click **Create**.

Step 12: Launch an Ops Manager AMI

To launch an Amazon Machine Image (AMI) for Ops Manager, do the following:

- Navigate to the **Pivotal Cloud Foundry Operations Manager** section of [Pivotal Network](#).
- Select the version of PCF you want to install from the **Releases** dropdown.
- In the **Release Download Files**, click the file named **Pivotal Cloud Foundry Ops Manager for AWS** to download a PDF.
- Open the PDF and identify the AMI ID for your region.
- Return to the EC2 Dashboard.
- Click **AMIs** from the **Images** menu.
- Select **Public images** from the drop-down filter that says **Owned by me**.
- Paste the AMI ID for your region into the search bar and press enter.

Note: There is a different AMI for each region. If you cannot locate the AMI for your region, verify that you have set your AWS Management Console to your desired region. If you still cannot locate the AMI, log in to the [Pivotal Network](#) and file a support ticket.

- (Optional) If you want to encrypt the VM that runs Ops Manager with AWS Key Management Service (KMS), perform the following additional steps:
 - Right click the row that lists your AMI and click **Copy AMI**.
 - Select your **Destination region**.
 - Enable **Encryption**. For more information about AMI encryption, see [Encryption and AMI Copy](#) from the *Copying an AMI* topic in the AWS documentation.
 - Select your **Master Key**. To create a new custom key, see [Creating Keys](#) in the AWS documentation.
 - Click **Copy AMI**. You can use the new AMI you copied for the following steps.
- Select the row that lists your Ops Manager AMI and click **Launch**.
- Choose **m3.large** for your instance type and click **Next: Configure Instance Details**.

| | Family | Type | vCPUs | Memory (GiB) | Instance Storage (GiB) |
|----------------------------------|-----------------|--------------------------------|-------|--------------|------------------------|
| <input type="checkbox"/> | Micro instances | t1.micro Free tier eligible | 1 | 0.613 | EBS only |
| <input checked="" type="radio"/> | General purpose | t2.micro Free tier eligible | 1 | 1 | EBS only |
| <input checked="" type="radio"/> | General purpose | t2.small | 1 | 2 | EBS only |
| <input checked="" type="radio"/> | General purpose | t2.medium | 2 | 4 | EBS only |
| <input type="checkbox"/> | General purpose | m3.medium | 1 | 3.75 | 1 x 4 (SSD) |
| <input checked="" type="radio"/> | General purpose | m3.large | 2 | 7.5 | 1 x 32 (SSD) |

12. Configure the following for your instance:

- **Network:** Select the VPC that you created.
- **Subnet:** Select `pcf-public-subnet-az0`.
- **Auto-assign for Public IP:** Select **Enable**.
- **IAM role:** Select the IAM role associated with your pcf-user profile. If you have not created one, click **Create new IAM role** and follow the [Guidelines for Creating User Roles on AWS](#).
- For all other fields, accept the default values.

1. Choose AMI
2. Choose Instance Type
3. Configure Instance
4. Add Storage
5. Tag Instance
6. Configure Security Group
7. Review

Step 3: Configure Instance Details

Configure the instance to suit your requirements. You can launch multiple instances from the same AMI, request Spot Instances to take advantage of the lower pricing, assign an access management role to the instance, and more.

Number of instances ⓘ

Purchasing option ⓘ ☐ Request Spot Instances

Network ⓘ ⓘ Create new VPC

Subnet ⓘ ⓘ Create new subnet
250 IP Addresses available

Auto-assign Public IP ⓘ

IAM role ⓘ ⓘ Create new IAM role

Shutdown behavior ⓘ

Enable termination protection ⓘ ☐ Protect against accidental termination

Monitoring ⓘ ☐ Enable CloudWatch detailed monitoring
Additional charges apply.

Tenancy ⓘ ⓘ Additional charges will apply for dedicated tenancy.

13. Click **Next: Add Storage** and adjust the **Size (GiB)** value. The default persistent disk value is 50 GB. Pivotal recommends increasing this value to a minimum of 100 GB.

1. Choose AMI
2. Choose Instance Type
3. Configure Instance
4. Add Storage
5. Tag Instance
6. Configure Security Group
7. Review

Step 4: Add Storage

Your instance will be launched with the following storage device settings. You can attach additional EBS volumes and instance store volumes to your instance, or edit the settings of the root volume. You can also attach additional EBS volumes after launching an instance, but not instance store volumes. [Learn more](#) about storage options in Amazon EC2.

| Type | Device | Snapshot | Size (GiB) | Volume Type | IOPS | Delete on Termination | Encrypted |
|------------------|-----------|---------------|----------------------------------|-----------------------|------------|-------------------------------------|---------------|
| Root | /dev/sda1 | snap-f1ce6d7e | <input type="text" value="100"/> | General Purpose (SSD) | 150 / 3000 | <input checked="" type="checkbox"/> | Not Encrypted |
| Instance Store 0 | /dev/sdb | N/A | N/A | N/A | N/A | N/A | Not Encrypted |

14. Click **Next: Tag Instance**

15. On the **Add Tags** page, add a tag with the key `Name` and value `pcf-ops-manager`.

16. Click **Next: Configure Security Group**.

17. Select the `pcf-ops-manager-security-group` that you created in [Step 5: Configure a Security Group for Ops Manager](#).

18. Click **Review and Launch** and confirm the instance launch details.

19. Click **Launch**.
20. Select the `pcf-ops-manager-key` key pair, confirm that you have access to the private key file, and click **Launch Instances**. You use this key pair to access the Ops Manager VM.

Select an existing key pair or create a new key pair ✕

A key pair consists of a **public key** that AWS stores, and a **private key file** that you store. Together, they allow you to connect to your instance securely. For Windows AMIs, the private key file is required to obtain the password used to log into your instance. For Linux AMIs, the private key file allows you to securely SSH into your instance.

Note: The selected key pair will be added to the set of keys authorized for this instance. Learn more about [removing existing key pairs from a public AMI](#).

Choose an existing key pair

Select a key pair

pcf

☒ I acknowledge that I have access to the selected private key file (pcf.pem), and that without this file, I won't be able to log into my instance.

Cancel Launch Instances

21. Click **View Instances** to access the **Instances** page on the EC2 Dashboard.

Step 13: Create Web Load Balancer

1. On the EC2 Dashboard, click **Load Balancers**.
2. Click **Create Load Balancer**.
3. Under **Application Load Balancer**, click **Create**.
4. For **Step 1: Configure Load Balancer**, do the following:
 - a. Under **Basic Configuration**, do the following:
 - For **Name**, enter `pcf-web-elb`.
 - For **Scheme**, select **internet-facing** to allow traffic from public IP addresses, or **internal** to allow traffic only from private IP addresses.
 - For **IP address type**, select the type of IP addresses you want to allow.
 - b. Under **Listeners**, click **Add listener**. For **Load Balancer Protocol**, select **HTTPS**.
 - c. Under **Availability Zones**, select all availability zones.
 - d. Click **Next: Configure Security Settings**.
5. For **Step 2: Configure Security Settings**, do the following:
 - a. Under **Select default certificate**, do one of the following:
 - If you already have a certificate from AWS Certificate Manager (ACM), select **Choose a certificate from ACM**.
 - If you do not have a certificate from ACM, select **Upload a certificate to ACM**. For more information, see [Importing Certificates into AWS Certificate Manager](#) in the AWS documentation.

Note: For a production or production-like environment, use a certificate from a Certificate Authority (CA). This can be an internal certificate or a purchased certificate. For a sandbox environment, you can use a self-signed certificate.

 - b. For **Certificate Name**, select the desired certificate.
 - c. For **Security Policy**, select the policy you created in [Step 3: Create an IAM User for PCF](#).
 - d. Click **Next: Configure Security Groups**.
6. For **Step 3: Configure Security Groups**, do the following:
 - a. Under **Assign a security group**, select **Select an existing security group**.
 - b. From the list of security groups, select the `pcf-web-elb-security-group` security group that you configured in [Step 7: Configure a Security Group for the Web ELB](#).
 - c. Click **Next: Configure Routing**.

7. For **Step 4: Configure Routing**, do the following:

a. Under **Target Group**, enter the following values:

- **Name:** Enter `pcf-web-elb-target-group`.
- **Protocol:** Select **HTTP**.

b. Under **Health checks**, set **Path** to `/health`.

c. Under **Advanced health check settings**, enter the following values:

- **Port:** Set to `8080`.
- **Interval:** Set to `5` seconds.
- **Timeout:** Set to `3` seconds.
- **Unhealthy threshold:** Set to `3`.
- **Health threshold:** Set to `6`.

d. Click **Next: Register Targets**.

8. For **Step 5: Register Targets**, accept the default values and click **Next: Review**.

9. For **Step 6: Review**, review the load balancer details and then click **Create**. A message appears to confirm AWS successfully created the load balancer.

Step 14: Create SSH Load Balancer

1. From the **Load Balancers** page, click **Create Load Balancer**.

2. Select **Classic Load Balancer**.

3. Configure the load balancer with the following information:

- **Load Balancer name:** Enter `pcf-ssh-elb`.
- **Create LB Inside:** Select the `pcf-vpc` VPC that you created in [Step 4: Create a VPC](#).
- Ensure that the **Create an internal load balancer** checkbox is not selected.

1. Define Load Balancer
2. Assign Security Groups
3. Configure Security Settings
4. Configure Health Check
5. Add EC2 Instances
6. Add Tags
7. Review

Step 1: Define Load Balancer

Basic Configuration

This wizard will walk you through setting up a new load balancer. Begin by giving your new load balancer a unique name so that you can identify it from other load balancers you might create. You will also need to configure ports and protocols for your load balancer. Traffic from your clients can be routed from any load balancer port to any port on your EC2 instances. By default, we've configured your load balancer with a standard web server on port 80.

Load Balancer name:

Create LB Inside:

Create an internal load balancer: ☐ [\(what's this?\)](#)

Enable advanced VPC configuration: ☒

Listener Configuration:

| Load Balancer Protocol | Load Balancer Port | Instance Protocol | Instance Port |
|------------------------|--------------------|-------------------|---------------|
| HTTP | 80 | HTTP | 80 |

[Add](#)

Select Subnets

You will need to select a Subnet for each Availability Zone where you wish traffic to be routed by your load balancer. If you have instances in only one Availability Zone, please select at least two Subnets in different Availability Zones to provide higher availability for your load balancer.

VPC `vpc-e2210d87 (10.0.0.0/16) | pcf-vpc`

Please select at least two Subnets in different Availability Zones to provide higher availability for your load balancer.

Available Subnets

| Actions | Availability Zone | Subnet ID | Subnet CIDR | Name |
|---------|-------------------|-----------------|-------------|----------------|
| | us-east-1c | subnet-ac5fc2f5 | 10.0.1.0/24 | Private subnet |

Selected Subnets

| Actions | Availability Zone | Subnet ID | Subnet CIDR | Name |
|---------|-------------------|-----------------|-------------|---------------|
| | us-east-1c | subnet-af5fc2f6 | 10.0.0.0/24 | Public subnet |

- Under **Listener Configuration**, add the following rules:

| Load Balancer Protocol | Load Balancer Port | Instance Protocol | Instance Port |
|------------------------|--------------------|-------------------|---------------|
| TCP | 2222 | TCP | 2222 |

- Under **Select Subnets**, select the public subnets you configured in [Step 4: Create a VPC](#), and click **Next: Assign Security Groups**.
- On the **Assign Security Groups** page, select the security group `pcf-ssh-elb-security-group` you configured in [Step 8: Configure a Security Group for the SSH ELB](#), and click **Next: Configure Security Settings**.

1. Define Load Balancer
2. Assign Security Groups
3. Configure Security Settings
4. Configure Health Check
5. Add EC2 Instances
6. Add Tags
7. Review

Step 2: Assign Security Groups

You have selected the option of having your Elastic Load Balancer inside of a VPC, which allows you to assign security groups to your load balancer. Please select the security groups to assign to this load balancer. This can be changed at any time.

Assign a security group: ☐ Create a **new** security group
☒ Select an **existing** security group

Filter `VPC security groups`

| Security Group ID | Name | Description | Actions |
|---|-----------------------|----------------------------|-----------------------------|
| <input type="checkbox"/> sg-41693b25 | default | default VPC security group | Copy to new |
| <input type="checkbox"/> sg-f6c29092 | MySQL | MySQL | Copy to new |
| <input type="checkbox"/> sg-10dd8f74 | OpsManager | OpsManager | Copy to new |
| <input type="checkbox"/> sg-3ec2905a | OutboundNAT | OutboundNAT | Copy to new |
| <input type="checkbox"/> sg-88dd8fec | PCF VMs | PCF VMs | Copy to new |
| <input checked="" type="checkbox"/> sg-48c2902c | PCF_ELB_SecurityGroup | PCF_ELB_SecurityGroup | Copy to new |

- On the **Configure Security Settings** page, ignore the **Improve your load balancer's security** error message and click **Next: Configure Health Check**.
- On the **Configure Health Check** page, enter the following values:
 - Ping Protocol:** Select `TCP`.
 - Ping Port:** Set to `2222`.
 - Interval:** Set to `5` seconds.
 - Response Timeout:** Set to `3` seconds.
 - Unhealthy threshold:** Set to `3`.
 - Health threshold:** Set to `6`.

- Click **Next: Add EC2 Instances**.

1. Define Load Balancer
2. Assign Security Groups
3. Configure Security Settings
4. Configure Health Check
5. Add EC2 Instances
6. Add Tags
7. Review

Step 4: Configure Health Check

Your load balancer will automatically perform health checks on your EC2 instances and only route traffic to instances that pass the health check. If an instance fails the health check, it is automatically removed from the load balancer. Customize the health check to meet your specific needs.

Ping Protocol `TCP`

Ping Port `80`

Advanced Details

| | | |
|--------------------------------|-----------------|---------|
| Response Timeout ⓘ | <code>5</code> | seconds |
| Health Check Interval ⓘ | <code>10</code> | seconds |
| Unhealthy Threshold ⓘ | <code>2</code> | |
| Healthy Threshold ⓘ | <code>10</code> | |

- Accept the defaults on the **Add EC2 Instances** page and click **Next: Add Tags**.
- Accept the defaults on the **Add Tags** page and click **Review and Create**.
- Review and confirm the load balancer details, and click **Create**.

Step 15: Create TCP Load Balancer

1. From the **Load Balancers** page, click **Create Load Balancer**.
2. Select **Classic Load Balancer**.
3. Configure the load balancer with the following information:
 - **Load Balancer name:** Enter `pcf-tcp-elb`.
 - **Create LB Inside:** Select the `pcf-vpc` VPC that you created in [Step 4: Create a VPC](#).
 - Ensure that the **Create an internal load balancer** checkbox is not selected.

1. Define Load Balancer
2. Assign Security Groups
3. Configure Security Settings
4. Configure Health Check
5. Add EC2 Instances
6. Add Tags
7. Review

Step 1: Define Load Balancer

Basic Configuration

This wizard will walk you through setting up a new load balancer. Begin by giving your new load balancer a unique name so that you can identify it from other load balancers you might create. You will also need to configure ports and protocols for your load balancer. Traffic from your clients can be routed from any load balancer port to any port on your EC2 instances. By default, we've configured your load balancer with a standard web server on port 80.

Load Balancer name:

Create LB Inside:

Create an internal load balancer: ☐ (what's this?)

Enable advanced VPC configuration: ☒

Listener Configuration:

| Load Balancer Protocol | Load Balancer Port | Instance Protocol | Instance Port |
|------------------------|--------------------|-------------------|---------------|
| HTTP | 80 | HTTP | 80 |

Add

Select Subnets

You will need to select a Subnet for each Availability Zone where you wish traffic to be routed by your load balancer. If you have instances in only one Availability Zone, please select at least two Subnets in different Availability Zones to provide higher availability for your load balancer.

VPC vpc-e2210d87 (10.0.0.0/16) | pcf-vpc

Please select at least two Subnets in different Availability Zones to provide higher availability for your load balancer.

Available Subnets

| Actions | Availability Zone | Subnet ID | Subnet CIDR | Name |
|---------|-------------------|-----------------|-------------|----------------|
| + | us-east-1c | subnet-ac5fc2f5 | 10.0.1.0/24 | Private subnet |

Selected Subnets

| Actions | Availability Zone | Subnet ID | Subnet CIDR | Name |
|---------|-------------------|-----------------|-------------|---------------|
| - | us-east-1c | subnet-af5fc2f6 | 10.0.0.0/24 | Public subnet |

4. Under **Listener Configuration**, add the following rules:

| Load Balancer Protocol | Load Balancer Port | Instance Protocol | Instance Port |
|------------------------|--------------------|-------------------|---------------|
| TCP | 1024 | TCP | 1024 |
| TCP | 1025 | TCP | 1025 |
| TCP | 1026 | TCP | 1026 |
| ... | ... | ... | ... |
| TCP | 1123 | TCP | 1123 |

The `...` entry above indicates that you must add listening rules for each port between 1026 and 1123.

5. Under **Select Subnets**, select the public subnets you configured in [Step 4: Create a VPC](#), and click **Next: Assign Security Groups**.
6. On the **Assign Security Groups** page, select the security group `pcf-tcp-elb-security-group` you configured in [Step 9: Configure a Security Group for the TCP ELB](#), and click **Next: Configure Security Settings**.

1. Define Load Balancer 2. Assign Security Groups 3. Configure Security Settings 4. Configure Health Check 5. Add EC2 Instances 6. Add Tags 7. Review

Step 2: Assign Security Groups

You have selected the option of having your Elastic Load Balancer inside of a VPC, which allows you to assign security groups to your load balancer. Please select the security groups to assign to this load balancer. This can be changed at any time.

Assign a security group: ☐ Create a new security group ☒ Select an existing security group

Filter **VPC security groups**

| Security Group ID | Name | Description | Actions |
|---|-----------------------|----------------------------|-----------------------------|
| <input type="checkbox"/> sg-41693b25 | default | default VPC security group | Copy to new |
| <input type="checkbox"/> sg-f6c29092 | MySQL | MySQL | Copy to new |
| <input type="checkbox"/> sg-10dd8f74 | OpsManager | OpsManager | Copy to new |
| <input type="checkbox"/> sg-3ec2905a | OutboundNAT | OutboundNAT | Copy to new |
| <input type="checkbox"/> sg-88dd8fec | PCF VMs | PCF VMs | Copy to new |
| <input checked="" type="checkbox"/> sg-48c2902c | PCF_ELB_SecurityGroup | PCF_ELB_SecurityGroup | Copy to new |

7. On the **Configure Security Settings** page, ignore the **Improve your load balancer's security** error message and click **Next: Configure Health Check**.

8. On the **Configure Health Check** page, enter the following values:

- o **Ping Protocol:** Select **TCP**.
- o **Ping Port:** Set to **80**.
- o **Interval:** Set to **5** seconds.
- o **Response Timeout:** Set to **3** seconds.
- o **Unhealthy threshold:** Set to **3**.
- o **Health threshold:** Set to **6**.

9. Click **Next: Add EC2 Instances**.

1. Define Load Balancer 2. Assign Security Groups 3. Configure Security Settings 4. Configure Health Check 5. Add EC2 Instances 6. Add Tags 7. Review

Step 4: Configure Health Check

Your load balancer will automatically perform health checks on your EC2 instances and only route traffic to instances that pass the health check. If an instance fails the health check, it is automatically removed from the load balancer. Customize the health check to meet your specific needs.

Ping Protocol **TCP**

Ping Port **80**

Advanced Details

Response Timeout **5** seconds

Health Check Interval **10** seconds

Unhealthy Threshold **2**

Healthy Threshold **10**

10. Accept the defaults on the **Add EC2 Instances** page and click **Next: Add Tags**.

11. Accept the defaults on the **Add Tags** page and click **Review and Create**.

12. Review and confirm the load balancer details, and click **Create**.

Step 16: Configure DNS Records

- Perform the following steps for all three of the load balancers you created in previous steps, named **pcf-web-elb**, **pcf-ssh-elb**, and **pcf-tcp-elb**:
 - From the **Load Balancers** page, select the load balancer.
 - On the **Description** tab, locate the **Basic Configuration** section and record the **DNS name** of the load balancer.
- Click **Instances** on the left navigation to view your EC2 instances.
- Select the **PcfOpsManInstance** instance created by Cloudformation.
- On the **Description** tab, record the value for **IPv4 Public IP**.

5. Navigate to your DNS provider and create the following CNAME and A records:

- o CNAME: `*.apps.YOUR-SYSTEM-DOMAIN.com` and `*.system.YOUR-SYSTEM-DOMAIN.com` points to the DNS name of the `pcf-web-elb` load balancer.
- o CNAME: `ssh.YOUR-SYSTEM-DOMAIN.com` points to the DNS name of the `pcf-ssh-elb` load balancer.
- o CNAME: `tcp.YOUR-SYSTEM-DOMAIN.com` points to the DNS name of the `pcf-tcp-elb` load balancer.
- o A: `pcf.YOUR-SYSTEM-DOMAIN.com` points to the public IP address of the `pcf-ops-manager` EC2 instance.

Step 17: Secure the NAT Instance

1. On the EC2 Dashboard, click **Instances**.
2. Select the NAT instance, which has an instance type of `t2.medium`.
3. From the **Actions** menu, select **Networking>Change Security Groups**.
4. Change the NAT security group from the default group to the `pcf-nat-security-group` NAT security group that you created in [Step 10: Configure a](#)

Change Security Groups

Instance ID: i-be6cbb69
Interface ID: eni-9e3bdfb2

Select Security Group(s) to associate with your instance

| Security Group ID | Name | Description |
|---|-----------------------|----------------------------|
| <input type="checkbox"/> sg-04bdda60 | default | default VPC security group |
| <input type="checkbox"/> sg-6d85e209 | ElasticRuntime | ElasticRuntime |
| <input type="checkbox"/> sg-7e80e71a | MySQL | MySQL |
| <input type="checkbox"/> sg-37b8df53 | OpsManager | OpsManager |
| <input checked="" type="checkbox"/> sg-1482e570 | OutboundNAT | OutboundNAT |
| <input type="checkbox"/> sg-0283e466 | PCF_ELB_SecurityGroup | PCF_ELB_SecurityGroup |

[Security Group for the Outbound NAT.](#)

[Cancel](#) [Assign Security Groups](#)

5. Click **Assign Security Groups**.

Step 18: Create RDS Subnet Group

1. Navigate to the RDS Dashboard.
2. Perform the following steps to create a RDS Subnet Group for the two RDS subnets:
 - a. Click **Subnet Groups>Create DB Subnet Group**.
 - b. Enter the following values:
 - **Name:** Enter `pcf-rds-subnet-group`.
 - **Description:** Enter a description to identify this subnet group.
 - **VPC ID:** Select `pcf-vpc`.
 - **Availability Zone and Subnet ID:** Choose the AZ and subnet for `pcf-rds-subnet-az0` and click **Add**.
 - c. Repeat the steps above to add `pcf-rds-subnet-az1` and `pcf-rds-subnet-az2` to the group.
 - d. Click **Create**.

The following screenshot shows a completed subnet group.

Create DB Subnet Group

To create a new Subnet Group give it a name, description, and select an existing VPC below. Once you select an existing VPC, you will be able to add subnets related to that VPC.

Name ⓘ

Description ⓘ

VPC ID ⓘ

Add Subnet(s) to this Subnet Group. You may add subnets one at a time below or [add all the subnets](#) related to this VPC. You may make additions/edits after this group is created. A minimum of 2 subnets is required.

Availability Zone ⓘ

Subnet ID ⓘ

| Availability Zone | Subnet ID | CIDR Block | Action |
|-------------------|-----------------|-------------|---------------------------------------|
| us-east-1b | subnet-970765e0 | 10.0.3.0/24 | <input type="button" value="Remove"/> |
| us-east-1a | subnet-119c343a | 10.0.2.0/24 | <input type="button" value="Remove"/> |

 **Note:** On the Subnet Group page, you may need to refresh the page to view the new group.

Step 19: Create a MySQL Database Using AWS RDS

 **Note:** You must have an empty MySQL database when you install or reinstall PCF on AWS.

1. Navigate to the RDS Dashboard.
2. Click **Instances>Launch DB Instance** to launch the wizard.
3. Select **MySQL**.
4. Select the **MySQL** radio button under **Production** to create a database for production environments.
5. Click **Next Step**.
6. Specify the following database details:
 - **DB Instance Class:** Select **db.m3.large - 2 vCPU, 7.5 GiB RAM**.
 - **Multi-AZ Deployment:** Select **Yes**.
 - **Storage Type:** Select **Provisioned IOPS (SSD)**.
 - **Allocated Storage:** Enter **100 GB**.
 - **DB Instance Identifier:** Enter **pcf-ops-manager-director**.
 - Enter a secure **Master Username** and **Master Password**.

 **Note:** Record the username and password. You need these credentials later when configuring the **Director Config** page in the BOSH Director tile.

Launch DB Instance

Select to encrypt the given instance. Master key ids and aliases appear in the list after they have been created using the Key Management Service(KMS) console. [Learn More](#).

- Click **Launch DB Instance**. Launching the instance may take several minutes.
- When the instance has launched, proceed to [Configuring BOSH Director on AWS](#) to continue deploying PCF.

Required AWS Objects

This section describes the AWS objects you create in the procedures above in order to deploy PCF.

Use this section to determine the resource requirements of PCF on AWS, or to verify that you created the correct resources after completing the procedures above.

S3 Buckets for Ops Manager and PAS

You must create the following S3 buckets from the S3 Dashboard:

- `pcf-ops-manager-bucket`
- `pcf-buildpacks-bucket`
- `pcf-packages-bucket`
- `pcf-resources-bucket`
- `pcf-droplets-bucket`

These buckets must be empty when you install or reinstall PCF.

See [Step 2: Create S3 Buckets](#).

IAM User for PCF

You must create an IAM user for PCF named `pcf-user` from the Identity and Access Management Dashboard, using the policy document included in the [Pivotal Cloud Foundry for AWS Policy Document](#) [topic](#).

See [Step 3: Create an IAM User for PCF](#).

Key Pair

You must generate a key pair named `pcf-ops-manager-key`. For more information about setting up a key pair, see [Amazon EC2 Key Pairs](#) [in the AWS documentation](#).

VPC (Public and Private Subnets)

You must create a VPC with public and private subnets from the VPC Dashboard.

The following table lists the subnets in CIDR block `10.0.0.0/16`.

| Name | AZ | IPv4 CIDR block |
|--|---|----------------------------|
| <code>pcf-public-subnet-az0</code> | REGION-#a (for example, <code>us-west-2a</code>) | <code>10.0.0.0/24</code> |
| <code>pcf-public-subnet-az1</code> | REGION-#b (for example, <code>us-west-2b</code>) | <code>10.0.1.0/24</code> |
| <code>pcf-public-subnet-az2</code> | REGION-#c (for example, <code>us-west-2c</code>) | <code>10.0.2.0/24</code> |
| <code>pcf-management-subnet-az0</code> | REGION-#a (for example, <code>us-west-2a</code>) | <code>10.0.16.0/28</code> |
| <code>pcf-management-subnet-az1</code> | REGION-#b (for example, <code>us-west-2b</code>) | <code>10.0.16.16/28</code> |
| <code>pcf-management-subnet-az2</code> | REGION-#c (for example, <code>us-west-2c</code>) | <code>10.0.16.32/28</code> |
| <code>pcf-ert-subnet-az0</code> | REGION-#a (for example, <code>us-west-2a</code>) | <code>10.0.4.0/24</code> |
| <code>pcf-ert-subnet-az1</code> | REGION-#b (for example, <code>us-west-2b</code>) | <code>10.0.5.0/24</code> |
| <code>pcf-ert-subnet-az2</code> | REGION-#c (for example, <code>us-west-2c</code>) | <code>10.0.6.0/24</code> |
| <code>pcf-services-subnet-az0</code> | REGION-#a (for example, <code>us-west-2a</code>) | <code>10.0.8.0/24</code> |
| <code>pcf-services-subnet-az1</code> | REGION-#b (for example, <code>us-west-2b</code>) | <code>10.0.9.0/24</code> |
| <code>pcf-services-subnet-az2</code> | REGION-#c (for example, <code>us-west-2c</code>) | <code>10.0.10.0/24</code> |
| <code>pcf-rds-subnet-az0</code> | REGION-#a (for example, <code>us-west-2a</code>) | <code>10.0.12.0/24</code> |
| <code>pcf-rds-subnet-az1</code> | REGION-#b (for example, <code>us-west-2b</code>) | <code>10.0.13.0/24</code> |
| <code>pcf-rds-subnet-az2</code> | REGION-#c (for example, <code>us-west-2c</code>) | <code>10.0.14.0/24</code> |

See [Step 4: Create a VPC](#).

NAT Instance

You must create a NAT instance when creating a VPC. The NAT instance must have the following configuration:

- **Instance type:** `t2.medium`
- **Key pair name:** `pcf-ops-manager-key`
- **Enable DNS hostnames:** Yes
- **Hardware tenancy:** Default

See [Step 4: Create a VPC](#).

You must also assign the NAT instance to the `pcf-nat-security-group`. See [Step 17: Secure the NAT Instance](#).

Security Groups

The following sections describe the security groups you must create from the EC2 Dashboard.

Ops Manager

The Ops Manager Security Group must be named `pcf-ops-manager-security-group` and have the following inbound rules:

| Type | Protocol | Port Range | Source |
|---------------|----------|------------|-------------|
| HTTP | TCP | 80 | My IP |
| HTTPS | TCP | 443 | My IP |
| SSH | TCP | 22 | My IP |
| BOSH Agent | TCP | 6868 | 10.0.0.0/16 |
| BOSH Director | TCP | 25555 | 10.0.0.0/16 |

See [Step 5: Configure a Security Group for Ops Manager](#).

PCF VMs

The PCV VMs Security Group must be named `pcf-vms-security-group` and have the following inbound rule:

| Type | Protocol | Port Range | Source |
|-------------|----------|------------|--------------------------|
| All traffic | All | 0 - 65535 | Custom IP 10.0.0.0/16 |

See [Step 6: Configure a Security Group for PCF VMs](#).

Web ELB

The Web ELB Security Group must be named `pcf-web-elb-security-group` and have the following inbound rules:

| Type | Protocol | Port Range | Source |
|-----------------|----------|------------|-----------------------|
| Custom TCP rule | TCP | 4443 | Anywhere 0.0.0.0/0 |
| HTTP | TCP | 80 | Anywhere 0.0.0.0/0 |
| HTTPS | TCP | 443 | Anywhere 0.0.0.0/0 |

See [Step 7: Configure a Security Group for the Web ELB](#).

SSH ELB

The SSH ELB Security Group must be named `pcf-ssh-elb-security-group` and have the following inbound rule:

| Type | Protocol | Port Range | Source |
|------|----------|------------|--------|
| | | | |

| | | | | |
|-----------------|-----|------|----------|-----------|
| Custom TCP rule | TCP | 2222 | Anywhere | 0.0.0.0/0 |
|-----------------|-----|------|----------|-----------|

The SSH ELB Security Group must have the following outbound rule:

| Type | Protocol | Port Range | Source | |
|-------------|----------|------------|----------|-----------|
| All traffic | All | All | Anywhere | 0.0.0.0/0 |

See [Step 8: Configure a Security Group for the SSH ELB](#).

TCP ELB

The TCP ELB Security Group must be named `pcf-tcp-elb-security-group` and have the following inbound rule:

| Type | Protocol | Port Range | Source | |
|-----------------|----------|-------------|----------|-----------|
| Custom TCP rule | TCP | 1024 - 1123 | Anywhere | 0.0.0.0/0 |

The TCP ELB Security Group must have the following outbound rule:

| Type | Protocol | Port Range | Source | |
|-------------|----------|------------|----------|-----------|
| All traffic | All | All | Anywhere | 0.0.0.0/0 |

See [Step 9: Configure a Security Group for the TCP ELB](#).

Outbound NAT

The Outbound NAT Security Group must be named `pcf-nat-security-group` and have the following inbound rule:

| Type | Protocol | Port Range | Source | |
|-------------|----------|------------|-----------|-------------|
| All traffic | All | All | Custom IP | 10.0.0.0/16 |

See [Step 10: Configure a Security Group for the Outbound NAT](#).

MySQL

The MySQL Security Group must be named `pcf-mysql-security-group` and have the following inbound rules:

| Type | Protocol | Port Range | Source | |
|-------|----------|------------|-----------|-------------|
| MySQL | TCP | 3306 | Custom IP | 10.0.0.0/16 |

The MySQL Security Group must have the following outbound rules:

| Type | Protocol | Port Range | Destination | |
|-------------|----------|------------|-------------|-------------|
| All traffic | All | All | Custom IP | 10.0.0.0/16 |

See [Step 11: Configure a Security Group for MySQL](#).

Ops Manager AMI

You must locate the public Ops Manager AMI using the AMI ID provided by the PDF downloaded when clicking **Pivotal Cloud Foundry Ops Manager for AWS** on Pivotal Network.

See [Step 12: Launch a Pivotal Ops Manager AMI](#).

ELBs

The following sections describe the ELBs you must create from the EC2 Dashboard.

Web ELB

You must create a web ELB with the following configuration:

- **Name:** `pcf-web-elb`
- **LB Inside:** `pcf-vpc`
- **Selected Subnet:** `pcf-public-subnet-az0`, `pcf-public-subnet-az1`, `pcf-public-subnet-az2`
- **Security Group:** `pcf-elb-security-group`
- **Health Check:** TCP Port 8080, Path: `/health`

See [Step 13: Create Web Load Balancer](#).

SSH ELB

- **Name:** `pcf-ssh-elb`
- **LB Inside:** `pcf-vpc`
- **Selected Subnet:** `pcf-public-subnet-az0`, `pcf-public-subnet-az1`, `pcf-public-subnet-az2`
- **Security Group:** `pcf-ssh-security-group`
- **Health Check:** TCP Port 2222

See [Step 14: Create SSH Load Balancer](#).

TCP ELB

- **Name:** `pcf-tcp-elb`
- **LB Inside:** `pcf-vpc`
- **Selected Subnet:** `pcf-public-subnet-az0`, `pcf-public-subnet-az1`, `pcf-public-subnet-az2`
- **Security Group:** `pcf-tcp-security-group`
- **Health Check:** TCP Port 80

See [Step 15: Create TCP Load Balancer](#).

DNS Configuration

You must navigate to your DNS provider and create CNAME and A records for all three of your load balancers.

See [Step 16: Configure DNS Records](#).

RDS Subnet Group

You must create a subnet group for RDS named `pcf-rds-subnet-group` from the RDS Dashboard.

See [Step 18: Create RDS Subnet Group](#).

MySQL Database

You must create a MySQL database from the RDS Dashboard.

See [Step 19: Create a MySQL Database using AWS RDS](#).

Configuring BOSH Director on AWS

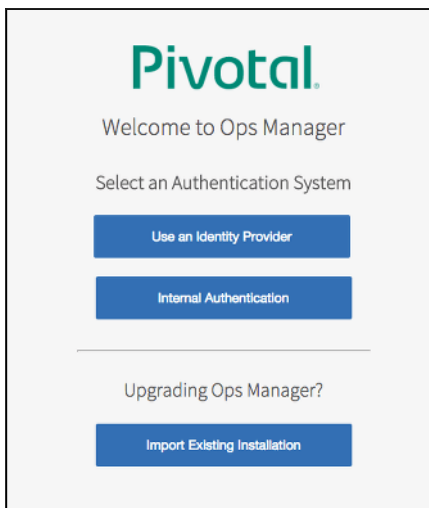

Page last updated:

This topic describes how to configure Ops Manager to deploy Pivotal Cloud Foundry (PCF) on Amazon Web Services (AWS).

Before beginning this procedure, ensure that you have successfully completed all of the steps in the [Installing PCF on AWS Manually](#) topic.

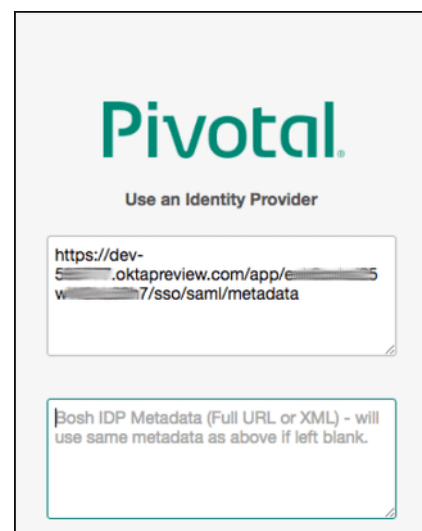

Step 1: Access Ops Manager

1. In a web browser, navigate to the fully qualified domain you created in the [Configure DNS Records](#) step of *Installing PCF on AWS Manually*.
2. When Ops Manager starts for the first time, you must choose one of the following:
 - [Use an Identity Provider](#): If you use an Identity Provider, an external identity server maintains your user database.
 - [Internal Authentication](#): If you use Internal Authentication, Ops Manager maintains your user database.

Use an Identity Provider (IdP)

1. Log in to your IdP console and download the IdP metadata XML. Optionally, if your IdP supports metadata URL, you can copy the metadata URL instead of the XML.

2. Copy the IdP metadata XML or URL to the Ops Manager **Use an Identity Provider** login page.

Note: The same IdP metadata URL or XML is applied for the BOSH Director. If you use a separate IdP for BOSH, copy the metadata XML or

URL from that IdP and enter it into the BOSH IdP Metadata text box in the Ops Manager login page.

3. Enter values for the fields listed below. Failure to provide values in these fields results in a 500 error.

 **Note:** These attributes are case-sensitive.

- **SAML admin group:** Enter the name of the SAML group that contains all Ops Manager administrators.
- **SAML groups attribute:** Enter the groups attribute tag name with which you configured the SAML server.

4. Enter your **Decryption passphrase**. Read the **End User License Agreement**, and select the checkbox to accept the terms.

5. Your Ops Manager login page appears. Enter your username and password. Click **Login**.

6. Download your SAML Service Provider metadata (SAML Relying Party metadata) by navigating to the following URLs:

- **6a.** Ops Manager SAML service provider metadata: `https://OPS-MAN-FQDN:443/uaa/saml/metadata`
- **6b.** BOSH Director SAML service provider metadata: `https://BOSH-IP-ADDRESS:8443/saml/metadata`

 **Note:** To retrieve your `BOSH-IP-ADDRESS`, navigate to the **BOSH Director** tile > **Status** tab. Record the **BOSH Director** IP address.

7. Configure your IdP with your SAML Service Provider metadata. Import the Ops Manager SAML provider metadata from Step 6a above to your IdP. If your IdP does not support importing, provide the values below.

- **Single sign on URL:** `https://OPS-MAN-FQDN:443/uaa/saml/SSO/alias/OPS-MAN-FQDN`
- **Audience URI (SP Entity ID):** `https://OP-MAN-FQDN:443/uaa`
- **Name ID:** Email Address
- SAML authentication requests are always signed

8. Import the BOSH Director SAML provider metadata from Step 6b to your IdP. If the IdP does not support an import, provide the values below.

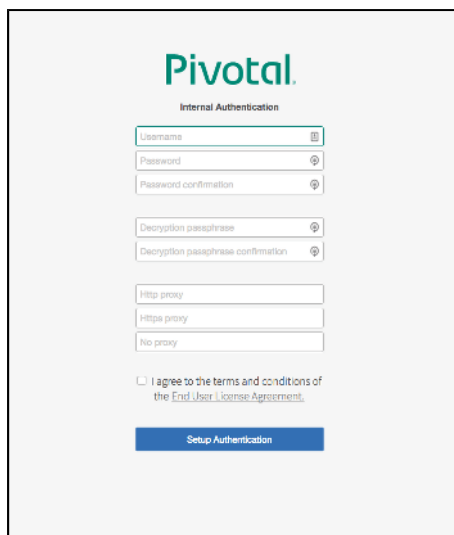

- **Single sign on URL:** `https://BOSH-IP:8443/saml/SSO/alias/BOSH-IP`
- **Audience URI (SP Entity ID):** `https://BOSH-IP:8443`
- **Name ID:** Email Address
- SAML authentication requests are always signed

9. Return to the **BOSH Director** tile, and continue with the configuration steps below.

Internal Authentication

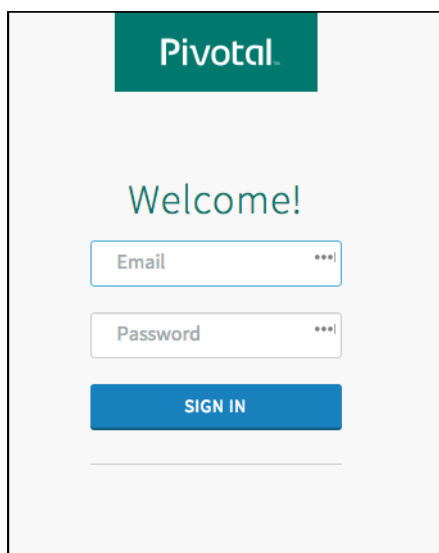

1. When redirected to the **Internal Authentication** page, do the following:

- Enter a **Username**, **Password**, and **Password confirmation** to create an Admin user.
- Enter a **Decryption passphrase** and the **Decryption passphrase confirmation**. This passphrase encrypts the Ops Manager datastore, and is not recoverable.
- If you are using an **HTTP proxy** or **HTTPS proxy**, follow the instructions in the [Configuring Proxy Settings for the BOSH CPI](#) topic.
- Read the **End User License Agreement**, and select the checkbox to accept the terms.
- Click **Setup Authentication**.

The image shows the 'Internal Authentication' setup page in Pivotal. It features the Pivotal logo at the top. Below the logo, the text 'Internal Authentication' is displayed. The form includes several input fields: 'Username', 'Password', 'Password confirmation', 'Decryption passphrase', and 'Decryption passphrase confirmation'. Each of these fields has a small icon to its right. Below these fields are three radio button options for 'Http proxy', 'Https proxy', and 'No proxy'. At the bottom of the form, there is a checkbox labeled 'I agree to the terms and conditions of the End User License Agreement.' and a blue button labeled 'Setup Authentication'.

2. Log in to Ops Manager with the Admin username and password you created in the previous step.

The image shows the 'Welcome!' login page in Pivotal. It features the Pivotal logo at the top. Below the logo, the text 'Welcome!' is displayed. The form includes two input fields: 'Email' and 'Password'. Each field has a small icon to its right. Below these fields is a blue button labeled 'SIGN IN'.

Step 2: AWS Config Page

1. Click the **BOSH Director** tile.

2. Select **AWS Config**.

3. Select **Use AWS Keys** or **Use AWS Instance Profile**.

- **Access Key ID** and **AWS Secret Key**: To retrieve your AWS key information, use the AWS Identity and Access Management (IAM) credentials that you generated in the [Step 3: Create an IAM User for PCF](#) section of the *Installing PCF on AWS Manually* topic.
- **AWS IAM Instance Profile**: Enter the name of the IAM profile you created in the [Step 3: Create an IAM User for PCF](#) section of the *Installing PCF on AWS Manually* topic.

4. Complete the rest of the **AWS Management Console Config** page:

- **Security Group ID**: Enter the **Group ID** of the `pcf-vms-security-group` you created for your PCF VMs in the [Step 6: Configure a Security Group for PCF VMs](#) section of the *Installing PCF on AWS Manually* topic. Locate the Group ID in the **Security Groups** tab of your EC2 Dashboard.
- **Key Pair Name**: Enter `pcf-ops-manager-key`.
- **SSH Private Key**: Open the AWS key pair `pcf-ops-manager-keys.pem` file you generated in the [Step 3: Create an IAM User for PCF](#) section of the *Installing PCF on AWS Manually* topic. Copy the contents of the `.pem` file and paste it into the **SSH Private Key** field.
- **Region**: Select the region where you deployed Ops Manager.
- **Encrypt EBS Volumes**: Select this checkbox to enable full encryption on persistent disks of all BOSH-deployed VMs except the Ops Manager VM and Director VM. See the [Configuring Amazon EBS Encryption for PCF on AWS](#) topic for details about using EBS encryption.

Note: Enabling EBS encryption only encrypts Linux VMs. The Windows VMs deployed with Pivotal Application Service (PAS) for Windows or PAS for Windows 2012R2 are not encrypted.

5. Click **Save**.

Step 3: Director Config Page

1. Select **Director Config**.

Director Config

NTP Servers (comma delimited) *

JMX Provider IP Address

Bosh HM Forwarder IP Address

☐ Enable VM Resurrector Plugin

☐ Enable Post Deploy Scripts

☐ Recreate all VMs

This will force BOSH to recreate all VMs on the next deploy. Persistent disk will be preserved

☐ Enable bosh deploy retries

This will attempt to re-deploy a failed deployment up to 5 times.

☐ Keep Unreachable Director VMs

2. Enter at least two of the following NTP servers in the **NTP Servers (comma delimited)** field, separated by a comma:

0.amazon.pool.ntp.org, 1.amazon.pool.ntp.org, 2.amazon.pool.ntp.org, 3.amazon.pool.ntp.org

Note: The NTP server configuration only updates after VM recreation. Ensure that you select the **Recreate all VMs** checkbox if you modify the value of this field.

3. Leave the **JMX Provider IP Address** field blank.

Note: Starting from PCF v2.0, BOSH-reported component metrics are available in the Loggregator Firehose by default. Therefore, if you continue to use PCF JMX Bridge for consuming them outside of the Firehose, you may receive duplicate data. To prevent this, leave the **JMX Provider IP Address** field blank. For additional guidance, see [BOSH System Metrics Available in Loggregator Firehose](#).

4. Leave the **Bosh HM Forwarder IP Address** field blank.

Note: Starting from PCF v2.0, BOSH-reported component metrics are available in the Loggregator Firehose by default. Therefore, if you continue to use the BOSH HM Forwarder for consuming them, you may receive duplicate data. To prevent this, leave the **Bosh HM Forwarder IP Address** field blank. For additional guidance, see [BOSH System Metrics Available in Loggregator Firehose](#).

5. Select the **Enable VM Resurrector Plugin** checkbox to enable the Ops Manager Resurrector functionality and increase Pivotal Application Service (PAS) availability. For more information, see the [Using Ops Manager Resurrector on VMware vSphere](#) topic.
6. Select **Enable Post Deploy Scripts** to run a post-deploy script after deployment. This script allows the job to execute additional commands against a deployment.

Note: You must enable post-deploy scripts to install PKS.

7. Select **Recreate all VMs** to force BOSH to recreate all VMs on the next deploy. This process does not destroy any persistent disk data.
8. Select **Enable bosh deploy retries** if you want Ops Manager to retry failed BOSH operations up to five times.
9. (Optional) Disable **Allow Legacy Agents** if all of your tiles have stemcells v3468 or later. Disabling the field will allow Ops Manager to implement TLS secure communications.
10. Select **Keep Unreachable Director VMs** if you want to preserve BOSH Director VMs after a failed deployment for troubleshooting purposes.

11. (Optional) Select **HM Pager Duty Plugin** to enable Health Monitor integration with PagerDuty.

☒ HM Pager Duty Plugin

Service Key*

HTTP Proxy

- **Service Key:** Enter your API service key from PagerDuty.
- **HTTP Proxy:** Enter an HTTP proxy for use with PagerDuty.

12. (Optional) Select **HM Email Plugin** to enable Health Monitor integration with email.

☒ HM Email Plugin

Host*

Port*

Domain*

From*

Recipients*

Username

Password

☒ Enable TLS

- **Host:** Enter your email hostname.
- **Port:** Enter your email port number.
- **Domain:** Enter your domain.
- **From:** Enter the address for the sender.
- **Recipients:** Enter comma separated addresses of intended recipients.
- **Username:** Enter the username for your email server.
- **Password:** Enter your username's password.
- **Enable TLS:** Select this checkbox to enable Transport Layer Security.

13. For **CredHub Encryption Provider**, you can choose whether BOSH CredHub stores its encryption key internally on the BOSH Director and CredHub VM, or in an external hardware security module (HSM). The HSM option is more secure.

Before configuring an HSM encryption provider in the **Director Config** pane, you must follow the procedures and collect information described in [Preparing CredHub HSMs for Configuration](#).

 **Note:** After you deploy Ops Manager with an HSM encryption provider, you cannot change BOSH CredHub to store encryption keys internally.

CredHub Encryption Provider

☒ Internal
 ☐ Luna HSM

Encryption Key Name*

Provider Partition*

Provider Partition Password*

Provider Client Certificate*

Provider Client Certificate Private Key*

HSM Host Address*

HSM Port Address*

Partition Serial Number*

HSM Certificate*

- **Internal:** Select this option for internal CredHub key storage. This option is selected by default and requires no additional configuration.
- **Luna HSM:** Select this option to use a SafeNet Luna HSM as your permanent CredHub encryption provider, and fill in the following fields:
 1. **Encryption Key Name:** Any name to identify the key that the HSM uses to encrypt and decrypt the CredHub data. Changing this key name after you deploy Ops Manager can cause service downtime.
 2. **Provider Partition:** The partition that stores your encryption key. Changing this partition after you deploy Ops Manager could cause service downtime. For this value and the ones below, use values gathered in [Preparing CredHub HSMs for Configuration](#).
 3. **Provider Partition Password**
 4. **Provider Client Certificate:** The certificate that validates the identity of the HSM when CredHub connects as a client.
 5. **Provider Client Certificate Private Key**
 6. **HSM Host Address**
 7. **HSM Port Address:** If you do not know your port address, enter `1792`.
 8. **Partition Serial Number**
 9. **HSM Certificate:** The certificate that the HSM presents to CredHub to establish a two-way mTLS connection.

14. Select a **Blobstore Location** to either configure the blobstore as an internal server or an external endpoint. Because the internal server is unscalable and less secure, Pivotal recommends that you configure an external blobstore.

 **Note:** After you deploy Ops Manager, you cannot change the blobstore location.

Blobstore Location

☒ Internal
☐ S3 Compatible Blobstore

S3 Endpoint*

Bucket Name*

Access Key*

Secret Key*

☒ V2 Signature
☐ V4 Signature

Region*

☐ GCS Blobstore

Bucket Name*

Storage Class*

Regional

Service Account Key*

- o **Internal:** Select this option to use an internal blobstore. Ops Manager creates a new VM for blob storage. No additional configuration is required.
- o **S3 Compatible Blobstore:** Select this option to use an external S3-compatible endpoint. When you have created an S3 bucket, complete the following steps:
 1. **S3 Endpoint:** Navigate to the [Regions and Endpoints](#) topic in the AWS documentation.
 - a. Locate the endpoint for your region in the **Amazon Simple Storage Service (S3)** table and construct a URL using your region's endpoint. For example, if you are using the `us-west-2` region, the URL you create would be `https://s3-us-west-2.amazonaws.com`. Enter this URL into the **S3 Endpoint** field.
 - b. On a command line, run `ssh ubuntu@OPS-MANAGER-FQDN` to SSH into the Ops Manager VM. Replace `OPS-MANAGER-FQDN` with the fully qualified domain name of Ops Manager.
 - c. Copy the custom public CA certificate you used to sign the S3 endpoint into `/etc/ssl/certs` on the Ops Manager VM.
 - d. On the Ops Manager VM, run `sudo update-ca-certificates -f -v` to import the custom CA certificate into the Ops Manager VM truststore.

 **Note:** You must also add this custom CA certificate into the **Trusted Certificates** field in the **Security** page. See [Security Page](#) for instructions.

2. **Bucket Name:** Enter the name of the S3 bucket.
3. **Access Key** and **Secret Key:** Enter the keys you generated when creating your S3 bucket.
4. Select **V2 Signature** or **V4 Signature**. If you select **V4 Signature**, enter your **Region**.

 **Note:** AWS recommends using Signature Version 4. For more information about AWS S3 Signatures, see [Authenticating Requests](#) in the AWS documentation.

- **Enable TLS:** Select this checkbox to enable TLS.

 **Note:** If you are using Linux stemcells, make sure you have configured [Linux stemcell v3586.16 or later](#) for all tiles before enabling TLS.

 **Note:** If you are using PAS for Windows 2016, make sure you have configured [Windows stemcell v1709.10 or later](#) for all tiles before enabling TLS.

- **GCS Blobstore:** Select this option to use an external GCS endpoint. To create a GCS bucket, you must have a GCS account. Follow the procedures in [Creating Storage Buckets](#) in the GCS documentation to create a GCS bucket. When you have created a GCS bucket, complete the following steps:
 1. **Bucket Name:** Enter the name of your GCS bucket.
 2. **Storage Class:** Select the storage class for your GCS bucket. See [Storage Classes](#) in the GCP documentation for more information.
 3. **Service Account Key:** Follow the steps in the [Set up an IAM Service Account](#) section of *Preparing to Deploy Ops Manager on GCP Manually* to download a JSON file with a private key. Enter the contents of the JSON file into the field.

15. For **Database Location**, select **External MySQL Database** and complete the following steps:

Database Location

☒ Internal

☐ External MySQL Database

Host*

Port*

Username*

Password*

Database*

- From the AWS Console, navigate to the RDS Dashboard.
- Select **Instances**, then click the arrow to the left of your instance and select the second icon to display the **Details** information.
- Refer to the following table to retrieve the values for the **Director Config** page:

| RDS Instance Field | BOSH Director Field |
|--------------------|--|
| Endpoint | Host |
| Port | Port, which is <code>3306</code> . |
| DB Name | Database, which is <code>bosh</code> . |
| Username | Username |

- For **Password**, enter the password that you defined for your MySQL database when you created in the [Step 19: Create a MySQL Database using AWS RDS](#) section of the *Installing PCF on AWS Manually* topic. In addition, if you selected the **Enable TLS for Director Database** checkbox, you can fill out the following optional fields:
- **Enable TLS:** Selecting this checkbox enables TLS communication between the BOSH Director and the database.

- **TLS CA:** Enter the Certificate Authority for the TLS Certificate.
- **TLS Certificate:** Enter the client certificate for mutual TLS connections to the database.
- **TLS Private Key:** Enter the client private key for mutual TLS connections to the database.
- **Advanced DB Connection Options:** If you would like to provide additional options for the database, use this field to provide a JSON-formatted options string.

- (Optional) **Director Workers** sets the number of workers available to execute Director tasks. This field defaults to 5.
- (Optional) **Max Threads** sets the maximum number of threads that the BOSH Director can run simultaneously. For AWS, the default value is 6. Leave this field blank to use this default value. Pivotal recommends that you use the default value unless doing so results in rate limiting or errors on your IaaS.
- (Optional) To add a custom URL for your BOSH Director, enter a valid hostname in **Director Hostname**. You can also use this field to configure [a load balancer in front of your BOSH Director](#).

Warning: In Ops Manager v2.2.7 and earlier, if you change the **Director Hostname** after your initial deployment, you can cause downtime. Changing the hostname triggers all VMs to be recreated. This issue is resolved in [Ops Manager v2.2.8](#) and later.

- (Optional) Enter your list of comma-separated **Excluded Recursors** to declare which IP addresses and ports should not be used by the DNS server.
- (Optional) To disable BOSH DNS, select the **Disable BOSH DNS server for troubleshooting purposes** checkbox. For more information about the BOSH DNS service discovery mechanism, see [BOSH DNS Enabled by Default](#) in the Ops Manager v2.2 Release Notes.

Breaking Change: Do not disable BOSH DNS without consulting Pivotal Support.

- (Optional) To set a custom banner that users see when logging in to the Director using SSH, enter text in the **Custom SSH Banner** field.

☐ Disable BOSH DNS server for troubleshooting purposes

Custom SSH Banner

- (Optional) Enter your comma-separated custom **Identification Tags**. For example, `iaas:foundation1, hello:world`. You can use the tags to identify your foundation when viewing VMs or disks from your IaaS.
- Click **Save**.

Step 4: Create Availability Zones Page

Note: Pivotal recommends at least three availability zones (AZs) for a highly available installation of PAS. The procedures in [Installing PCF on AWS Manually](#) use 3 AZs.

- Select **Create Availability Zones**.

Create Availability Zones

Availability Zones

Add

▼ us-west-1c

Amazon Availability Zone*

us-west-1c

The Amazon Availability Zone name (ex: 'us-east-1b')

Save

2. To add the three AZs you specified in the [Step 4: Create a VPC](#) section of the *Installing PCF on AWS Manually* topic, do the following:
 - a. Click **Add**.
 - b. For **Amazon Availability Zone**, enter the name of the AZ.
 - c. Repeat until you have entered all three AZs, in the format `REGION-#a`, `REGION-#b`, and `REGION-#c`. For example, `us-west-2a`, `us-west-2b`, and `us-west-2c`.
3. Click **Save**.

Step 5: Create Networks Page

Create Networks

Warning: Pivotal recommends keeping the IP settings throughout the life of your installation. Ops Manager may prevent you from changing them in the future.
Contact Pivotal support for help completing such a change.

Verification Settings

☐ Enable ICMP checks

Networks

One or many IP ranges upon which your products will be deployed

▼ Infrastructure 🗑️

Name*

Add Network

Subnets

Add Subnet

VPC Subnet ID*

CIDR*

Reserved IP Ranges

DNS*

Gateway*

Availability Zones*

☒ us-west-2a

☐ us-west-2b

☐ us-west-2c

1. Select **Create Networks**.
2. (Optional) Select **Enable ICMP checks** to enable ICMP on your networks. Ops Manager uses ICMP checks to confirm that components within your network are reachable.
3. Perform the following steps to add the network configuration that you created for your VPC in the [Create a VPC](#) section of *Installing PCF on AWS Manually*. Record your VPC CIDR if you set a CIDR other than the recommendation!
 - a. Click **Add Network**.
 - b. For **Name**, enter `infrastructure`.
 - c. Create a subnet for each availability zone by clicking **Add Subnet**. Refer to the table below for the information required to create all three subnets:

| | | |
|--------------|--------------------|--|
| First Subnet | VPC Subnet ID | <code>pcf-infrastructure-subnet-az0</code> |
| | CIDR | <code>10.0.16.0/28</code> |
| | Reserved IP Ranges | <code>10.0.16.0-10.0.16.4</code> |
| | DNS | <code>10.0.0.2</code> * |
| | Gateway | <code>10.0.16.1</code> |
| | Availability Zones | REGION-#a . For example, <code>us-west-2a</code> . |

| | | |
|---------------|--------------------|-------------------------------------|
| Second Subnet | VPC Subnet ID | pcf-infrastructure-subnet-az1 |
| | CIDR | 10.0.16.16/28 |
| | Reserved IP Ranges | 10.0.16.16-10.0.16.20 |
| | DNS | 10.0.0.2 * |
| | Gateway | 10.0.16.17 |
| Third Subnet | Availability Zones | REGION-#b . For example, us-west-2b |
| | VPC Subnet ID | pcf-infrastructure-subnet-az2 |
| | CIDR | 10.0.16.32/28 |
| | Reserved IP Ranges | 10.0.16.32-10.0.16.36 |
| | DNS | 10.0.0.2 * |
| | Gateway | 10.0.16.33 |
| | Availability Zones | REGION-#c . For example, us-west-2c |

* If you set a VPC CIDR other than recommended, enter the second IP in your VPC CIDR. For example, for a 10.0.0.0/24 VPC CIDR, enter 10.0.0.2 in each subnet.

- d. Click **Add Network**.
- e. For **Name**, enter the name of your runtime. For example, pas .
- f. Create a subnet for each availability zone by clicking **Add Subnet**. See the table below for the information required to create all three subnets:

| | | |
|---------------|--------------------|-------------------------------------|
| First Subnet | VPC Subnet ID | pcf-pas-subnet-az0 |
| | CIDR | 10.0.4.0/24 |
| | Reserved IP Ranges | 10.0.4.0-10.0.4.4 |
| | DNS | 10.0.0.2 * |
| | Gateway | 10.0.4.1 |
| | Availability Zones | REGION-#a . For example, us-west-2a |
| Second Subnet | VPC Subnet ID | pcf-pas-subnet-az1 |
| | CIDR | 10.0.5.0/24 |
| | Reserved IP Ranges | 10.0.5.0-10.0.5.4 |
| | DNS | 10.0.0.2 * |
| | Gateway | 10.0.5.1 |
| | Availability Zones | REGION-#b . For example, us-west-2b |
| Third Subnet | VPC Subnet ID | pcf-pas-subnet-az2 |
| | CIDR | 10.0.6.0/24 |
| | Reserved IP Ranges | 10.0.6.0-10.0.6.4 |
| | DNS | 10.0.0.2 * |
| | Gateway | 10.0.6.1 |
| | Availability Zones | REGION-#c . For example, us-west-2c |

* If you set a VPC CIDR other than recommended, enter the second IP in your VPC CIDR. For example, for a 10.0.0.0/24 VPC CIDR, enter 10.0.0.2 in each subnet.

- g. Click **Add Network**.
- h. For **Name**, enter services .
- i. Create a subnet for each availability zone by clicking **Add Subnet**. Refer to the table below for the information required to create all three subnets:

| | | |
|--------------|--------------------|---------------------------------------|
| First Subnet | VPC Subnet ID | pcf-services-subnet-az0 |
| | CIDR | 10.0.8.0/24 |
| | Reserved IP Ranges | 10.0.8.0-10.0.8.3 |
| | DNS | 10.0.0.2 * |
| | Gateway | 10.0.8.1 |
| | Availability Zones | REGION-#a . For example, us-west-2a . |

| | | |
|---------------|--------------------|---------------------------------------|
| Second Subnet | VPC Subnet ID | pcf-services-subnet-az1 |
| | CIDR | 10.0.9.0/24 |
| | Reserved IP Ranges | 10.0.9.0-10.0.9.3 |
| | DNS | 10.0.0.2 * |
| | Gateway | 10.0.9.1 |
| | Availability Zones | REGION-#b . For example, us-west-2b . |
| Third Subnet | VPC Subnet ID | pcf-services-subnet-az2 |
| | CIDR | 10.0.10.0/24 |
| | Reserved IP Ranges | 10.0.10.0-10.0.10.3 |
| | DNS | 10.0.0.2 * |
| | Gateway | 10.0.10.1 |
| | Availability Zones | REGION-#c . For example, us-west-2c . |

* If you set a VPC CIDR other than recommended, enter the second IP in your VPC CIDR. For example, for a 10.0.0.0/24 VPC CIDR, enter 10.0.0.2 in each subnet.

- Click **Save**.

 **Note:** If you are deploying PKS with a PKS workload load balancer, you must tag each AWS subnet with your PKS Kubernetes cluster unique identifier before you create the load balancer. For more information about tagging subnets with a PKS cluster unique identifier, see [AWS Prerequisites](#).

 **Note:** After you deploy Ops Manager, you add subnets with overlapping Availability Zones to expand your network. For more information about configuring additional subnets, see [Expanding Your Network with Additional Subnets](#).

Step 6: Assign AZs and Networks

- Select **Assign AZs and Networks**.

Assign AZs and Networks

The BOSH Director is a single instance.

Choose the availability zone in which to place that instance. It is highly recommended that you backup this VM on a regular basis to preserve settings.

Singleton Availability Zone

AZ-MGMT

Network

infrastructure

Save

- Use the dropdown to select a **Singleton Availability Zone**. The BOSH Director is deployed into this AZ.
- Use the dropdown to select **infrastructure** under **Network**. The BOSH Director is deployed into this network.
- Click **Save**.

Step 7: Security Page

[illegible]

1. Select **Security**.
2. In **Trusted Certificates**, enter your custom certificate authority (CA) certificates to insert into your organization's certificate trust chain. This feature enables all BOSH-deployed components in your deployment to trust custom root certificates.

To enter multiple certificates, paste your certificates one after the other. For example, format your certificates like the following:

```

-----BEGIN CERTIFICATE-----
ABCEDEFGH12345678ABCEDEFGH12345678ABCEDEFGH12345678AB
EFGH12345678ABCEDEFGH12345678ABCEDEFGH12345678ABCEDEF
GH12345678ABCEDEFGH12345678ABCEDEFGH12345678...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
BCDEFGH12345678ABCEDEFGH12345678ABCEDEFGH12345678ABB
EFGH12345678ABCEDEFGH12345678ABCEDEFGH12345678ABCEDEF
GH12345678ABCEDEFGH12345678ABCEDEFGH12345678...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
CDEFGH12345678ABCEDEFGH12345678ABCEDEFGH12345678ABBB
EFGH12345678ABCEDEFGH12345678ABCEDEFGH12345678ABCEDEF
GH12345678ABCEDEFGH12345678ABCEDEFGH12345678...
-----END CERTIFICATE-----

```

 Note: If you want to use Docker Registries for running app instances in Docker containers, enter the certificate for your private Docker Registry in this field. See [Using Docker Registries](#) for more information on running app instances in PAS using Docker Registries.

3. Choose **Generate passwords** or **Use default BOSH password**. Pivotal recommends that you use the **Generate passwords** option for greater security.
4. Click **Save**. To view your saved Director password, click the **Credentials** tab.

Step 8: Syslog Page

1. Select **Syslog**.

Syslog

Do you want to configure Syslog for Bosh Director?

☐ No
 ☒ Yes

Address*

The address or host for the syslog server

Port*

Transport Protocol*

TCP

⌵

☐ Enable TLS

Permitted Peer*

SSL Certificate*

Save

- (Optional) Select **Yes** to send BOSH Director system logs to a remote server.
- In the **Address** field, enter the IP address or DNS name for the remote server.
- In the **Port** field, enter the port number that the remote server listens on.
- In the **Transport Protocol** dropdown menu, select **TCP**, **UDP**, or **REL**. This selection determines which transport protocol is used to send the logs to the remote server.
- (Optional) Pivotal strongly recommends that you enable TLS encryption when forwarding logs as they may contain sensitive information. For example, these logs may contain cloud provider credentials. To enable TLS, perform the following steps.
 - In the **Permitted Peer** field, enter either the name or SHA1 fingerprint of the remote peer.
 - In the **SSL Certificate** field, enter the SSL certificate for the remote server.
- Click **Save**.

Step 9: Resource Config Page

- Select **Resource Config**.

| JOB | INSTANCES | PERSISTENT DISK TYPE | VM TYPE | LOAD BALANCERS | INTERNET CONNECTED |
|------------------------|--------------|----------------------|---|----------------|-------------------------------------|
| BOSH Director | Automatic: 1 | Automatic: 50 GB | Automatic: large.disk (cpu: 2, ram: 8 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| Master Compilation Job | 1 | None | small (cpu: 1, ram: 2 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |

[Save](#)

- Adjust any values as necessary for your deployment. Under the **Instances**, **Persistent Disk Type**, and **VM Type** fields, choose **Automatic** from the dropdown to allocate the recommended resources for the job. If the **Persistent Disk Type** field reads **None**, the job does not require persistent disk space.

Note: Pivotal recommends provisioning a BOSH Director VM with at least 8 GB memory.

Note: If you set a field to **Automatic** and the recommended resource allocation changes in a future version, Ops Manager automatically uses the new recommended allocation.

Note: If you install PAS for Windows, provision your **Master Compilation Job** with at least 128 GB of disk space.

- (Optional) Enter your AWS target group name in the **Load Balancers** column for each job. Prepend the name with `alb:`. For example, enter `alb:target-group-name`. To create an Application Load Balancer (ALB) and target group, follow the procedures in [Getting Started with Application Load Balancers](#) in the AWS documentation. Then navigate to **Target Groups** in the **EC2 Dashboard** menu to find your target group **Name**.

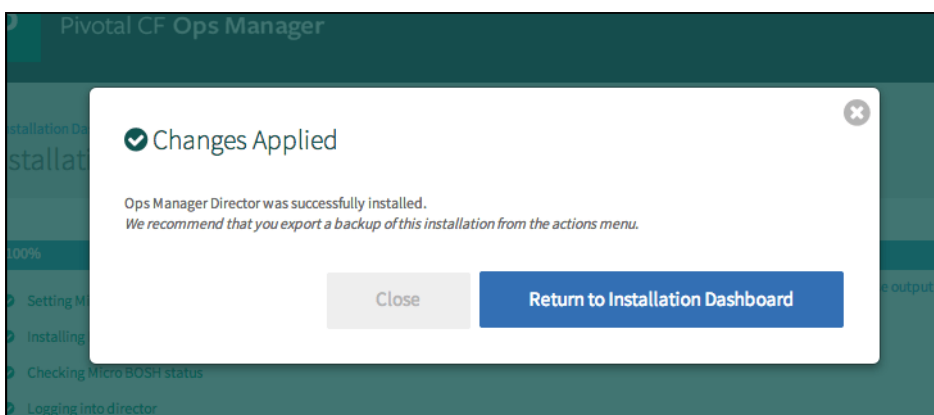

Note: To configure an ALB, you must have the following AWS IAM permissions.

```
"elasticloadbalancing:DescribeLoadBalancers",
"elasticloadbalancing:DeregisterInstancesFromLoadBalancer",
"elasticloadbalancing:RegisterInstancesWithLoadBalancer",
"elasticloadbalancing:DescribeTargetGroups",
"elasticloadbalancing:RegisterTargets"
```

- Click **Save**.

Step 10: Complete the BOSH Director Installation

- Return to the **Installation Dashboard**.
- Click **Apply Changes**.
- BOSH Director begins to install. The **Changes Applied** window displays when the installation process successfully completes.

Next Steps

After completing the procedures in this topic, you must configure a runtime for PCF. You can install PCF on AWS with the Pivotal Application Service (PAS) or Pivotal Container Service (PKS) runtime.

To configure a runtime, do one of the following:

- Configure PAS. See [Deploying PAS on AWS Using Terraform](#).
- Configure PKS. See [Installing PKS on AWS](#) [↗](#).

Deploying PAS on AWS

Page last updated:

This topic describes how to configure Pivotal Application Service (PAS) components as part of deploying [Pivotal Cloud Foundry](#) (PCF) on Amazon Web Services (AWS).

Before beginning this procedure, ensure that you have successfully completed all steps in the [Installing PCF on AWS Manually](#) and [Configuring BOSH Director on AWS](#).

Note: If you plan to [install the PCF IPsec add-on](#), you must do so before installing any other tiles. Pivotal recommends installing IPsec immediately after Ops Manager, and before installing the PAS Runtime tile.

Step 1: Add PAS to Ops Manager

1. If you have not already downloaded PAS, log in to [Pivotal Network](#), and click on PAS.
2. From the **Releases** dropdown, select the release to install and choose one of the following:
 - a. Click PAS download the PAS `.pivotal` file.
 - b. Click **PCF Small Footprint Runtime** to download the Small Footprint Runtime `.pivotal` file. For more information, see [Getting Started with Small Footprint Runtime](#).
3. Navigate to the Pivotal Cloud Foundry Operations Manager Installation Dashboard.
4. Click **Import a Product** to add your tile to Ops Manager. For more information, refer to the [Adding and Deleting Products](#) topic.
5. Click the PAS tile in the Installation Dashboard.

Step 2: Assign Availability Zones and Networks

1. Select **Assign AZs and Networks**. These are the Availability Zones that you create when configuring BOSH Director.

AZ and Network Assignments

Place singleton jobs in

☒ us-west-2a
☐ us-west-2b
☐ us-west-2c

Balance other jobs in

☒ us-west-2a
☒ us-west-2b
☒ us-west-2c

Network

docs-exploration-ert-network

Save

2. Select an Availability Zone under **Place singleton jobs**. Ops Manager runs any job with a single instance in this Availability Zone.
3. Select all Availability Zones under **Balance other jobs**. Ops Manager balances instances of jobs with more than one instance across the Availability Zones that you specify.

 **Note:** Pivotal recommends at least three Availability Zones for a highly available installation of PAS.

4. For **Network**, select the `pas` network that you created in the [Step 5: Create Networks Page](#) section of the *Configuring BOSH Director on AWS* topic.
5. Click **Save**.

Step 3: Configure Domains

1. Select **Domains**.

Application Service hosts applications at subdomains under its apps domain and assigns system components to subdomains under its system domain. You need to configure a wildcard DNS for both the apps domain and system domain. The two domains can be the same, although this is not recommended.

System Domain *

sys.metallicseaweed.cf-app.com

Apps Domain *

apps.metallicseaweed.cf-app.com

Save

2. Enter the system and application domains.
 - The **System Domain** defines your target when you push apps to PAS. This the `system.YOUR-SYSTEM-DOMAIN.com` domain that you created in [Installing PCF on AWS Manually](#).
 - The **Apps Domain** defines where PAS should serve your apps. This the `apps.YOUR-SYSTEM-DOMAIN.com` domain that you created in [Installing PCF on AWS Manually](#).
3. Click **Save**.

Step 4: Configure Networking

1. Select **Networking**.

2. Leave the **Router IPs**, **SSH Proxy IPs**, **HAProxy IPs**, and **TCP Router IPs** fields blank. You do not need to complete these fields when deploying PCF to AWS with Elastic Load Balancers (ELBs).

Note: You specify load balancers in the **Resource Config** section of Pivotal Application Service (PAS) later in the installation process. See the [Configure Router to Elastic Load Balancer](#) section of this topic for more information.

3. Under **Certificates and Private Key for HAProxy and Router**, you must provide at least one **Certificate and Private Key** name and certificate keypair for HAProxy and Gorouter. The HAProxy and Gorouter are enabled to receive TLS communication by default. You can configure multiple certificates for HAProxy and Gorouter.
 - a. Click the **Add** button to add a name for the certificate chain and its private keypair. This certificate is the default used by Gorouter and HAProxy.

Certificates and Private Keys for HAProxy and Router

example-cert

Name *

example-cert

A human-readable name describing the use of this certificate.

Certificate and Private Key for HAProxy and Router *

```
-----BEGIN CERTIFICATE-----
MIIE...
-----END CERTIFICATE-----
-----BEGIN RSA PRIVATE KEY-----
...
-----END RSA PRIVATE KEY-----
```

[Generate RSA Certificate](#)

example-cert-2

Name *

example-cert-2

Certificate and Private Key for HAProxy and Router *

```
-----BEGIN CERTIFICATE-----
MIIE...
-----END CERTIFICATE-----
-----BEGIN RSA PRIVATE KEY-----
...
-----END RSA PRIVATE KEY-----
```

You can either provide a certificate signed by a Certificate Authority (CA) or click on the **Generate RSA Certificate** link to generate a self-signed certificate in Ops Manager.

- b. If you want to configure multiple certificates for HAProxy and Gorouter, click the **Add** button and fill in the appropriate fields for each additional certificate keypair.

For details about generating certificates in Ops Manager for your wildcard system domains, see the [Providing a Certificate for Your SSL/TLS Termination Point](#) topic.

Note: If you configured Ops Manager Front End without a certificate, you can use this new certificate to complete Ops Manager configuration. To configure your Ops Manager Front End certificate, see `Configure Front End` in [Preparing to Deploy Ops Manager on GCP Manually](https://docs.pivotal.io/pcf/om/2-2/gcp/prepare-env-manual.html#config-frontend).

Note: Ensure that you add any certificates that you generate in this pane to your infrastructure load balancer.

4. (Optional) When validating client requests using mutual TLS, the Gorouter trusts multiple certificate authorities (CAs) by default. If you want to configure the Gorouter and HAProxy to trust additional CAs, enter your CA certificates under **Certificate Authorities Trusted by Router and HAProxy**. All CA certificates should be appended together into a single collection of PEM-encoded entries.

Certificate Authorities Trusted by Router and HAProxy

In addition to well-known, public CAs, and those trusted via the BOSH trusted certificates collection, these certificates can be used to validate the certificates from incoming client requests. All CA certificates should be appended together into a single collection of PEM-encoded entries.

- In the **Minimum version of TLS supported by HAProxy and Router** field, select the minimum version of TLS to use in HAProxy and Gorouter communications. HAProxy and Gorouter use TLS v1.2 by default. If you need to accommodate clients that use an older version of TLS, select a lower minimum version. For a list of TLS ciphers supported by the Gorouter, see [Securing Traffic into Cloud Foundry](#).

Minimum version of TLS supported by HAProxy and Router*

- ☐ TLSv1.0
- ☐ TLSv1.1
- ☒ TLSv1.2

- Configure **Logging of Client IPs in CF Router**. The **Log client IPs** option is set by default. To comply with the General Data Protection Regulation (GDPR), select one of the following options to disable logging of client IP addresses:

- If your load balancer exposes its own source IP address, disable logging of the `X-Forwarded-For` HTTP header only.
- If your load balancer exposes the source IP of the originating client, disable logging of both the source IP address and the `X-Forwarded-For` HTTP header.

Logging of Client IPs in CF Router*

- ☒ Log client IPs
- ☐ Disable logging of X-Forwarded-For header only
- ☐ Disable logging of both source IP and X-Forwarded-For header
- To comply with GDPR, select one of the options to disable logging of client IPs. If the source IP exposed by your load balancer is its own, choose to disable logging of XFF header only. If the source IP exposed by your load balancer is that of the downstream client, choose to disable logging of the source IP also.

- Under **Configure support for the X-Forwarded-Client-Cert header**, configure PCF handles `x-forwarded-client-cert` (XFCC) HTTP headers based on where TLS is terminated for the first time in your deployment.

Configure support for the X-Forwarded-Client-Cert header. This header can be used by applications to verify the requester via mutual TLS. The option you should select depends upon where you will be terminating the TLS connection for the first time. *

- ☒ TLS terminated for the first time at infrastructure load balancer
- ☐ TLS terminated for the first time at HAProxy
- ☐ TLS terminated for the first time at the Router

The following table

indicates which option to choose based on your deployment layout.

| If your deployment is configured as follows: | Then select the following option: | Additional notes: |
|--|--|---|
| <ul style="list-style-type: none"> The Load Balancer is terminating TLS, and Load balancer is configured to put the client certificate from a mutual authentication TLS handshake into the X-Forwarded-Client-Cert HTTP header | TLS terminated for the first time at infrastructure load balancer (default). | Both HAProxy and the Gorouter forward the XFCC header when included in the request. |
| <ul style="list-style-type: none"> The Load Balancer is configured to pass through the TLS handshake via TCP to | TLS terminated for | HAProxy sets the XFCC header with the client certificate received in the TLS handshake. The Gorouter forwards the header. |

| | | |
|--|--|---|
| <ul style="list-style-type: none"> the instances of HAProxy, and HAProxy instance count is > 0 | the first time at HAProxy. |  Breaking Change: In the Router behavior for Client Certificates field, you cannot select the Router does not request client certificates option. |
| <ul style="list-style-type: none"> The Load Balancer is configured to pass through the TLS handshake via TCP to instances of the Gorouter | TLS terminated for the first time at the Gorouter. | <p>The Gorouter strips the XFCC header if it is included in the request and forwards the client certificate received in the TLS handshake in a new XFCC header.</p> <p>If you have deployed instances of HAProxy, app traffic bypasses those instances in this configuration. If you have also configured your load balancer to route requests for ssh directly to the Diego Brain, consider reducing HAProxy instances to 0.</p>  Breaking Change: In the Router behavior for Client Certificates field, you cannot select the Router does not request client certificates option. |

For a description of the behavior of each configuration option, see [Forward Client Certificate to Applications](#).

8. To configure HAProxy to handle client certificates, select one of the following options in the **HAProxy behavior for Client Certificate Validation** field.

HAProxy behavior for Client Certificate Validation*

- ☒ HAProxy does not request client certificates.
- ☐ HAProxy requests but does not require client certificates. This option is necessary if you want to enable mTLS for applications and TLS is terminated for the first time at HAProxy

- HAProxy does not request client certificates.** This option requires mutual authentication, which makes it incompatible with XFCC option **TLS terminated for the first time at HAProxy**. HAProxy does not request client certificates, so the client does not provide them and no validation occurs. This is the default configuration.
- HAProxy requests but does not require client certificates.** The HAProxy requests client certificates in TLS handshakes, validates them when presented, but does not require them.

 **warning:** Upon upgrade, PAS will fail to receive requests if your load balancer is configured to present a client certificate in the TLS handshake with HAProxy but HAProxy has not been configured with the certificate authority used to sign it. To mitigate this issue, select **HAProxy does not request client certificates** in the **Networking** pane or configure the HAProxy with the appropriate CA.

9. To configure Gorouter behavior for handling client certificates, select one of the following options in the **Router behavior for Client Certificate Validation** field.

Router behavior for Client Certificate Validation*

- ☐ Router does not request client certificates. This option is incompatible with XFCC options "TLS terminated for the first time at HAProxy" and "TLS terminated for the first time at the Router" because these options require mutual authentication.
- ☒ Router requests but does not require client certificates.
- ☐ Router requires client certificates.

- Router does not request client certificates.** This option is incompatible with the XFCC configuration options **TLS terminated for the first time at HAProxy** and **TLS terminated for the first time at the Router** in PAS because these options require mutual authentication. As client certificates are not requested, client will not provide them, and thus validation of client certificates will not occur.
- Router requests but does not require client certificates.** The Gorouter requests client certificates in TLS handshakes, validates them when presented, but does not require them. This is the default configuration.
- Router requires client certificates.** The Gorouter validates that the client certificate is signed by a Certificate Authority that the Gorouter trusts. If the Gorouter cannot validate the client certificate, the TLS handshake fails.

 **warning:** Requests to the platform will fail upon upgrade if your load balancer is configured with client certificates and the Gorouter does not have the certificate authority. To mitigate this issue, select **Router does not request client certificates** for **Router behavior for Client**

Certificate Validation in the **Networking** pane.

- In the **TLS Cipher Suites for Router** field, review the TLS cipher suites for TLS handshakes between Gorouter and front-end clients such as load balancers or HAProxy. The default value for this field is `ECDHE-RSA-AES128-GCM-SHA256:TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384`.

 **Note:** AWS Classic Load Balancers do not support PCF's default cipher suites. See [TLS Cipher Suite Support by AWS Load Balancers](#) for information about configuring your AWS load balancers and Gorouter.

If you want to modify the default configuration, use an ordered, colon-delimited list of Golang-supported TLS cipher suites in the OpenSSL format. Operators should verify that the ciphers are supported by any clients or front-end components that will initiate TLS handshakes with Gorouter. For a list of TLS ciphers supported by Gorouter, see [Securing Traffic into Cloud Foundry](#).

TLS Cipher Suites for Router *

ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384

Verify that every client participating in TLS handshakes with Gorouter has at least one cipher suite in common with Gorouter.

 **Note:** Specify cipher suites that are supported by the versions configured in the **Minimum version of TLS supported by HAProxy and Router** field.

- In the **TLS Cipher Suites for HAProxy** field, review the TLS cipher suites for TLS handshakes between HAProxy and its clients such as load balancers and Gorouter. The default value for this field is the following:

`DHE-RSA-AES128-GCM-SHA256:DHE-RSA-AES256-GCM-SHA384:ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384` If you want to modify the default configuration, use an ordered, colon-delimited list of TLS cipher suites in the OpenSSL format.

Operators should verify that the ciphers are supported by any clients or front-end components that will initiate TLS handshakes with HAProxy.

TLS Cipher Suites for HAProxy *

DHE-RSA-AES128-GCM-SHA256:DHE-RSA-AES256-GCM-SHA384:ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384

Verify that every client participating in TLS handshakes with HAProxy has at least one cipher suite in common with HAProxy.

 **Note:** Specify cipher suites that are supported by the versions configured in the **Minimum version of TLS supported by HAProxy and Router** field.

- Under **HAProxy forwards requests to Router over TLS**, select **Enable** or **Disable** based on your deployment layout.

HAProxy forwards requests to Router over TLS. When enabled, HAProxy will forward all requests to the Router over TLS. HAProxy will use the CA provided to verify the certificates provided by the Router. *

☒ Enable

Certificate Authority for HAProxy Backend *

You need to provide a certificate authority for the certificate and key provided in the "Certificate and Private Key for HAProxy and Router" field. HAProxy will verify those certificates using this CA when establishing a connection. If you generated that certificate and key using the "Generate RSA Certificate" feature, then your CA is the Ops Manager CA, and can be found by visiting the "/api/v0/certificate_authorities" API endpoint.

☐ Disable

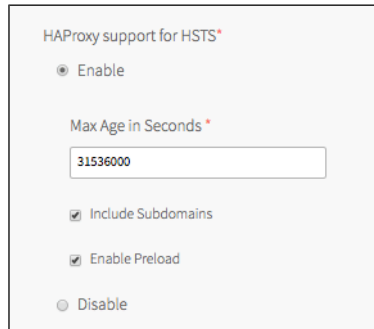

◦ Enable HAProxy forwarding of requests to Router over TLS

| If you want to: | Encrypt communication between HAProxy and the Gorouter |
|-------------------------------|---|
| Then configure the following: | <ol style="list-style-type: none"> 1. Leave Enable selected. 2. In the Certificate Authority for HAProxy Backend field, specify the Certificate Authority (CA) that signed the certificate you configured in the Certificate and Private Key for HAProxy and Router field. <div>  Note: If you used the Generate RSA Certificate link to generate a self-signed certificate, then the CA to specify is the Ops Manager CA, which you can locate at the <code>/api/v0/certificate_authorities</code> endpoint in the Ops Manager API. </div> <ol style="list-style-type: none"> 3. Make sure that Gorouter and HAProxy have TLS cipher suites in common in the TLS Cipher Suites for Router and TLS Cipher Suites for HAProxy fields. |
| See also: | <ul style="list-style-type: none"> ◦ Terminating SSL/TLS at the Load Balancer and Gorouter ◦ Providing a Certificate for Your SSL/TLS Termination Point ◦ Using the Ops Manager API |

◦ Disable HAProxy forwarding of requests to Router over TLS

| If you want to: | Use non-encrypted communication between HAProxy and Gorouter, or you are not using HAProxy |
|-------------------------------|---|
| Then configure the following: | <ol style="list-style-type: none"> 1. Select Disable. 2. If you are not using HAProxy, set the number of HAProxy job instances to <code>0</code> on the Resource Config page. See Disable Unused Resources. |
| See also: | <ul style="list-style-type: none"> ◦ Terminating SSL/TLS at the Gorouter Only ◦ Terminating SSL/TLS at the Load Balancer Only |

13. If you want to force browsers to use HTTPS when making requests to HAProxy, select **Enable** in the **HAProxy support for HSTS** field, and complete

HAProxy support for HSTS*

☒ Enable

Max Age in Seconds*

31536000

☒ Include Subdomains

☒ Enable Preload

☐ Disable

the following optional configuration steps:

- (Optional) Enter a **Max Age in Seconds** for the HSTS request. By default, the age is set to one year. HAProxy will force HTTPS requests from browsers for the duration of this setting.
- (Optional) Select the **Include Subdomains** checkbox to force browsers to use HTTPS requests for all component subdomains.
- (Optional) Select the **Enable Preload** checkbox to force instances of Google Chrome, Firefox, and Safari that access your HAProxy to refer to their built-in lists of known hosts that require HTTPS, of which HAProxy is one. This ensures that the first contact a browser has with your HAProxy is an HTTPS request, even if the browser has not yet received an HSTS header from HAProxy.

- If you are not using SSL encryption or if you are using self-signed certificates, select **Disable SSL certificate verification for this environment**. Selecting this checkbox also disables SSL verification for route services.

 **Note:** For production deployments, Pivotal does not recommend disabling SSL certificate verification.

- (Optional) If you want HAProxy or the Gorouter to reject any HTTP (non-encrypted) traffic, select the **Disable HTTP on HAProxy and Gorouter** checkbox. When selected, HAProxy and Gorouter will not listen on port 80.

☐ Disable HTTP on HAProxy and Gorouter

- (Optional) Select the **Disable insecure cookies on the Router** checkbox to set the secure flag for cookies generated by the router.
- (Optional) To disable the addition of Zipkin tracing headers on the Gorouter, deselect the **Enable Zipkin tracing headers on the router** checkbox. Zipkin tracing headers are enabled by default. For more information about using Zipkin trace logging headers, see [Zipkin Tracing in HTTP Headers](#).
- (Optional) To stop the Router from writing access logs to local disk, deselect the **Enable Router to write access logs locally** checkbox. You should consider disabling this checkbox for high traffic deployments since logs may not be rotated fast enough and can fill up the disk.
- By default, the PAS routers handle traffic for applications deployed to an isolation segment created by the PCF Isolation Segment tile. To configure the PAS routers to reject requests for applications within isolation segments, select the **Routers reject requests for Isolation Segments** checkbox.

☐ Routers reject requests for Isolation Segments

Do not enable this option without deploying

routers for each isolation segment. See the following topics for more information:

- [Installing PCF Isolation Segment](#)
- [Sharding Routers for Isolation Segments](#)

- (Optional) By default, Gorouter support for the PROXY protocol is disabled. To enable the PROXY protocol, select **Enable support for PROXY protocol in CF Router**. When enabled, client-side load balancers that terminate TLS but do not support HTTP can pass along information from the originating client. Enabling this option may impact Gorouter performance. For more information about enabling the PROXY protocol in Gorouter, see the *HTTP Header Forwarding* sections in the [Securing Traffic in Cloud Foundry](#) topic.
- In the **Choose whether to enable route services** section, choose either **Enable route services** or **Disable route services**. Route services are a class of [marketplace services](#) that perform filtering or content transformation on application requests and responses. See the [Route Services](#) topic for details. 1. If you enabled route services, you can also configure the **Bypass security checks for route service lookup** field. Pivotal recommends that you do not enable this field because it has potential security concerns. However, you may need to enable it if your load balancer requires mutual TLS from clients. For more information, see [Configuring Route Service Lookup](#).
- (Optional) If you want to limit the number of app connections to the backend, enter a value in the **Max Connections Per Backend** field. You can use this field to prevent a poorly behaving app from all the connections and impacting other apps.

To choose a value for this field, review the peak concurrent connections received by instances of the most popular apps in your deployment. You can

determine the number of concurrent connections for an app from the `httpStartStop` event metrics emitted for each app request.

If your deployment uses PCF Metrics, you can also obtain this peak concurrent connection information from [Network Metrics](#). The default value is

Max Connections Per Backend *

500

23. Under **Enable Keepalive Connections for Router**, select **Enable** or **Disable**. Keepalive connections are enabled by default. For more information, see [Keepalive Connections](#) in *HTTP Routing*.

Enable Keepalive Connections for Router*

☒ Enable
 ☐ Disable

24. (Optional) To accommodate larger uploads over connections with high latency, increase the number of seconds in the **Router Timeout to Backends** field.
25. (Optional) Use the **Frontend Idle Timeout for Gorouter and HAProxy** field to help prevent connections from your load balancer to Gorouter or HAProxy from being closed prematurely. The value you enter sets the duration, in seconds, that Gorouter or HAProxy maintains an idle open connection from a load balancer that supports keep-alive.

In general, set the value higher than your load balancer's backend idle timeout to avoid the race condition where the load balancer sends a request before it discovers that Gorouter or HAProxy has closed the connection.

See the following table for specific guidance and exceptions to this rule:

| IaaS | Guidance |
|-------|---|
| AWS | AWS ELB has a default timeout of 60 seconds, so Pivotal recommends a value greater than <code>60</code> . |
| Azure | By default, Azure load balancer times out at 240 seconds without sending a TCP RST to clients, so as an exception, Pivotal recommends a value lower than <code>240</code> to force the load balancer to send the TCP RST. |
| GCP | GCP has a default timeout of 600 seconds. For GCP HTTP load balancers, Pivotal recommends a value greater than <code>600</code> . For GCP TCP load balancers, Pivotal recommends a value less than <code>600</code> to force the load balancer to send a TCP RST. |
| Other | Set the timeout value to be greater than that of the load balancer's backend idle timeout. |

 **Note:** Do not set a frontend idle timeout lower than six seconds.

26. (Optional) Increase the value of **Load Balancer Unhealthy Threshold** to specify the amount of time, in seconds, that the router continues to accept connections before shutting down. During this period, healthchecks may report the router as unhealthy, which causes load balancers to failover to other routers. Set this value to an amount greater than or equal to the maximum time it takes your load balancer to consider a router instance unhealthy, given contiguous failed healthchecks.
27. (Optional) Modify the value of **Load Balancer Healthy Threshold**. This field specifies the amount of time, in seconds, to wait until declaring the Router instance started. This allows an external load balancer time to register the Router instance as healthy.

Load Balancer Unhealthy Threshold *

Load Balancer Healthy Threshold *

28. (Optional) If app developers in your organization want certain HTTP headers to appear in their app logs with information from the Gorouter, specify them in the **HTTP Headers to Log** field. For example, to support app developers that deploy Spring apps to PCF, you can enter [Spring-specific HTTP headers](#).

HTTP Headers to Log

29. If you expect requests larger than the default maximum of 16 Kbytes, enter a new value (in bytes) for **HAProxy Request Max Buffer Size**. You may need to do this, for example, to support apps that embed a large cookie or query string values in headers.

30. If your PCF deployment uses HAProxy and you want it to receive traffic only from specific sources, use the following fields:

- **HAProxy Protected Domains:** Enter a comma-separated list of domains to protect from unknown source requests.
- **HAProxy Trusted CIDRs:** Optionally, enter a space-separated list of CIDRs to limit which IP addresses from the **Protected Domains** can send traffic to PCF.

HAProxy Protected Domains

A comma-separated list of domains to protect from requests from unknown sources. Use this property in conjunction with "Trusted CIDRs" to protect these domains from requests from unknown sources.

HAProxy Trusted CIDRs

31. The **Loggregator Port** defaults to if left blank. For AWS environments that are not using an Application Load Balancer, enter .

Container Network Interface Plugin*

 Silk

32. For **Container Network Interface Plugin**, ensure **Silk** is selected and review the following fields:

 **Note:** The **External** option exists to support NSX-T integration for vSphere deployments.

- (Optional) You can change the value in the **Applications Network Maximum Transmission Unit (MTU)** field. Pivotal recommends setting the MTU value for your application network to . Some configurations, such as networks that use GRE tunnels, may require a smaller MTU value.
- (Optional) Enter an IP range for the overlay network in the **Overlay Subnet** box. If you do not set a custom range, Ops Manager uses .

 **warning:** The overlay network IP range must not conflict with any other IP addresses in your network.

- Enter a UDP port number in the **VXLAN Tunnel Endpoint Port** box. If you do not set a custom port, Ops Manager uses 4789.
- For **Denied logging interval**, set the per-second rate limit for packets blocked by either a container-specific [networking policy](#) or by [Application Security Group](#) rules applied across the space, org, or deployment. This field defaults to .
- For **UDP logging interval**, set the per-second rate limit for UDP packets sent and received. This field defaults to .
- To enable logging for app traffic, select **Log traffic for all accepted/denied application packets**. See [Manage Logging for Container-to-Container Networking](#) for more information.
- By default, containers use the same DNS servers as the host. If you want to override the DNS servers to be used in containers, enter a comma-separated list of servers in **DNS Servers**.

 **Note:** If your deployment uses BOSH DNS, which is the default, you cannot use this field to override the DNS servers used in containers.

33. For **DNS Search Domains**, enter DNS search domains as a comma-separated list. Your containers append these search domains to hostnames to resolve them into full domain names.

DNS Search Domains

DNS search domains to be used in containers. A comma-separated list can be specified.

34. For **Database Connection Timeout**, set the connection timeout for clients of the policy server and silk databases. The default value is . You may need to increase this value if your deployment experiences timeout issues related to Container-to-Container Networking.

35. (Optional) TCP Routing is disabled by default. You should enable this feature if your DNS sends TCP traffic through a load balancer rather than directly to a TCP router. To enable TCP routing:
 - a. Select **Enable TCP Routing**
 - b. For **TCP Routing Ports**, enter a single port or a range of ports for the load balancer to forward to. If you [configured AWS for PCF manually](#), enter `1024-1123` which corresponds to the rules you created for `pcf-tcp-elb`.
 - To support multiple TCP routes, Pivotal recommends allocating multiple ports.
 - To allocate a list of ports rather than a range:
 1. Enter a single port in the **TCP Routing Ports** field.
 2. After deploying PAS, follow the directions in [Configuring a List of TCP Routing Ports](#) to add TCP routing ports using the cf CLI.
 - c. For AWS, you also need to specify the name of a TCP ELB in the **LOAD BALANCER** column of TCP Router job of the `Resource Config` screen. You configure this later on in PAS. For more information, see the [Configure Router to Elastic Load Balancer](#) topic.

Enable TCP requests to your apps via specific ports on the TCP router. You will want to configure a load balancer to forward these TCP requests to the TCP routers. If you do not have a load balancer, then you can also send traffic directly to the TCP router.*

☐ Select this option if you prefer to enable TCP Routing at a later time

☒ Enable TCP Routing

TCP Routing Ports (one-time configuration, if you want to update this value you can via the CF CLI) *

1024-1123

36. (Optional) To disable TCP routing, click **Select this option if you prefer to enable TCP Routing at a later time** For more information, see the [Configuring TCP Routing in PAS](#) topic.

37. Click **Save**

Step 5: Configure Application Containers

1. Select **Application Containers**.

Enable microservice frameworks, private Docker registries, and other services that support your applications at a container level.

- ☒ Enable Custom Buildpacks
- ☒ Allow SSH access to app containers
- ☒ Enable SSH when an app is created
- ☒ Enable the GrootFS container image plugin for Garden RunC
- ☐ Router uses TLS to verify application identity

Private Docker Insecure Registry Whitelist

10.10.10.10:8888,example.com:8888

Docker Images Disk-Cleanup Scheduling on Cell VMs*

- ☐ Never clean up Cell disk-space
- ☐ Routinely clean up Cell disk-space
- ☒ Clean up disk-space once threshold is reached

Threshold of Disk-Used (MB) (min: 1) *

10240

- The **Enable Custom Buildpacks** checkbox governs the ability to pass a custom buildpack URL to the `-b` option of the `cf push` command. By default, this ability is enabled, letting developers use custom buildpacks when deploying apps. Disable this option by disabling the checkbox. For more information about custom buildpacks, refer to the [buildpacks](#) section of the PCF documentation.
- The **Allow SSH access to app containers** checkbox controls SSH access to application instances. Enable the checkbox to permit SSH access across your deployment, and disable it to prevent all SSH access. See the [Application SSH Overview](#) topic for information about SSH access permissions at the space and app scope.
- If you want to enable SSH access for new apps by default in spaces that allow SSH, select **Enable SSH when an app is created**. If you deselect the checkbox, developers can still enable SSH after pushing their apps by running `cf enable-ssh APP-NAME`.
- If you want to disable the Garden Root filesystem (GrootFS), deselect the **Enable the GrootFS container image plugin for Garden RunC** checkbox. Pivotal recommends using this plugin, so it is enabled by default. However, some external components are sensitive to dependencies with filesystems such as GrootFS. If you experience issues, such as antivirus or firewall compatibility problems, deselect the checkbox to roll back to the plugin that is built into Garden RunC. For more information about GrootFS, see [Component: Garden](#) and [Container Mechanics](#).

 **Note:** If you modify this setting, Pivotal recommends recreating all VMs in the BOSH Director config. You can do this by selecting the **Recreate all VMs** checkbox in the **Director Config** pane of the BOSH Director tile before you redeploy.

- To enable Gorouter to verify app identity using TLS, select the **Router uses TLS to verify application identity** checkbox.

Verifying app identity using TLS enables encryption between router and app containers and guards against misrouting during control plane failures. For more information about Gorouter route consistency modes, see [Preventing Misrouting](#) in *HTTP Routing*.

 **warning:** TLS routing requires an additional 32 MB of RAM capacity on Diego cells per app instance. It also requires additional CPU capacity on Diego cells. If the total amount of Diego cell memory available is less than 32 MB times the number of running app instances, scale your Diego cells before configuring the Gorouter with TLS.

 **Warning:** You may see an increase of memory and CPU usage for your Gorouters after enabling TLS routing. If the total amount of memory and CPU usage of the Gorouters in your environment are close to the size limit, scale your Gorouters before enabling TLS routing.

7. You can configure Pivotal Application Service (PAS) to run app instances in Docker containers by supplying their IP address ranges in the **Private Docker Insecure Registry Whitelist** textbox. See the [Using Docker Registries](#) topic for more information.
8. Select your preference for **Docker Images Disk-Cleanup Scheduling on Cell VMs**. If you choose **Clean up disk-space once threshold is reached**, enter a **Threshold of Disk-Used** in megabytes. For more information about the configuration options and how to configure a threshold, see [Configuring Docker Images Disk-Cleanup Scheduling](#).
9. Enter a number in the **Max Inflight Container Starts** textbox. This number configures the maximum number of started instances across the Diego cells in your deployment. For more information about this feature, see [Setting a Maximum Number of Started Containers](#).
10. Under **Enabling NFSv3 volume services**, select **Enable** or **Disable**. NFS volume services allow application developers to bind existing NFS volumes to their applications for shared file access. For more information, see the [Enabling NFS Volume Services](#) topic.

 **Note:** In a clean install, NFSv3 volume services is enabled by default. In an upgrade, NFSv3 volume services is set to the same setting as it was in the previous deployment.

11. (Optional) To configure LDAP for NFSv3 volume services, do the following:

Enabling NFSv3 volume services will allow application developers to bind existing NFS volumes to their applications for shared file access. *

☒ Enable

LDAP Service Account User

LDAP Service Account Password

LDAP Server Host

LDAP Server Port

LDAP User Fully-Qualified Domain Name

☐ Disable

Format of timestamps in Diego logs*

☒ RFC3339 timestamps (e.g. 2018-02-09T00:54:13.479724884Z)

☐ Seconds since the Unix epoch (e.g. 1518137653.479724884)

Save

- For **LDAP Service Account User**, enter the username of the service account in LDAP that will manage volume services.
- For **LDAP Service Account Password**, enter the password for the service account.
- For **LDAP Server Host**, enter the hostname or IP address of the LDAP server.
- For **LDAP Server Port**, enter the LDAP server port number. If you do not specify a port number, Ops Manager uses 389.
- For **LDAP User Fully-Qualified Domain Name**, enter the fully qualified path to the LDAP service account. For example, if you have a service account named `volume-services` that belongs to organizational units (OU) named `service-accounts` and `my-company`, and your domain is named `domain`, the fully qualified path looks like the following:

```
CN=volume-services,OU=service-accounts,OU=my-company,DC=domain,DC=com
```

12. By default, PAS manages container images using the [GrootFS](#) plugin for Garden-runC. If you experience issues with GrootFS, you can disable the plugin and use the image plugin built into Garden-runC.

13. Select the **Format of timestamps in Diego logs**, either **RFC3339 timestamps** or **Seconds since the Unix epoch**. Fresh PAS v2.2 installations default to **RFC3339 timestamps**, while upgrades to PAS v2.2 from previous versions default to **Seconds since the Unix epoch**.
14. You can optionally modify the **Default health check timeout**. The value configured for this field is the amount of time allowed to elapse between starting up an app and the first healthy response from the app. If the health check does not receive a healthy response within the configured timeout, then the app is declared unhealthy. The default timeout is `60` seconds and the maximum configurable timeout is `600` seconds.
15. Click **Save**.

Step 6: Configure Application Developer Controls

1. Select **Application Developer Controls**.

Configure restrictions and default settings for applications pushed to Application Service.

Maximum File Upload Size (MB) (min: 1024, max: 2048) *

Default App Memory (MB) (min: 64, max: 2048) *

Default App Memory Quota per Org (MB) (min: 10240, max: 102400) *

Maximum Disk Quota per App (MB) (min: 512, max: 20480) *

Default Disk Quota per App (MB) (min: 512, max: 20480) *

Default Service Instances Quota per Org (min: 0, max: 1000) *

Staging Timeout (Seconds) *

☐ Allow Space Developers to manage network policies

☒ Enable Service Discovery for Apps

Save

2. Enter the **Maximum File Upload Size (MB)**. This is the maximum size of an application upload.
3. Enter the **Default App Memory (MB)**. This is the amount of RAM allocated by default to a newly pushed application if no value is specified with the cf CLI.
4. Enter the **Default App Memory Quota per Org**. This is the default memory limit for all applications in an org. The specified limit only applies to the first installation of PAS. After the initial installation, operators can use the cf CLI to change the default value.
5. Enter the **Maximum Disk Quota per App (MB)**. This is the maximum amount of disk allowed per application.

 **Note:** If you allow developers to push large applications, PAS may have trouble placing them on Cells. Additionally, in the event of a system

upgrade or an outage that causes a rolling deploy, larger applications may not successfully re-deploy if there is insufficient disk capacity. Monitor your deployment to ensure your Cells have sufficient disk to run your applications.

6. Enter the **Default Disk Quota per App (MB)**. This is the amount of disk allocated by default to a newly pushed application if no value is specified with the cf CLI.
7. Enter the **Default Service Instances Quota per Org**. The specified limit only applies to the first installation of PAS. After the initial installation, operators can use the cf CLI to change the default value .
8. Enter the **Staging Timeout (Seconds)**. When you stage an application droplet with the Cloud Controller, the server times out after the number of seconds you specify in this field.
9. Select the **Allow Space Developers to manage network policies** checkbox to permit developers to manage their own network policies for their applications.
10. The **Enable Service Discovery for Apps** checkbox, which enables service discovery between applications, is enabled by default. To disable this feature, clear this checkbox. For more information about application service discovery, see the [App Service Discovery](#) section of the *Understanding Container-to-Container Networking* topic.
11. Click **Save**.

Step 7: Review Application Security Groups

Setting appropriate [Application Security Groups](#) is critical for a secure deployment. Type in the box to acknowledge that once the Pivotal Application Service (PAS) deployment completes, you will review and set the appropriate application security groups. See [Restricting App Access to Internal PCF Components](#) for instructions.

Setting appropriate Application Security Groups that control application network policy is the responsibility of the Elastic Runtime administration team. Please refer to the Application Security Groups topic in the Pivotal Cloud Foundry documentation for more detail on completing this activity after the Elastic Runtime deployment completes.

Type X to acknowledge that you understand this message *

Save

Step 8: Configure Authentication and Enterprise SSO

1. Select **Authentication and Enterprise SSO**.

Configure your user store access, which can be an internal user store (managed by Cloud Foundry's UAA) or an external user store (LDAP or SAML). You can also adjust the lifetimes of authentication tokens.

Configure your UAA user account store with either internal or external authentication mechanisms *

☒ Internal UAA (provided by Elastic Runtime; configure your password policy below)

Minimum Password Length *

Minimum Uppercase Characters Required for Password *

Minimum Lowercase Characters Required for Password *

Minimum Numerical Digits Required for Password *

Minimum Special Characters Required for Password *

Maximum Password Entry Attempts Allowed *

2. To authenticate user sign-ons, your deployment can use one of three types of user database: the UAA server's internal user store, an external SAML identity provider, or an external LDAP server.

- To use the internal UAA, select the **Internal** option and follow the instructions in the [Configuring UAA Password Policy](#) topic to configure your password policy.
- To connect to an external identity provider through SAML, scroll down to select the **SAML Identity Provider** option and follow the instructions in the [Configuring PCF for SAML](#) section of the *Configuring Authentication and Enterprise SSO for Pivotal Application Service (PAS)* topic.
- To connect to an external LDAP server, scroll down to select the **LDAP Server** option and follow the instructions in the [Configuring LDAP](#) section of the *Configuring Authentication and Enterprise SSO for PAS* topic.

3. Click **Save**.

Step 9: Configure UAA

1. Select **UAA**.
2. (Optional) Under **JWT Issuer URI**, enter the URI that UAA uses as the issuer when generating tokens.

JWT Issuer URI

3. Under **SAML Service Provider Credentials**, enter a certificate and private key to be used by UAA as a SAML Service Provider for signing outgoing SAML authentication requests. You can provide an existing certificate and private key from your trusted Certificate Authority or generate a self-signed certificate. The following domain must be associated with the certificate: `*.login.YOUR-SYSTEM-DOMAIN`.

 **Note:** The Pivotal Single Sign-On Service and Pivotal Spring Cloud Services tiles require the `*.login.YOUR-SYSTEM-DOMAIN`.

4. If the private key specified under **Service Provider Credentials** is password-protected, enter the password under **SAML Service Provider Key**

SAML Service Provider Credentials *

-----BEGIN CERTIFICATE-----
M
U
H
M
-----END CERTIFICATE-----

[Change](#)

SAML Service Provider Key Password

Password.

- (Optional) To override the default value, enter a custom SAML Entity ID in the **SAML Entity ID Override** field. By default, the SAML Entity ID is `http://login.YOUR-SYSTEM-DOMAIN` where `YOUR-SYSTEM-DOMAIN` is set in the **Domains > System Domain** field.
- For **Signature Algorithm**, choose an algorithm from the dropdown menu to use for signed requests and assertions. The default value is `SHA256`.
- (Optional) In the **Apps Manager Access Token Lifetime**, **Apps Manager Refresh Token Lifetime**, **Cloud Foundry CLI Access Token Lifetime**, and **Cloud Foundry CLI Refresh Token Lifetime** fields, change the lifetimes of tokens granted for Apps Manager and Cloud Foundry Command Line Interface (cf CLI) login access and refresh. Most deployments use the defaults.

Apps Manager Access Token Lifetime (in seconds) *

1209600

Apps Manager Refresh Token Lifetime (in seconds) *

1209600

Cloud Foundry CLI Access Token Lifetime (in seconds) *

7200

Email

Customize Password Label (on login page) *

Password

Proxy IPs Regular Expression *

10\.\d{1,3}\.\d{1,3}\.\d{1,3}|192\.\d{1,3}\.\d{1,3}

[Save](#)

- (Optional) In the **Global Login Session Max Timeout** and **Global Login Session Idle Timeout** fields, change the maximum number of seconds before a global login times out. These fields apply to the following:

- **Default zone sessions:** Sessions in Apps Manager, PCF Metrics, and other web UIs that use the UAA default zones
 - **Identity zone sessions:** Sessions in apps that use a UAA identity zone, such as a Single Sign-On service plan
9. (Optional) Customize the text prompts used for username and password from the cf CLI and Apps Manager login popup by entering values for **Customize Username Label (on login page)** and **Customize Password Label (on login page)**.
 10. (Optional) The **Proxy IPs Regular Expression** field contains a pipe-delimited set of regular expressions that UAA considers to be reverse proxy IP addresses. UAA respects the `x-forwarded-for` and `x-forwarded-proto` headers coming from IP addresses that match these regular expressions. To configure UAA to respond properly to Gorouter or HAProxy requests coming from a public IP address, append a regular expression or regular expressions to match the public IP address.
 11. You can configure UAA to use an internal MySQL database provided with PCF, or you can configure an external database provider. Follow the procedures in either the [Internal Database Configuration](#) or the [External Database Configuration](#) section below.

 **Note:** If you are performing an upgrade, do not modify your existing internal database configuration or you may lose data. You must migrate your existing data before changing the configuration. See [Upgrading Pivotal Cloud Foundry](#) for additional upgrade information, and contact [Pivotal Support](#) for help.

Internal Database Configuration

When you configure the UAA to use an internal MySQL database, it uses the type of database selected in the **Databases** pane. See the [Configure Internal Databases](#) section for details.

1. Select **Internal MySQL**.

Choose the location of your UAA database *

☒ Internal MySQL (preferred for complete high-availability)

☐ External (preferred if, for example, you use AWS RDS)

 **Note:** If you configure your system databases as external in the **Databases** pane, selecting Internal MySQL in the **UAA** pane has no effect.

2. Click **Save**.
3. Ensure that you complete the [Configure Internal MySQL](#) step later in this topic to configure high availability for your internal MySQL databases.

External Database Configuration

1. From the **UAA** section in Pivotal Application Service (PAS), select **External**.

Choose the location of your UAA database *

☐ Internal MySQL (preferred for complete high-availability)

☒ External (preferred if, for example, you use AWS RDS)

Hostname *

TCP Port *

Username *

Password *

- For **Hostname**, enter the hostname of the database server.
- For **TCP Port**, enter the port of the database server.
- For **User Account and Authentication database username**, specify a unique username that can access this specific database on the database server.
- For **User Account and Authentication database password**, specify a password for the provided username.
- Click **Save**.

Step 10: Configure CredHub

 **Note:** Enabling CredHub is not required. However, you cannot leave the fields under **Encryption Keys** blank. If you do not intend to use CredHub, enter any text in the **Name** and **Key** fields as placeholder values.

- Select **CredHub**.
- Choose the location of your CredHub database. PAS includes this CredHub database for services to store their service instance credentials.

 **Note:** You cannot choose **Internal** for the CredHub database if you choose **External** for your System Databases. See [Configure System Databases](#) below.

Configure the CredHub Server

Choose the location of your CredHub database *

☒ Internal MySQL (preferred for complete high-availability)

☐ External (preferred if, for example, you use Google Cloud SQL)

If you chose **External**, enter the following:

- Hostname.** This is the IP address of your database server.
- TCP Port.** This is the port of your database server, such as `3306`.
- Username.** This is a unique username that can access your CredHub database on the database server.
- Password.** This is the password for the provided username.
- Database CA Certificate.** This certificate is used when encrypting traffic to and from the database.

- Under **Encryption Keys**, specify one or more keys to use for encrypting and decrypting the values stored in the CredHub database.

Encryption Keys

▼

Name *

Provider*

Internal

▲

▼

Key *

Secret

🔒

☐ Primary

Name of the encryption key.

- **Name.** This is the name of the encryption key.
 - If you plan to use internal encryption, enter any key name.
 - If you plan to use an HSM as your encryption provider, enter a key name that already exists on your HSM or a new key name. For each new key name, CredHub generates a key in **HSM Provider Partition** that you configure below.
- **Provider.** This is the provider of the encryption key. If you plan to configure an HSM provider and HSM servers below, select **HSM**. Otherwise, select **Internal**.
- **Key.** If you select internal encryption, this key is used for encrypting all data. The key must be at least 20 characters long.
 - If you selected **Internal** above, enter a randomly generated value under **Key**.
 - If you selected **HSM** above, enter a placeholder value under **Key**. CredHub does not use this key for encryption. However, you cannot leave the **Key** field blank.
- **Primary.** This checkbox is used for marking the key you specified above as the primary encryption key. You must mark one key as **Primary**. Do not mark more than one key as **Primary**.

 **Note:** For information about using additional keys for key rotation, see the [Rotating Runtime CredHub Encryption Keys](#) topic.

4. (Optional) To configure CredHub to use an HSM, complete the following fields:

- **HSM Provider Partition.** This is the name of the HSM provider partition.
- **HSM Provider Partition Password.** This password is used to access the HSM provider partition.
- **HSM Provider Client Certificate.** This is the client certificate for the HSM. For more information, see [Create and Register HSM Clients](#) [↗](#) in the

HSM Provider Partition

HSM Provider Partition Password

Secret

HSM Provider Client Certificate

Certificate PEM

Private Key PEM

Generate RSA Certificate

Preparing CredHub HSMs for Configuration topic.

- In the **HSM Provider Servers** section, click **Add** to add an HSM server. You can add multiple HSM servers. For each HSM server, complete the following fields:
 - **Host Address.** This is the host name or IP address of the HSM server.
 - **Port.** This is the port of the HSM server. If you do not know your port address, enter `1792`.
 - **Partition Serial Number.** This is the serial number of the HSM partition.
 - **HSM Certificate.** This is the certificate for the HSM server. The HSM presents this certificate to CredHub to establish a two-way TLS connection.

- If your deployment uses any PCF services that support storing service instance credentials in CredHub and you want to enable this feature, select the **Secure Service Instance Credentials** checkbox.
- Click **Save**.
- Select the **Resource Config** pane.
- Under the **Job** column of the **CredHub** row, set the number of instances to `2`. This is the minimum instance count required for high availability.
- Click **Save**.

For more information about using CredHub for securing service instance credentials, see [Securing Service Instance Credentials with Runtime CredHub](#).

Step 11: Configure System Databases You can configure PAS to use an internal MySQL database provided with PCF, or you can configure an external database provider for the databases required by PAS.

 **Note:** If you are performing an upgrade, do not modify your existing internal database configuration or you may lose data. You must migrate your existing data first before changing the configuration. See [Upgrading Pivotal Cloud Foundry](#) for additional upgrade information.

Internal Database Configuration

If you want to use internal databases for your deployment, perform the following steps:

- Select **Databases**.
- Select one of the **Internal Databases** options:
 - **Internal Databases - MySQL - Percona XtraDB Cluster** uses [Percona Server](#) with TLS encryption between server cluster nodes.
 - **Internal Databases - MySQL - MariaDB Galera Cluster** uses [MariaDB](#) with cluster nodes communicating over plaintext.

 **warning:** Changing existing internal databases from **MySQL - MariaDB Galera Cluster** to **MySQL - Percona XtraDB Cluster** migrates the databases after you click **Apply Changes**, causing temporary system downtime. See [Migrate to Internal Percona MySQL](#) for details.

Choose the location of your system databases. Please consult the documentation for migrating existing installations from MariaDB to Percona. *

- ☒ Internal Databases - MySQL - Percona XtraDB Cluster
- ☐ Internal Databases - MySQL - MariaDB Galera Cluster (deprecated - planned to be removed in PAS 2.4)
- ☐ External Databases - (e.g. AWS RDS)

Save

3. Click **Save**.

Then proceed to [Step 12: (Optional) Configure Internal MySQL](#internal-mysql) to configure high availability for your internal MySQL databases. ###
Create External System Databases

⚠ warning: Protect whichever database you use in your deployment with a password.

To create your Pivotal Application Service (PAS) databases, follow the procedure below.

💡 Note: Exact configurations depend on your database provider. The following procedure uses AWS RDS as an example.

1. Add the `ubuntu` account key pair from your IaaS deployment to your local SSH profile so you can access the Ops Manager VM. For example, in AWS, you add a key pair created in AWS:

```
$ ssh-add aws-keypair.pem
```

2. SSH in to your Ops Manager using the Ops Manager FQDN and the username `ubuntu`:

```
$ ssh ubuntu@OPS-MANAGER-FQDN
```

3. Log in to your MySQL database instance using the appropriate hostname and user login values configured in your IaaS account. For example, to log in to your AWS RDS instance, run the following MySQL command:

```
$ mysql --host=RDSHOSTNAME --user=RDSUSERNAME --password=RDSPASSWORD
```

4. Run the following MySQL commands to create databases for the PAS components that require a relational database:

```
CREATE database cedb;
CREATE database notifications;
CREATE database autoscale;
CREATE database app_usage_service;
CREATE database routing;
CREATE database diego;
CREATE database account;
CREATE database nfsvolume;
CREATE database networkpolicyserver;
CREATE database silk;
CREATE database locket;
CREATE database uaa;
CREATE database credhub;
```

💡 Note: The command `CREATE database credhub;` is optional if you have no CredHub instances. By default, CredHub has `0` instances.

5. Type `exit` to quit the MySQL client, and `exit` again to close your connection to the Ops Manager VM.

6. In PAS, select **Databases**.

7. Select the **External Databases** option.

💡 Note: If you configure databases as external, you cannot configure an internal database in the **UAA** pane.

8. For **Hostname**, enter the hostname of the database server.

9. For **TCP Port**, enter the port of the database server.
10. Each component that requires a relational database has two corresponding fields: one for the database username and one for the database password. For each set of fields, specify a unique username that can access this specific database on the database server and a password for the provided username.

 **Note:** Ensure that the networkpolicyserver database user has the `ALL PRIVILEGES` permission.

11. Click **Save**.

Step 12: (Optional) Configure Internal MySQL

 **Note:** You only need to configure this section if you have selected one of the **Internal Databases - MySQL** options in the **Databases** section.

To use internal MySQL in High Availability configuration, you define a load balancer rule that lets PAS components send queries a single hostname backed by two redundant proxies. Each proxy then directs query traffic to three MySQL server nodes.

1. Allocate an internal load balancer rule to balance traffic between two static IP addresses. The static IP addresses cannot be within the range that that you have reserved for PAS.
The load balancer rule is separate from the software provided by Pivotal, and you need to define it within your infrastructure.
 - **Make your idle time out long enough to not interrupt long-running queries.** When queries take a long time, the load balancer can time out and interrupt the query.
For example, [AWS's Elastic Load Balancer](#) has a default idle timeout of 60 seconds, so queries that take longer than this duration sever the MySQL connection and return an error.
 - **Configure a healthcheck or monitor, using TCP against port 1936.** This defaults to TCP port `1936`, to maintain backwards compatibility with previous releases. This port is not configurable. Unauthenticated healthchecks against port 3306 may cause the service to become unavailable and require manual intervention to fix.
 - **Configure the load balancer to route traffic for TCP port 3306 to the IPs of all proxy instances on TCP port 3306.**
 - Record the hostname of the load balancer rule and the two static IP addresses.

 **warning:** You must configure a load balancer to achieve complete high availability.

2. From the PAS tile in Ops Manager, Select **Internal MySQL**.
3. In the **MySQL Proxy IPs** field, enter the static IP addresses used by the internal MySQL load balancer rule.

Only configure this section if you selected Internal Databases - MySQL in the previous Databases section.

A proxy tier routes MySQL connections from internal components to healthy cluster nodes. Configure DNS and/or your own load balancer to point to multiple proxy instances for increased availability. TCP healthchecks can be configured against port 1936.

The automated backups functionality works with any S3-compatible file store that can receive your backup files.

MySQL Proxy IPs

MySQL Service Hostname

4. For **MySQL Service Hostname**, enter the IP address or hostname for your load balancer. If you leave this field blank, components are configured with the IP address of the first proxy instance entered above.
5. In the **Replication canary time period** field, leave the default of 30 seconds or modify the value based on the needs of your deployment. Lower numbers cause the canary to run more frequently, which means that the canary reacts more quickly to replication failure but adds load to the database.
6. In the **Replication canary read delay** field, leave the default of 20 seconds or modify the value based on the needs of your deployment. This field configures how long the canary waits, in seconds, before verifying that data is replicating across each MySQL node. Clusters under heavy load can experience a small replication lag as write-sets are committed across the nodes.

7. (**Required**): In the **E-mail address** field, enter the email address where the MySQL service sends alerts when the cluster experiences a replication issue or when a node is not allowed to auto-rejoin the cluster.
8. To prohibit the creation of command line history files on the MySQL nodes, disable the **Allow Command History** checkbox.
9. To allow the admin and roadmin to connect from any remote host, enable the **Allow Remote Admin Access** checkbox. When the checkbox is disabled, admins must `bosh ssh` into each MySQL VM to connect as the MySQL super user.

 **Note:** Network configuration and Application Security Groups restrictions may still limit a client's ability to establish a connection with the databases.

10. For **Cluster Probe Timeout**, enter the maximum amount of time, in seconds, that a new node will search for existing cluster nodes. If left blank, the default value is 10 seconds.

Replication canary time period *

Replication canary read delay *

E-mail address (required) *

☒ Allow Command History

Cluster Probe Timeout

11. For **Max Connections**, enter the maximum number of connections allowed to the database. If left blank, the default value is 1500.
12. If you want to log audit events for internal MySQL, select **Enable server activity logging** under **Server Activity Logging**.
 - a. For the **Event types** field, you can enter the events you want the MySQL service to log. By default, this field includes `connect` and `query`, which tracks who connects to the system and what queries are processed.

Server Activity Logging *

☐ Disable server activity logging
☒ Enable server activity logging

Event types *

Load Balancer Healthy Threshold *

Load Balancer Unhealthy Threshold *

13. Enter values for the following fields:

- **Load Balancer Healthy Threshold:** Specifies the amount of time, in seconds, to wait until declaring the MySQL Proxy instance started. This allows an external load balancer time to register the instance as healthy.
- **Load Balancer Unhealthy Threshold:** Specifies the amount of time, in seconds, that the MySQL Proxy continues to accept connections before shutting down. During this period, the Healthcheck reports as unhealthy to cause load balancers to fail over to other proxies. You must enter a value greater than or equal to the maximum time it takes your load balancer to consider a proxy instance unhealthy, given repeated failed healthchecks.

14. If you want to enable the MySQL interruptor feature, select the checkbox to **Prevent node auto re-join**. This feature stops all writes to the MySQL database if it notices an inconsistency in the dataset between the nodes. For more information, see the [Interruptor](#) section in the MySQL for PCF documentation.

15. Click **Save**.

For more information on how to monitor the node health of your MySQL Proxy instances, see [Using the MySQL Proxy](#).

Step 13: Configure File Storage

 **Note:** If you followed the instructions in [Installing PCF on AWS Manually](#), you created the necessary resources for [external S3-compatible file storage](#).

To minimize system downtime, Pivotal recommends using highly resilient and redundant *external* filestores for your Pivotal Application Service (PAS) file storage.

When configuring file storage for the Cloud Controller in PAS, you can select one of the following:

- Internal WebDAV filestore
- External S3-compatible or Ceph-compatible filestore
- External Google Cloud Storage with Access Key and Secret Key
- External Google Cloud Storage with Service Account
- External Azure Cloud Storage

For production-level PCF deployments on AWS, Pivotal recommends selecting the **External S3-Compatible File Store**. For more information about production-level PCF deployments on AWS, see the [Reference Architecture for Pivotal Cloud Foundry on AWS](#).

For more factors to consider when selecting file storage, see the [Considerations for Selecting File Storage in Pivotal Cloud Foundry](#) topic.

Internal Filestore

Internal file storage is only appropriate for small, non-production deployments.

To use the PCF internal filestore, perform the following steps:

1. In the Pivotal Application Service (PAS) tile, select **File Storage**.
2. Select **Internal WebDAV**, and click **Save**.

External S3 or Ceph Filestore

To use an external S3-compatible filestore for PAS file storage, perform the following steps:

1. In the PAS tile, select **File Storage**.
2. Select the **External S3-Compatible Filestore** option and complete the following fields:
 - Enter the `https://` **URL Endpoint** for your region.
For example, in the **us-west-2** region, enter `https://s3-us-west-2.amazonaws.com/`.
 - If you use an AWS instance profile to manage role information for your filestore, select the **S3 AWS with Instance Profile** checkbox. For more information, see [AWS Identity and Access Management](#) in the AWS documentation.

☒ S3 AWS with Instance Profile

Access Key (required if not using S3 AWS with Instance Profile)

Secret Key (required if not using S3 AWS with Instance Profile)

- Alternatively, enter the **Access Key** and **Secret Key** of the `pcf-user` you created when configuring AWS for PCF. If you select the **S3 AWS with Instance Profile** checkbox and also enter an **Access Key** and **Secret Key**, the instance profile will overrule the Access Key and Secret Key.
- From the **S3 Signature Version** dropdown, select **V4 Signature**. For more information about S4 signatures, see [Signing AWS API Requests](#) in the AWS documentation.
- For **Region**, enter the region in which your S3 buckets are located. `us-west-2` is an example of an acceptable value for this field.
- Select **Server-side Encryption** to encrypt the contents of your S3 filestore. This option is only available for AWS S3.
- (Optional) If you selected **Server-side Encryption**, you can also specify a **KMS Key ID**. PAS uses the KMS key to encrypt files uploaded to the blobstore. If you do not provide a KMS Key ID, PAS uses the default AWS key. For more information, see [Protecting Data Using Server-Side Encryption with AWS KMS-Managed Keys \(SSE-KMS\)](#).
- Enter names for your S3 buckets:

| Ops Manager Field | Value | Description |
|------------------------|-----------------------|---|
| Buildpacks Bucket Name | pcf-buildpacks-bucket | This S3 bucket stores app buildpacks. |
| Droplets Bucket Name | pcf-droplets-bucket | This S3 bucket stores app droplets. Pivotal recommends that you use a unique bucket name for droplets, but you can also use the same name as above. |
| Packages Bucket Name | pcf-packages-bucket | This S3 bucket stores app packages. Pivotal recommends that you use a unique bucket name for packages, but you can also use the same name as above. |
| Resources Bucket Name | pcf-resources-bucket | This S3 bucket stores app resources. Pivotal recommends that you use a unique bucket name for app resources, but you can also use the same name as above. |

- Configure the following depending on whether your S3 buckets have versioning enabled:
 - Versioned S3 buckets:** Enable the **Use versioning for backup and restore** checkbox to archive each bucket to a version.
 - Unversioned S3 buckets:** Disable the **Use versioning for backup and restore** checkbox, and enter a backup bucket name for each active bucket. The backup bucket name must be different from the name of the active bucket it backs up.

☐ Use versioning for backup and restore.
 (All of the above buckets must have versioning enabled and use the V4 S3 Signature Version).

If versioning is not enabled or supported, you can configure separate buckets below for backups. More information at <https://docs.pivotal.io/pivotalcf/2-1/customizing/backup-restore/backup-pcf-bbr.html>.

Backup Region

Backup Buildpacks Bucket Name

Backup Droplets Bucket Name

Backup Packages Bucket Name

For more information about setting up external S3 blobstores, see the [Backup and Restore with External Blobstores](#) topic in the Cloud Foundry documentation.

3. Click **Save**.

 **Note:** For more information regarding AWS S3 Signatures, see the [Authenticating Requests](#)  topic in the AWS documentation.

Other IaaS Storage Options

[Google Cloud Storage](#) and [Azure Storage](#) are also available as file storage options, but are not recommended for typical PCF on AWS installations.

Step 14: (Optional) Configure System Logging

You can configure system logging in PAS to forward log messages from PAS component VMs to an external service. Pivotal recommends forwarding logs to an external service for use in troubleshooting.

 **Note:** The following instructions explain how to configure system logging for PAS component VMs. To forward logs from PCF tiles to an external service, you must also configure system logging in each tile. See the documentation for the given tiles for information about configuring system logging.

To configure system logging in PAS, do the following:

1. In the PAS **Settings** tab, select the **System Logging** pane. The following image shows the **System Logging** pane.

Optionally configure rsyslog to forward platform component logs to an external service. If you do not fill these fields, platform logs will not be forwarded but will remain available on the component VMs and for download via Ops Manager.

Address

Port

Transport Protocol

Encrypt syslog using TLS?*

- ☒ No
☐ Yes

Syslog Drain Buffer Size (# of messages) *

☒ Include container metrics in SysLog Drains

☒ Enable Cloud Controller security event logging

☐ Use TCP for file forwarding local transport

☒ Don't Forward Debug Logs

Custom rsyslog Configuration

Save

2. For **Address**, enter the IP address of the syslog server.
3. For **Port**, enter the port of the syslog server. The default port for a syslog server is `514`.

 **Note:** The host must be reachable from the PAS network and accept UDP or TCP connections. Ensure the syslog server listens on external interfaces.

4. For **Transport Protocol**, select a transport protocol for log forwarding.
5. For **Encrypt syslog using TLS?**, select **Yes** to use TLS encryption when forwarding logs to a remote server.
 - a. For **Permitted Peer**, enter either the name or SHA1 fingerprint of the remote peer.
 - b. For **TLS CA Certificate**, enter the TLS CA certificate for the remote server.
6. For **Syslog Drain Buffer Size**, enter the number of messages from the Loggregator Agent that the Doppler server can store before it begins to drop messages. See the [Loggregator Guide for Cloud Foundry Operators](#) topic for more details.
7. Disable the **Include container metrics in Syslog Drains** checkbox to prevent the [CF Drain CLI plugin](#) from including app container metrics in syslog drains. This feature is enabled by default.

8. Enable the **Enable Cloud Controller security event logging** checkbox to include security events in the log stream. This feature logs all API requests, including the endpoint, user, source IP address, and request result, in the Common Event Format (CEF).
9. Enable the **Use TCP for file forwarding local transport** checkbox to transmit logs over TCP. This prevents log truncation, but may cause performance issues.
10. Disable the **Don't Forward Debug Logs** checkbox to forward DEBUG syslog messages to an external service. This checkbox is enabled by default.

 **Note:** Some PAS components generate a high volume of DEBUG syslog messages. Enabling the **Don't Forward Debug Logs** checkbox prevents PAS components from forwarding the DEBUG syslog messages to external services. However, PAS still writes the messages to the local disk.

11. For **Custom rsyslog Configuration**, enter a custom syslog rule. For more information about adding custom syslog rules, see [Customizing Syslog Rules](#).
12. Click **Save**.

To configure Ops Manager for system logging, see the [Settings](#) section in the *Using the Ops Manager Interface* topic.

Step 15: (Optional) Customize Apps

This section describes how to configure **Custom Branding** and **Apps Manager** to customize the appearance and functionality of Apps Manager. For more information about the **Custom Branding** configuration settings, see [Custom Branding Apps Manager](#).

1. Select **Custom Branding**. Use this section to configure the text, colors, and images of the interface that developers see when they log in, create an account, reset their password, or use Apps Manager.

Customize colors, images, and text for Apps Manager and the Cloud Foundry login portal.

Company Name

Accent Color

Main Logo (PNGs only)

Square Logo/Favicon (PNGs only)

Footer Text

Defaults to 'Pivotal Software Inc. All rights reserved.'

Footer Links

You may configure up to three links in the Apps Manager footer

Classification Header/Footer Background Color

Classification Header/Footer Text Color

Classification Header Content

Classification Footer Content

Save

2. Click **Save** to save your settings in this section.
3. Select **Apps Manager**.

Configure Apps Manager

☒ Enable Invitations

☐ Display Marketplace Service Plan Prices

Supported currencies as JSON *

```
{ "usd": "$", "eur": "€" }
```

Product Name

Marketplace Name

Customize Sidebar Links Add

You may configure up to 10 links in the Apps Manager sidebar.

- ▶ Marketplace 🗑️
- ▶ Docs 🗑️
- ▶ Tools 🗑️

Apps Manager Memory Usage (MB) (min: 128)

Invitations Memory Usage (MB) (min: 256)

Apps Manager Polling Interval *

30

Apps manager polling interval in seconds. As a workaround to reduce load on the Cloud Controller API, increase the polling interval or set to 0 to stop polling. Values between 0 and 30 will default to 30 seconds.

Save

- Select **Enable Invitations** to enable invitations in Apps Manager. Space Managers can invite new users for a given space, Org Managers can invite new users for a given org, and Admins can invite new users across all orgs and spaces. See the [Inviting New Users](#) section of the *Managing User Roles with Apps Manager* topic for more information.
- Select **Display Marketplace Service Plan Prices** to display the prices for your services plans in the Marketplace.
- Enter the **Supported currencies as JSON** to appear in the Marketplace. Use the format `{ "CURRENCY-CODE": "SYMBOL" }`. This defaults to `{ "usd": "$", "eur": "€" }`.
- Use **Product Name**, **Marketplace Name**, and **Customize Sidebar Links** to configure page names and sidebar links in the **Apps Manager** and **Marketplace** pages.
- The **Apps Manager Memory Usage (MB)** field sets the memory limit with which to deploy the Apps Manager app. Use this field to increase the memory limit if the app fails to start with an `out of memory` error.
- The **Invitations Memory Usage (MB)** field sets the memory limit with which to deploy the Invitations app. Use this field to increase the memory limit if the app fails to start with an `out of memory` error.

10. The **Apps Manager Polling Interval** field provides a temporary fix if Apps Manager usage degrades Cloud Controller response times. In this case, you can use this field to reduce the load on the Cloud Controller and ensure Apps Manager remains available while you troubleshoot the Cloud Controller. Pivotal recommends that you do not keep this field modified as a long term fix because it can degrade Apps Manager performance. You can optionally do the following:

- Increase the polling interval above the default of `30` seconds.

 **Note:** If you enter a value between `0` and `30`, the field is automatically set to `30`.

- Disable polling by entering `0`. This stops Apps Manager from refreshing data automatically, but users can update displayed data by reloading Apps Manager manually.

11. Click **Save** to save your settings in this section.

Step 16: (Optional) Configure Email Notifications

PAS uses SMTP to send invitations and confirmations to Apps Manager users. You must complete the **Email Notifications** page if you want to enable end-user self-registration.

1. Select **Email Notifications**.

Configure Simple Mail Transfer Protocol for the Notifications application to send email notifications about your deployment. This application is deployed as an errand in Elastic Runtime. If you do not need this service, leave this section blank and disable the Notifications and Notifications UI errands.

From Email

Address of SMTP Server

Port of SMTP Server

SMTP Server Credentials

[Change](#)

☒ SMTP Enable Automatic STARTTLS

SMTP Authentication Mechanism*

SMTP CRAMMD5 secret

Save

2. Enter your reply-to and SMTP email information.

 **Note:** For GCP, you must use port `2525`. Ports `25` and `587` are not allowed on GCP Compute Engine.

3. Verify your authentication requirements with your email administrator and use the **SMTP Authentication Mechanism** dropdown to select `None`, `Plain`, or `CRAMMD5`. If you have no SMTP authentication requirements, select `None`.

- If you selected `CRAMMD5` as your authentication mechanism, enter a secret in the **SMTP CRAMMD5 secret** field.
- Click **Save**.

Note: If you do not configure the SMTP settings using this form, the administrator must create orgs and users using the cf CLI. See [Creating and Managing Users with the cf CLI](#) for more information.

Step 17: (Optional) Configure App Autoscaler

To use App Autoscaler, you must create an instance of the service and bind it to an app. To create an instance of App Autoscaler and bind it to an app, see [Set Up App Autoscaler](#) in the *Scaling an Application Using App Autoscaler* topic.

- Click **App Autoscaler**.

Configure the App Autoscaler

Autoscaler Instance Count (min: 1) *

Autoscaler API Instance Count (min: 1) *

Metric Collection Interval (min: 60, max: 3600) (min: 60, max: 3600) *

Scaling Interval (min: 15, max: 120) (min: 15, max: 120) *

☐ Verbose Logging

☐ Disable API Connection Pooling

☒ Enable Notifications

Save

- Review the following settings:

- Autoscaler Instance Count:** How many instances of the App Autoscaler service you want to deploy. The default value is `3`. For high availability, set this number to `3` or higher. You should set the instance count to an odd number to avoid split-brain scenarios during leadership elections. Larger environments may require more instances than the default number.
- Autoscaler API Instance Count:** How many instances of the App Autoscaler API you want to deploy. The default value is `1`. Larger environments may require more instances than the default number.
- Metric Collection Interval:** How many seconds of data collection you want App Autoscaler to evaluate when making scaling decisions. The minimum interval is 60 seconds, and the maximum interval is 3600 seconds. The default value is `120`. Increase this number if the metrics you use in your scaling rules are emitted less frequently than the existing Metric Collection Interval.
- Scaling Interval:** How frequently App Autoscaler evaluates an app for scaling. The minimum interval is 15 seconds, and the maximum interval is 120 seconds. The default value is `35`.
- Verbose Logging** (checkbox): Enables verbose logging for App Autoscaler. Verbose logging is disabled by default. Select this checkbox to see more detailed logs. Verbose logs show specific reasons why App Autoscaler scaled the app, including information about minimum and maximum instance limits, App Autoscaler's status. For more information about App Autoscaler logs, see [App Autoscaler Events and Notifications](#).
- Disable API Connection Pooling:** API connection pooling increases performance by reducing the cost associated with establishing new connections. If you do not want to keep connections open for reuse, select this option.

3. Click **Save**.

Step 18: Configure Cloud Controller

1. Click **Cloud Controller**.

Configure the Cloud Controller

Cloud Controller DB Encryption Key

Secret

Enabling CF API Rate Limiting will prevent API consumers from overwhelming the platform API servers. Limits are imposed on a per-user or per-client basis and reset on an hourly interval. *

☐ Enable
 ☒ Disable

Save

2. Enter your **Cloud Controller DB Encryption Key** if all of the following are true:

- You deployed Pivotal Application Service (PAS) previously.
- You then stopped PAS or it crashed.
- You are re-deploying PAS with a backup of your Cloud Controller database.

See [Backing Up Pivotal Cloud Foundry](#) for more information.

3. CF API Rate Limiting prevents API consumers from overwhelming the platform API servers. Limits are imposed on a per-user or per-client basis and reset on an hourly interval.

To disable CF API Rate Limiting, select **Disable** under **Enable CF API Rate Limiting**. To enable CF API Rate Limiting, perform the following steps:

- Under **Enable CF API Rate Limiting**, select **Enable**.
- For **General Limit**, enter the number of requests a user or client is allowed to make over an hour interval for all endpoints that do not have a custom limit. The default value is `2000`.
- For **Unauthenticated Limit**, enter the number of requests an unauthenticated client is allowed to make over an hour interval. The default value is `100`.

4. Click **Save**.

Step 19: Configure Smoke Tests

The Smoke Tests errand runs basic functionality tests against your Pivotal Application Service (PAS) deployment after an installation or update. In this section, choose where to run smoke tests. In the **Errands** section, you can choose whether or not to run the Smoke Tests errand.

1. Select **Smoke Tests**.
2. If you have a shared apps domain, select **Temporary space within the system organization**, which creates a temporary space within the `system` organization for running smoke tests and deletes the space afterwards. Otherwise, select **Specified org and space** and complete the fields to specify where you want to run smoke tests.

Specify a Cloud Foundry organization and space where smoke tests can run if in the future you delete your Elastic Runtime deployment domains.

Choose where to deploy applications when running the smoke tests *

- ☐ Temporary space within the system organization (This is deleted after smoke tests finish.)
- ☒ Specified org and space (The org and space must have a domain available for routing.)

Organization *

Space *

Domain *

Save

3. Click **Save**.

Step 20: (Optional) Enable Advanced Features

The **Advanced Features** section of Pivotal Application Service (PAS) includes new functionality that may have certain constraints. Although these features are fully supported, Pivotal recommends caution when using them in production environments.

Diego Cell Memory and Disk Overcommit

If your apps do not use the full allocation of disk space and memory set in the **Resource Config** tab, you might want use this feature. These fields control the amount to overcommit disk and memory resources to each Diego Cell VM.

For example, you might want to use the overcommit if your apps use a small amount of disk and memory capacity compared to the amounts set in the **Resource Config** settings for **Diego Cell**.

Note: Due to the risk of app failure and the deployment-specific nature of disk and memory use, Pivotal has no recommendation about how much, if any, memory or disk space to overcommit.

To enable overcommit, do the following:

1. Select **Advanced Features**.

Cell Memory Capacity (MB) (min: 1)

Cell Disk Capacity (MB) (min: 1)

2. Enter the total desired amount of Diego cell memory value in the **Cell Memory Capacity (MB)** field. Refer to the **Diego Cell** row in the **Resource Config** tab for the current Cell memory capacity settings that this field overrides.
3. Enter the total desired amount of Diego cell disk capacity value in the **Cell Disk Capacity (MB)** field. Refer to the **Diego Cell** row in the **Resource Config** tab for the current Cell disk capacity settings that this field overrides.
4. Click **Save**.

 **Note:** Entries made to each of these two fields set the total amount of resources allocated, not the overage.

Whitelist for Non-RFC-1918 Private Networks

Some private networks require extra configuration so that internal file storage (WebDAV) can communicate with other PCF processes.

The **Whitelist for non-RFC-1918 Private Networks** field is provided for deployments that use a non-RFC 1918 private network. This is typically a private network other than `10.0.0.0/8`, `172.16.0.0/12`, or `192.168.0.0/16`.

Most PCF deployments do not require any modifications to this field.

To add your private network to the whitelist, do the following:

1. Select **Advanced Features**.
2. Append a new `allow` rule to the existing contents of the **Whitelist for non-RFC-1918 Private Networks** field.

Whitelist for non-RFC-1918 Private Networks *

allow 10.0.0.0/8;;allow 172.16.0.0/12;;allow .

If your Elastic Runtime deployment is using a private network that is not RFC 1918 (10.0.0.0/8, 172.16.0.0/12, 192.168.0.0/16), then you must type in "allow <your-network>;" here. It is important to include the word "allow" and the semi-colon at the end. For example, "allow 172.99.0.0/24;"

Include the word `allow`, the network CIDR range to allow, and a semi-colon (`;`) at the end. For example: `allow 172.99.0.0/24;`

3. Click **Save**.

CF CLI Connection Timeout

The **CF CLI Connection Timeout** field allows you to override the default five second timeout of the Cloud Foundry Command Line Interface (cf CLI) used within your PCF deployment. This timeout affects the cf CLI command used to push PAS errand apps such as Notifications, Autoscaler, and Apps Manager.

Set the value of this field to a higher value, in seconds, if you are experiencing domain name resolution timeouts when pushing errands in PAS.

To modify the value of the **CF CLI Connection Timeout**, perform the following steps:

1. Select **Advanced Features**.

CF CLI Connection Timeout

15

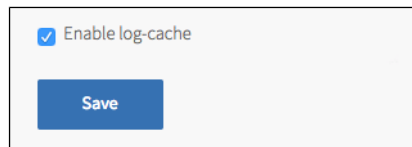

2. Add a value, in seconds, to the **CF CLI Connection Timeout** field.
3. Click **Save**.

Log Cache

Log Cache is an in-memory caching layer for logs and metrics. This Loggregator feature lets users filter and query logs through a CLI or API endpoints. Cached logs are available on demand. For more information about Log Cache, see [Enable Log Cache](#) in the *Configuring Logging in PASTopic*.

To configure the **Enable log-cache** checkbox, do the following:

1. Select **Advanced Features**.

2. Select or deselect the **Enable log-cache** checkbox.
3. Click **Save**.

Database Connection Limits

You can configure the maximum number of concurrent database connections that diego and container networking components can have. Use the field beginning with **Maximum number of open connections...** for a given component. The placeholder values for each field are the default values.

When there are not enough connections available, such as during a time of heavy load, components may experience degraded performance and sometimes failure. To resolve or prevent this, you can increase and fine-tune database connection limits for the component.

⚠ warning: Decreasing the value of this field for a component may affect the amount of time it takes for it to respond to requests.

Step 21: Configure Errands

Errands are scripts that Ops Manager runs automatically when it installs or uninstalls a product, such as a new version of Pivotal Application Service (PAS). There are two types of errands: *post-deploy errands* run after the product is installed, and *pre-delete errands* run before the product is uninstalled.

By default, Ops Manager always runs all errands.

The PAS tile **Errands** pane lets you change these run rules. For each errand, you can select **On** to run it always or **Off** to never run it.

For more information about how Ops Manager manages errands, see the [Managing Errands in Ops Manager](#) topic.

💡 Note: Several errands, such as App Autoscaler and Notifications, deploy apps that provide services for your deployment. When one of these apps is running, selecting **Off** for the corresponding errand on a subsequent installation does not stop the app.

- **Smoke Test Errand** verifies that your deployment can do the following:
 - Push, scale, and delete apps
 - Create and delete orgs and spaces
- **Usage Service Errand** deploys the Pivotal Usage Service application, which Apps Manager depends on.
- **Apps Manager Errand** deploys Apps Manager, a dashboard for managing apps, services, orgs, users, and spaces. Until you deploy Apps Manager, you must perform these functions through the cf CLI. After Apps Manager has been deployed, Pivotal recommends setting this errand to **Off** for subsequent PAS deployments. For more information about Apps Manager, see the [Getting Started with the Apps Manager](#) topic.
- **Notifications Errand** deploys an API for sending email notifications to your PCF platform users.

💡 Note: The Notifications app requires that you [configure SMTP](#) with a username and password, even if you set the value of **SMTP Authentication Mechanism** to `none`.

- **Notifications UI Errand** deploys a dashboard for users to manage notification subscriptions.
- **App Autoscaler Errand** enables you to configure your apps to automatically scale in response to changes in their usage load. See the [Scaling an Application Using Autoscaler](#) topic for more information.
- **NFS Broker Errand** enables you to use NFS Volume Services by installing the NFS Broker app in PAS. See the [Enabling NFS Volume Services](#) topic for more information.

Step 22: (Optional) Disable Unused Resources

💡 Note: The **Resource Config** pane has fewer VMs if you are installing the [Small Footprint Runtime](#).

 **Note:** The Small Footprint Runtime does not default to a highly available configuration. It defaults to the minimum configuration. If you want to make the Small Footprint Runtime highly available, scale the **Compute**, **Router**, and **Database** VMs to instances and scale the **Control** VM to instances.

Pivotal Application Service (PAS) defaults to a highly available resource configuration. However, you may need to perform additional procedures to make your deployment highly available. See the [Zero Downtime Deployment and Scaling in CF](#) and the [Scaling Instances in PAS](#) topics for more information.

If you do not want a highly available resource configuration, you must scale down your instances manually by navigating to the **Resource Config** section and using the dropdowns under **Instances** for each job.

By default, PAS also uses an internal filestore and internal databases. If you configure PAS to use external resources, you can disable the corresponding system-provided resources in Ops Manager to reduce costs and administrative overhead.

To disable specific VMs in Ops Manager, do the following:

1. Click **Resource Config**.
2. If you configured PAS to use an external S3-compatible filestore, enter in **Instances** in the **File Storage** field.
3. If you selected **External** when configuring the UAA, System, and CredHub databases, edit the following fields:
 - **MySQL Proxy:** Enter in **Instances**.
 - **MySQL Server:** Enter in **Instances**.
 - **MySQL Monitor:** Enter in **Instances**.
4. If you disabled TCP routing, enter **Instances** in the **TCP Router** field.
5. If you are not using HAProxy, enter **Instances** in the **HAProxy** field.
6. Click **Save**.

Step 23: Configure Router to Elastic Load Balancers

1. Record the names of your ELBs. If you followed the procedures in the [Installing PCF on AWS Manually](#) topic, you created the following:
 - `pcf-ssh-elb`: A SSH load balancer. This is a Classic Load Balancer.
 - `pcf-tcp-elb`: A TCP load balancer. This is a Classic Load Balancer.
 - `pcf-web-elb`: A web load balancer. This is an Application Load Balancer.
 - `pcf-web-elb-target-group`: a target group for the web load balancer
2. In the PAS tile, click **Resource Config**.

Resource Config

| JOB | INSTANCES | PERSISTENT DISK TYPE | VM TYPE | LOAD BALANCERS | INTERNET CONNECTED |
|-------------------------------|--------------|----------------------|---|----------------|-------------------------------------|
| Consul | 1 | Automatic: 1 GB | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| NATS | 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| File Storage | Automatic: 1 | Automatic: 100 GB | Automatic: medium.mem (cpu: 1, ram: 6 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| MySQL Proxy | 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| MySQL Server | 1 | Automatic: 100 GB | Automatic: large.disk (cpu: 2, ram: 8 GB, disk: 64 GB) | | <input checked="" type="checkbox"/> |
| Backup Prepare Node | Automatic: 1 | Automatic: 200 GB | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| Diego BBS | 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| UAA | 1 | None | Automatic: medium.disk (cpu: 2, ram: 4 GB, disk: 32 GB) | | <input checked="" type="checkbox"/> |
| Cloud Controller | 1 | None | Automatic: medium.disk (cpu: 2, ram: 4 GB, disk: 32 GB) | | <input checked="" type="checkbox"/> |
| HAProxy | Automatic: 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| Router | 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | pcf-web-elb | <input checked="" type="checkbox"/> |
| MySQL Monitor | Automatic: 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| Clock Global | Automatic: 1 | None | Automatic: medium.disk (cpu: 2, ram: 4 GB, disk: 32 GB) | | <input checked="" type="checkbox"/> |
| Cloud Controller Worker | 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| Diego Brain | 1 | Automatic: 1 GB | Automatic: small (cpu: 1, ram: 2 GB, disk: 8 GB) | pcf-ssh-elb | <input checked="" type="checkbox"/> |
| Diego Cell | 1 | None | Automatic: xlarge.disk (cpu: 4, ram: 16 GB, disk: 128 GB) | | <input checked="" type="checkbox"/> |
| Loggregator Trafficcontroller | 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| Syslog Adapter | 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| Syslog Scheduler | 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| Doppler Server | 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| TCP Router | 0 | Automatic: 1 GB | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | pcf-tcp-elb | <input checked="" type="checkbox"/> |
| CredHub | Automatic: 0 | None | Automatic: large (cpu: 2, ram: 8 GB, disk: 16 GB) | | <input checked="" type="checkbox"/> |

Save

3. Enter the name of your SSH load balancer depending on which release you are using.

- **PAS:** In the **Load Balancers** field of the **Diego Brain** row, enter the name of your SSH load balancer: `pcf-ssh-elb`.
- **Small Footprint Runtime:** In the **Load Balancers** field of the **Control** row, enter the name of your SSH load balancer: `pcf-ssh-elb`.

4. In the **Load Balancers** field of the **Router** row, enter the value determined by the type of load balancer you are using:

- **Application Load Balancer:** Enter the name of the target group of your web load balancer, prefixed with `alb:`: `alb:pcf-web-elb-target-group`. The prefix indicates to Ops Manager that you entered the name of a target group, and is required for AWS Application Load Balancers or Network Load Balancers.
- **Classic Load Balancer:** Enter the name of the load balancer: `pcf-web-elb`.

 **Note:** If you are using HAProxy in your deployment, then put the name of the load balancers in the **Load Balancers** field of the **HAProxy** row instead of the **Router** row. For a high availability configuration, scale up the HAProxy job to more than one instance.

5. In the **Load Balancers** field of the **TCP Router** row, enter the name of your TCP load balancer if you enabled TCP routing: `pcf-tcp-elb`.

Step 24: Download Stemcell

This step is only required if your Ops Manager does not already have the stemcell version required by PAS. For more information about importing stemcells, see [Importing and Managing Stemcells](#).

1. Open the [Stemcell product page](#) in the Pivotal Network. *Note, you may have to log in.*
2. Download the appropriate stemcell version targeted for your IaaS.
3. Navigate to **Stemcell Library** in the **Installation Dashboard**.
4. Click **Import Stemcell** to import the downloaded stemcell `.tgz` file.
5. When prompted, enable the Ops Manager product checkbox to stage your stemcell.

6. Click **Apply Stemcell to Products**.

Step 25: Complete the PAS Installation

1. Click the **Installation Dashboard** link to return to the Installation Dashboard.
2. Click **Apply Changes** to begin your installation of PAS.

The install process generally requires a minimum of 90 minutes to complete. The image shows the **Changes Applied** window that displays when the installation process successfully completes.

Installing PCF on AWS using Terraform

This topic explains how to install PCF on AWS using Terraform.

Overview

You can install PCF on AWS with either the Pivotal Application Service (PAS) or Pivotal Container Service (PKS) runtime.

To install PCF on AWS using Terraform, do one of the following:

- Install with PAS. See [Install with PAS Using Terraform](#).
- Install with PKS. See [Install with PKS Using Terraform](#).

Install with PAS Using Terraform

To install with PAS using Terraform, do the following:

1. Deploy Ops Manager. See [Deploying Ops Manager on AWS Using Terraform](#).
2. Configure BOSH Director. See [Configuring BOSH Director on AWS Using Terraform](#).
3. Configure PAS. See [Deploying PAS on AWS Using Terraform](#).

Install with PKS Using Terraform

To install with PKS using Terraform, do the following:

1. Deploy Ops Manager. See [Deploying Ops Manager on AWS Using Terraform](#).
2. Configure BOSH Director. See [Configuring BOSH Director on AWS Using Terraform](#).
3. Configure PKS. See [Installing PKS on AWS](#) ↗.

Deploying Ops Manager on AWS Using Terraform

Page last updated:

This guide describes the preparation steps required to deploy Ops Manager on Amazon Web Services (AWS) using Terraform templates.

The Terraform template for Ops Manager on AWS describes a set of AWS resources and properties. For more information about how Terraform creates resources in AWS, see the [AWS Provider](#) topic on the Terraform site.

If you are deploying Pivotal Application Service (PAS), you may also find it helpful to review different deployment options in the [Reference Architecture for Pivotal Cloud Foundry on AWS](#).

Prerequisites

Before you deploy Ops Manager on AWS, review the following:

- If you intend to install PAS, see [PCF on AWS Requirements](#).
- If you intend to install Pivotal Container Service (PKS), see [AWS Prerequisites and Resource Requirements](#).

In addition to reviewing the prerequisites for your runtime, ensure you have the following:

- The [Terraform CLI](#)
- In your AWS account, ensure you have an IAM user with the following permissions:
 - AmazonEC2FullAccess
 - AmazonRDSFullAccess
 - AmazonRoute53FullAccess
 - AmazonS3FullAccess
 - AmazonVPCFullAccess
 - IAMFullAccess
 - AWSKeyManagementServicePowerUser

Step 1: Download Templates and Edit Variables File

Before you can run Terraform commands to provision infrastructure resources, you must download the AWS Terraform templates and create a Terraform template variables file as described below:

1. On [Pivotal Network](#), navigate to the **Pivotal Application Service (formerly Elastic Runtime)** release.
2. Download the AWS Terraform templates ZIP file.
3. Extract the contents of the ZIP file.
4. Move the extracted folder to the `workspace` directory on your local machine.
5. On the command line, navigate to the directory. For example:

```
$ cd ~/workspace/pivotal-cf-terraforming-aws
```

6. Navigate to the `terraforming-pas` or `terraforming-pks` directory that contains the Terraform files for your runtime.
7. In the runtime directory, create a text file named `terraform.tfvars`.
8. Open the `terraform.tfvars` file and add the following:

```
env_name      = "YOUR-ENVIRONMENT-NAME"
access_key    = "YOUR-ACCESS-KEY"
secret_key    = "YOUR-SECRET-KEY"
region        = "YOUR-AWS-REGION"
availability_zones = ["YOUR-AZ-1", "YOUR-AZ-2", "YOUR-AZ-3"]
ops_manager_ami = "YOUR-OPS-MAN-IMAGE-AMI"
dns_suffix    = "YOUR-DNS-SUFFIX"

ssl_cert = <<SSL_CERT
-----BEGIN CERTIFICATE-----
YOUR-CERTIFICATE
-----END CERTIFICATE-----
SSL_CERT

ssl_private_key = <<SSL_KEY
-----BEGIN EXAMPLE RSA PRIVATE KEY-----
YOUR-PRIVATE-KEY
-----END EXAMPLE RSA PRIVATE KEY-----
SSL_KEY
```

9. Edit the values in the file according to the table below.

| Value to replace | Guidance |
|--|--|
| <code>YOUR-ENVIRONMENT-NAME</code> | <p>Enter a name to use to identify resources in AWS. Terraform prepends the names of the resources it creates with this environment name.</p> <p> Note: You can only enter lowercase alphanumeric characters and hyphens. Examples include <code>pcf</code>, <code>pas</code>, and <code>pks</code>.</p> |
| <code>YOUR-ACCESS-KEY</code> | Enter your AWS Access Key ID of the AWS account in which you want Terraform to create resources. |
| <code>YOUR-SECRET-KEY</code> | Enter your AWS Secret Access Key of the AWS account in which you want Terraform to create resources. |
| <code>YOUR-AWS-REGION</code> | Enter the name of the AWS region in which you want Terraform to create resources. Example: <code>us-central1</code> . |
| <code>YOUR-AZ-1</code> <code>YOUR-AZ-2</code> <code>YOUR-AZ-3</code> | Enter three availability zones from your region. Example: <code>us-central-1a</code> , <code>us-central-1b</code> , <code>us-central-1c</code> . |
| <code>YOUR-OPS-MAN-IMAGE-AMI</code> | <p>Enter the source code for the Ops Manager Amazon Machine Image (AMI) you want to boot. You can find this code in the PDF included with the Ops Manager release on Pivotal Network .</p> <p>If you want to encrypt your Ops Manager VM, create an encrypted AMI copy from the AWS EC2 dashboard and enter the source code for the copied Ops Manager image instead. For more information about copying an AMI, see step 9 of Launch an Ops Manager AMI in the manual AWS configuration topic.</p> <p>To prevent the creation of an Ops Manager VM, set this value to an empty string (<code>" "</code>). When using Platform Automation, you must disable the creation of the Ops Manager VM from Terraform. For more information, see Platform Automation .</p> |
| <code>YOUR-DNS-SUFFIX</code> | Enter a domain name to use as part of the system domain for your deployment. Terraform creates DNS records in AWS using <code>YOUR-ENVIRONMENT-NAME</code> and <code>YOUR-DNS-SUFFIX</code> . For example, if you enter <code>example.com</code> for your DNS suffix and have <code>pcf</code> as your environment name, Terraform will create DNS records at <code>pcf.example.com</code> . |
| <code>YOUR-CERTIFICATE</code> | <p>Enter a certificate to use for HTTP load balancing. For production environments, use a certificate from a Certificate Authority (CA). For test environments, you can use a self-signed certificate.</p> <p>Your certificate must specify your system domain as the common name. Your system domain is <code>YOUR-ENVIRONMENT-NAME.YOUR-DNS-SUFFIX</code>.</p> <p>It also must include the following subdomains: <code>*.sys.YOUR-SYSTEM-DOMAIN</code>, <code>*.login.sys.YOUR-SYSTEM-DOMAIN</code>, <code>*.uaa.sys.YOUR-SYSTEM-DOMAIN</code>, <code>*.apps.YOUR-SYSTEM-DOMAIN</code>.</p> |
| <code>YOUR-PRIVATE-KEY</code> | Enter a private key for the certificate you entered. |

Step 2: Add Optional Variables

Complete this step if you want to do any of the following in PAS:

- Use an AWS Relational Database Service (RDS) for your deployment. For more information, see [Getting started with Amazon RDS](#) in Amazon RDS resources.
- Deploy the Isolation Segment tile.

In your `terraform.tfvars` file, specify the appropriate variables from the sections below.

 **Note:** You can see the configurable options by opening the `variables.tf` file and looking for variables with default values.

Isolation Segments

If you plan to deploy the Isolation Segment tile, add the following variables to your `terraform.tfvars` file, replacing `YOUR-CERTIFICATE` and `YOUR-PRIVATE-KEY` with a certificate and private key. This causes terraform to create an additional HTTP load balancer across three availability zones to use for the Isolation Segment tile.

```
create_isoseg_resources = 1

iso_seg_ssl_cert = <<ISO_SEG_SSL_CERT
-----BEGIN CERTIFICATE-----
YOUR-CERTIFICATE
-----END CERTIFICATE-----
ISO_SEG_SSL_CERT

iso_seg_ssl_cert_private_key = <<ISO_SEG_SSL_KEY
-----BEGIN EXAMPLE RSA PRIVATE KEY-----
YOUR-PRIVATE-KEY
-----END EXAMPLE RSA PRIVATE KEY-----
ISO_SEG_SSL_KEY
```

RDS

1. If you want to use an RDS for Ops Manager and PAS, add the following to your `terraform.tfvars` file:

```
rds_instance_count = 1
```

2. If you want to specify a username for RDS authentication, add the following variable to your `terraform.tfvars` file.

```
rds_db_username = "your-database-name"
```

Step 3: Create AWS Resources with Terraform

Follow these steps to use the Terraform CLI to create resources on AWS:

1. From the directory that contains the Terraform files, run `terraform init` to initialize the directory based on the information you specified in the `terraform.tfvars` file.

```
terraform init
```

1. Run `terraform plan -out=plan` to create the execution plan for Terraform.

```
terraform plan -out=plan
```

1. Run `terraform apply plan` to execute the plan from the previous step. It may take several minutes for Terraform to create all the resources in AWS.

```
terraform apply plan
```

Step 4: Create DNS Record

1. In a browser, navigate to the DNS provider for the DNS suffix you entered in your `terraform.tfvars` file.
2. Create a new NS record for your system domain. Your system domain is `YOUR-ENVIRONMENT-NAME.YOUR-DNS-SUFFIX`.
3. In this record, enter the name servers included in `env_dns_zone_name_servers` from your Terraform output.

What to Do Next

Proceed to the next step in the deployment, [Configuring BOSH Director on AWS Using Terraform](#).

Configuring BOSH Director on AWS Using Terraform

Page last updated:

This topic describes how to configure the BOSH Director tile in Ops Manager on Amazon Web Services (AWS) after [Deploying Ops Manager on AWS Using Terraform](#).

 **Note:** You can also perform the procedures in this topic using the Ops Manager API. For more information, see the [Using the Ops Manager API](#) topic.

Prerequisites

To complete the procedures in this topic, you must have access to the output from when you ran `terraform apply` to create resources for this deployment. You can view this output at any time by running `terraform output`. You use the values in your Terraform output to configure the BOSH Director tile.

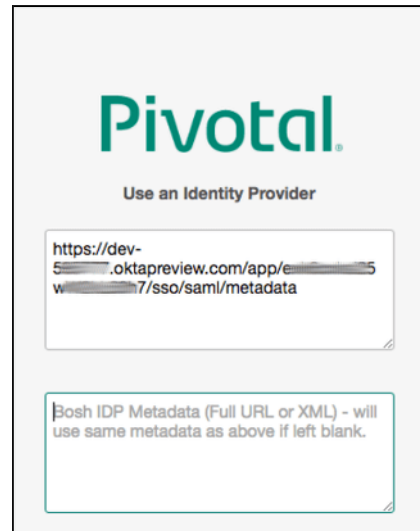

Step 1: Access Ops Manager

1. In a web browser, navigate to the fully qualified domain name (FQDN) of Ops Manager. Use the `ops_manager_dns` value from running `terraform output`.
2. When Ops Manager starts for the first time, you must choose one of the following:
 - [Use an Identity Provider](#): If you use an Identity Provider, an external identity server maintains your user database.
 - [Internal Authentication](#): If you use Internal Authentication, Ops Manager maintains your user database.

Use an Identity Provider (IdP)

1. Log in to your IdP console and download the IdP metadata XML. Optionally, if your IdP supports metadata URL, you can copy the metadata URL instead of the XML.

2. Copy the IdP metadata XML or URL to the Ops Manager **Use an Identity Provider** login page.

Note: The same IdP metadata URL or XML is applied for the BOSH Director. If you use a separate IdP for BOSH, copy the metadata XML or URL from that IdP and enter it into the BOSH IdP Metadata text box in the Ops Manager login page.

3. Enter values for the fields listed below. Failure to provide values in these fields results in a `500` error.

Note: These attributes are case-sensitive.

- **SAML admin group:** Enter the name of the SAML group that contains all Ops Manager administrators.
- **SAML groups attribute:** Enter the groups attribute tag name with which you configured the SAML server.

4. Enter your **Decryption passphrase**. Read the **End User License Agreement**, and select the checkbox to accept the terms.

5. Your Ops Manager login page appears. Enter your username and password. Click **Login**.

6. Download your SAML Service Provider metadata (SAML Relying Party metadata) by navigating to the following URLs:

- **6a.** Ops Manager SAML service provider metadata: `https://OPS-MAN-FQDN:443/uaa/saml/metadata`
- **6b.** BOSH Director SAML service provider metadata: `https://BOSH-IP-ADDRESS:8443/saml/metadata`

Note: To retrieve your `BOSH-IP-ADDRESS`, navigate to the **BOSH Director** tile > **Status** tab. Record the **BOSH Director** IP address.

7. Configure your IdP with your SAML Service Provider metadata. Import the Ops Manager SAML provider metadata from Step 6a above to your IdP. If your IdP does not support importing, provide the values below.

- **Single sign on URL:** `https://OPS-MAN-FQDN:443/uaa/saml/SSO/alias/OPS-MAN-FQDN`
- **Audience URI (SP Entity ID):** `https://OP-MAN-FQDN:443/uaa`
- **Name ID:** Email Address
- SAML authentication requests are always signed

8. Import the BOSH Director SAML provider metadata from Step 6b to your IdP. If the IdP does not support an import, provide the values below.

- **Single sign on URL:** `https://BOSH-IP:8443/saml/SSO/alias/BOSH-IP`
- **Audience URI (SP Entity ID):** `https://BOSH-IP:8443`
- **Name ID:** Email Address
- SAML authentication requests are always signed

9. Return to the **BOSH Director** tile, and continue with the configuration steps below.

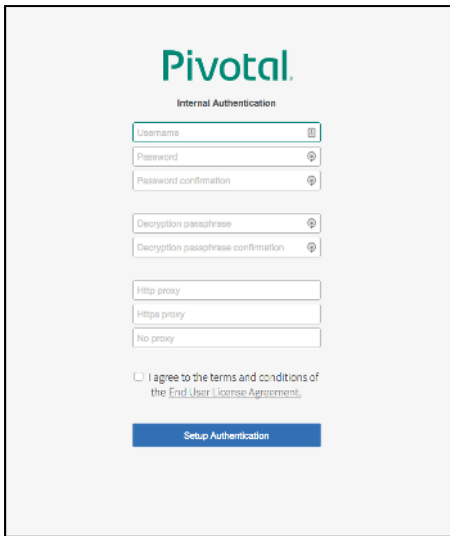

Internal Authentication

1. When redirected to the **Internal Authentication** page, you must complete the following steps:

- Enter a **Username**, **Password**, and **Password confirmation** to create an Admin user.
- Enter a **Decryption passphrase** and the **Decryption passphrase confirmation**. This passphrase encrypts the Ops Manager datastore, and is not

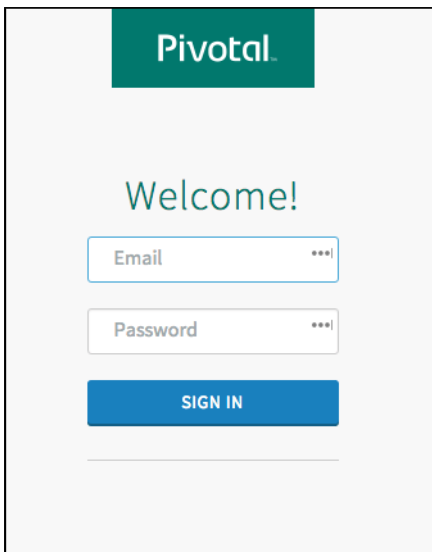

recoverable if lost.

- If you are using an **HTTP proxy** or **HTTPS proxy**, follow the instructions in the [Configuring Proxy Settings for the BOSH CPI](#) topic.
- Read the **End User License Agreement**, and select the checkbox to accept the terms.
- Click **Setup Authentication**.

The image shows the 'Internal Authentication' setup page in Pivotal. At the top is the Pivotal logo. Below it, the title 'Internal Authentication' is centered. The form contains several input fields: 'Username', 'Password', 'Password confirmation', 'Decryption passphrase', and 'Decryption passphrase confirmation'. Each of these fields has a small icon to its right. Below these are three radio button options for 'Http proxy', 'Https proxy', and 'No proxy'. At the bottom, there is a checkbox labeled 'I agree to the terms and conditions of the End User License Agreement' and a blue button labeled 'Setup Authentication'.

2. Log in to Ops Manager with the Admin username and password that you created in the previous step.

The image shows the Pivotal 'Welcome!' login page. At the top is the Pivotal logo. Below it, the word 'Welcome!' is displayed in a large, teal font. Underneath are two input fields: 'Email' and 'Password', both with masked characters (***). Below the password field is a blue button labeled 'SIGN IN'. At the bottom of the page, there is a thin horizontal line.

Step 2: AWS Config Page

1. Click the **BOSH Director** tile.

2. Select **AWS Config** to open the **AWS Management Console Config** page.

3. Select **Use AWS Keys** or **Use AWS Instance Profile**.

- If you choose to use AWS keys, complete the following fields:
 - **Access Key ID:** Enter the value of `ops_manager_iam_user_access_key` from the Terraform output.
 - **AWS Secret Key:** Enter the value of `ops_manager_iam_user_secret_key` from the Terraform output.
- If you choose to use an AWS instance profile, enter the name of your AWS Identity and Access Management (IAM) profile or enter the value of `ops_manager_iam_instance_profile_name` from the Terraform output.

4. Complete the remainder of the **AWS Management Console Config** page with the following information.

- **Security Group ID:** Enter the value of `vms_security_group_id` from the Terraform output.
- **Key Pair Name:** Enter the value of `ops_manager_ssh_public_key_name` from the Terraform output.
- **SSH Private Key:** Run `terraform output` to view the value of `ops_manager_ssh_private_key` and enter it into this field. `ops_manager_ssh_private_key` is a sensitive value and does not display when you run `terraform apply`.
- **Region:** Select the region where you deployed Ops Manager.
- **Encrypt EBS Volumes:** Select this checkbox to enable full encryption on persistent disks of all BOSH-deployed virtual machines (VMs), except for the Ops Manager VM and BOSH Director VM. See the [Configuring Amazon EBS Encryption](#) topic for details about using Elastic Block Store (EBS) encryption.

Note: Enabling EBS encryption only encrypts Linux VMs. The Windows VMs deployed with Pivotal Application Service for Windows (PASW) are not encrypted.

- **Custom Encryption Key (Optional)** Once you enable EBS encryption, you may want to specify a custom Key Management Service (KMS) encryption key. If you don't enter a value, your custom encryption key will default to the account key. For more information, see [Configuring Amazon EBS Encryption](#).

5. Click **Save**.

Step 3: Director Config Page

1. Select **Director Config** to open the **Director Config** page.

Director Config

NTP Servers (comma delimited)*

0.amazon.pool.ntp.org, 1.amazon.pool.ntp.org

JMX Provider IP Address

Bosh HM Forwarder IP Address

☐ Enable VM Resurrector Plugin

☐ Enable Post Deploy Scripts

☐ Recreate all VMs

This will force BOSH to recreate all VMs on the next deploy. Persistent disk will be preserved

☐ Enable bosh deploy retries

This will attempt to re-deploy a failed deployment up to 5 times.

☐ Keep Unreachable Director VMs

2. Enter at least two of the following NTP servers in the **NTP Servers (comma delimited)** field, separated by a comma:

0.amazon.pool.ntp.org, 1.amazon.pool.ntp.org, 2.amazon.pool.ntp.org, 3.amazon.pool.ntp.org

Note: The NTP server configuration only updates after VM recreation. Ensure that you select the **Recreate all VMs** checkbox if you modify the value of this field.

3. Leave the **JMX Provider IP Address** field blank.

Note: Starting in PAS v2.0, BOSH-reported component metrics are available in the Loggregator Firehose by default. Therefore, if you continue to use PCF JMX Bridge for consuming them outside of the Firehose, you may receive duplicate data. To prevent this, leave the **JMX Provider IP Address** field blank. For additional guidance, see [BOSH System Metrics Available in Loggregator Firehose](#).

4. Leave the **Bosh HM Forwarder IP Address** field blank.

Note: Starting in PAS v2.0, BOSH-reported component metrics are available in the Loggregator Firehose by default. Therefore, if you continue to use the BOSH HM Forwarder for consuming them, you may receive duplicate data. To prevent this, leave the **Bosh HM Forwarder IP Address** field blank. For additional guidance, see [BOSH System Metrics Available in Loggregator Firehose](#).

5. Select the **Enable VM Resurrector Plugin** checkbox to enable the Ops Manager Resurrector functionality and increase your runtime availability.
6. Select **Enable Post Deploy Scripts** to run a post-deploy script after deployment. This script allows the job to execute additional commands against a deployment.

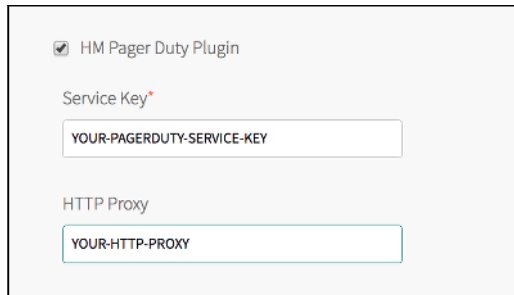

Note: You must enable post-deploy scripts to install PKS.

7. Select **Recreate all VMs** to force BOSH to recreate all VMs on the next deploy. This process does not destroy any persistent disk data.
8. Select **Enable bosh deploy retries** if you want Ops Manager to retry failed BOSH operations up to five times.
9. (Optional) Disable **Allow Legacy Agents** if all of your tiles have stemcells v3468 or later. Disabling the field will allow Ops Manager to implement TLS

secure communications.

10. Select **Keep Unreachable Director VMs** if you want to preserve BOSH Director VMs after a failed deployment for troubleshooting purposes.

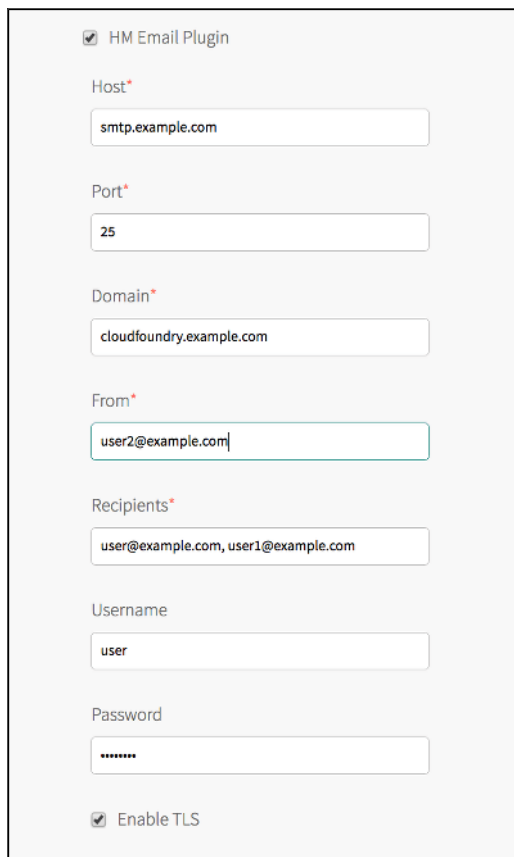

11. Select **HM Pager Duty Plugin** to enable Health Monitor integration with PagerDuty.

The screenshot shows a configuration form for the 'HM Pager Duty Plugin'. It includes a checked checkbox for the plugin name. Below it, there is a 'Service Key' field with a red asterisk, containing the placeholder text 'YOUR-PAGERDUTY-SERVICE-KEY'. Further down is an 'HTTP Proxy' field containing the placeholder text 'YOUR-HTTP-PROXY'.

- **Service Key:** Enter your API service key from PagerDuty.
- **HTTP Proxy:** Enter an HTTP proxy for use with PagerDuty.

12. Select **HM Email Plugin** to enable Health Monitor integration with email.

The screenshot shows a configuration form for the 'HM Email Plugin'. It includes a checked checkbox for the plugin name. Below it are several fields: 'Host' (smtp.example.com), 'Port' (25), 'Domain' (cloudfoundry.example.com), 'From' (user2@example.com), 'Recipients' (user@example.com, user1@example.com), 'Username' (user), and 'Password' (masked with dots). At the bottom, there is a checked checkbox for 'Enable TLS'.

- **Host:** Enter your email hostname.
- **Port:** Enter your email port number.
- **Domain:** Enter your domain.
- **From:** Enter the address for the sender.
- **Recipients:** Enter comma-separated addresses of intended recipients.
- **Username:** Enter the username for your email server.
- **Password:** Enter the password for your email server.
- **Enable TLS:** Select this checkbox to enable Transport Layer Security.

13. For **CredHub Encryption Provider**, you can choose whether BOSH CredHub stores its encryption key internally on the BOSH Director and CredHub VM, or in an external hardware security module (HSM). The HSM option is more secure.

Before configuring an HSM encryption provider in the **Director Config** pane, you must follow the procedures and collect information described in [Preparing CredHub HSMs for Configuration](#).

 **Note:** After you deploy Ops Manager with an HSM encryption provider, you cannot change BOSH CredHub to store encryption keys internally.

CredHub Encryption Provider

☒ Internal
 ☐ Luna HSM

Encryption Key Name*

Provider Partition*

Provider Partition Password*

Provider Client Certificate*

Provider Client Certificate Private Key*

HSM Host Address*

HSM Port Address*

Partition Serial Number*

HSM Certificate*

- **Internal:** Select this option for internal CredHub key storage. This option is selected by default and requires no additional configuration.
- **Luna HSM:** Select this option to use a SafeNet Luna HSM as your permanent CredHub encryption provider, and fill in the following fields:
 1. **Encryption Key Name:** Any name to identify the key that the HSM uses to encrypt and decrypt the CredHub data. Changing this key name after you deploy Ops Manager can cause service downtime.
 2. **Provider Partition:** The partition that stores your encryption key. Changing this partition after you deploy Ops Manager could cause service downtime. For this value and the ones below, use values gathered in [Preparing CredHub HSMs for Configuration](#).
 3. **Provider Partition Password**
 4. **Provider Client Certificate:** The certificate that validates the identity of the HSM when CredHub connects as a client.
 5. **Provider Client Certificate Private Key**
 6. **HSM Host Address**
 7. **HSM Port Address:** If you do not know your port address, enter `1792`.
 8. **Partition Serial Number**

9. **HSM Certificate:** The certificate that the HSM presents to CredHub to establish a two-way mTLS connection.

14. Select a **Blobstore Location** to either configure the blobstore as an internal server or an external endpoint. Because the internal server is unscalable and less secure, Pivotal recommends that you configure an external blobstore.

 **Note:** After you deploy Ops Manager, you cannot change the blobstore location.

Blobstore Location

☒ Internal

☐ S3 Compatible Blobstore

S3 Endpoint*

Bucket Name*

Access Key*

Secret Key*

☒ V2 Signature

☐ V4 Signature

Region*

☐ GCS Blobstore

Bucket Name*

Storage Class*

Regional

Service Account Key*

- **Internal:** Select this option to use an internal blobstore. Ops Manager creates a new VM for blob storage. No additional configuration is required.
- **S3 Compatible Blobstore:** Select this option to use an external S3-compatible endpoint. When you have created an S3 bucket, complete the following steps:
 1. **S3 Endpoint:** Navigate to the [Regions and Endpoints](#) topic in the AWS documentation.
 - a. Locate the endpoint for your region in the **Amazon Simple Storage Service (S3)** table and construct a URL using your region's endpoint. For example, if you are using the `us-west-2` region, the URL you create would be `https://s3-us-west-2.amazonaws.com`. Enter this URL into the **S3 Endpoint** field.
 - b. On a command line, run `ssh ubuntu@OPS-MANAGER-FQDN` to SSH into the Ops Manager VM. Replace `OPS-MANAGER-FQDN` with the fully qualified domain name of Ops Manager.
 - c. Copy the custom public CA certificate you used to sign the S3 endpoint into `/etc/ssl/certs` on the Ops Manager VM.
 - d. On the Ops Manager VM, run `sudo update-ca-certificates -f -v` to import the custom CA certificate into the Ops Manager VM truststore.

 **Note:** You must also add this custom CA certificate into the **Trusted Certificates** field in the **Security** page. See [Security Page](#) for instructions.

2. **Bucket Name:** Enter the name of the S3 bucket.
3. **Access Key** and **Secret Key:** Enter the keys you generated when creating your S3 bucket.
4. Select **V2 Signature** or **V4 Signature**. If you select **V4 Signature**, enter your **Region**.

 **Note:** AWS recommends using Signature Version 4. For more information about AWS S3 Signatures, see [Authenticating Requests](#) in the AWS documentation.

- **Enable TLS:** Select this checkbox to enable TLS.

 **Note:** If you are using Linux stemcells, make sure you have configured [Linux stemcell v3586.16 or later](#) for all tiles before enabling TLS.

 **Note:** If you are using PAS for Windows 2016, make sure you have configured [Windows stemcell v1709.10 or later](#) for all tiles before enabling TLS.

- **GCS Blobstore:** Select this option to use an external GCS endpoint. To create a GCS bucket, you must have a GCS account. Follow the procedures in [Creating Storage Buckets](#) in the GCS documentation to create a GCS bucket. When you have created a GCS bucket, complete the following steps:
 1. **Bucket Name:** Enter the name of your GCS bucket.
 2. **Storage Class:** Select the storage class for your GCS bucket. See [Storage Classes](#) in the GCP documentation for more information.
 3. **Service Account Key:** Follow the steps in the [Set up an IAM Service Account](#) section of *Preparing to Deploy Ops Manager on GCP Manually* to download a JSON file with a private key. Enter the contents of the JSON file into the field.

15. For **Database Location**, if you choose to configure an external MySQL database with Amazon Relational Database Service (RDS) or another service, select **External MySQL Database** and complete the fields below. Otherwise, select **Internal**. For more information about creating a RDS MySQL instance, see [Creating a MySQL DB Instance](#) in the AWS documentation.

- **Host:** Enter the value of your host.
- **Port:** Enter your port number. For example, `3306`.
- **Username:** Enter your username.
- **Password:** Enter your password.
- **Database:** Enter your database name.

In addition, if you selected the **Enable TLS for Director Database** checkbox, you can fill out the following optional fields:

- **Enable TLS:** Selecting this checkbox enables TLS communication between the BOSH Director and the database.
- **TLS CA:** Enter the Certificate Authority for the TLS Certificate.
- **TLS Certificate:** Enter the client certificate for mutual TLS connections to the database.
- **TLS Private Key:** Enter the client private key for mutual TLS connections to the database.
- **Advanced DB Connection Options:** If you would like to provide additional options for the database, use this field to provide a JSON-formatted options string.

16. (Optional) **Director Workers** sets the number of workers available to execute Director tasks. This field defaults to `5`.
17. (Optional) **Max Threads** sets the maximum number of threads that the BOSH Director can run simultaneously. Pivotal recommends that you leave the field blank to use the default value, unless doing so results in rate limiting or errors on your IaaS.
18. (Optional) To add a custom URL for your BOSH Director, enter a valid hostname in **Director Hostname**. You can also use this field to configure a load balancer in front of your BOSH Director. For more information, see [How to set up a load balancer in front of BOSH Director](#) in the Pivotal Knowledge Base.

 **warning:** In Ops Manager v2.2.7 and earlier, if you change the **Director Hostname** after your initial deployment, VMs become unavailable. This causes downtime. To restore VM availability, enable **Recreate All VMs** and redeploy. This issue is resolved in [Ops Manager v2.2.8](#) and later.

19. (Optional) Enter your list of comma-separated **Excluded Recursors** to declare which IP addresses and ports should not be used by the DNS server.
20. (Optional) To disable BOSH DNS, select the **Disable BOSH DNS server for troubleshooting purposes** checkbox. For more information about the BOSH DNS service discovery mechanism, see [BOSH DNS Enabled by Default](#) in the Ops Manager v2.2 Release Notes.

 **Breaking Change:** Do not disable BOSH DNS without consulting Pivotal Support.

21. (Optional) To set a custom banner that users see when logging in to the Director using SSH, enter text in the **Custom SSH Banner** field.

☐ Disable BOSH DNS server for troubleshooting purposes

Custom SSH Banner

22. (Optional) Enter your comma-separated custom **Identification Tags**. For example, `iaas:foundation1, hello:world`. You can use the tags to identify your foundation when viewing VMs or disks from your IaaS.

23. Click **Save**.

 **Note:** For more information about AWS S3 Signatures, see the AWS [Authenticating Requests](#)  documentation.

Step 4: Create Availability Zones Page

1. Select **Create Availability Zones**.

Create Availability Zones

Availability Zones

Add

▼ us-west-1c

Amazon Availability Zone*

us-west-1c

The Amazon Availability Zone name (ex: 'us-east-1b')

Save

2. Use the following steps to create three Availability Zones for your apps to use:
 - a. Click **Add** three times.
 - b. For **Amazon Availability Zone**, enter the values corresponding to the key `infrastructure_subnet_availability_zones` from the Terraform output.
 - c. Click **Save**.

Step 5: Create Networks Page

Create Networks

Warning: Pivotal recommends keeping the IP settings throughout the life of your installation. Ops Manager may prevent you from changing them in the future.
Contact Pivotal support for help completing such a change.

Verification Settings

☐ Enable ICMP checks

Networks

One or many IP ranges upon which your products will be deployed

▼ Infrastructure

Name*

Subnets

VPC Subnet ID*

CIDR*

Reserved IP Ranges

DNS*

Gateway*

Availability Zones*

☒ us-west-2a
 ☐ us-west-2b
 ☐ us-west-2c

- Select **Create Networks**.
- (Optional) Select **Enable ICMP checks** to enable ICMP on your networks. Ops Manager uses ICMP checks to confirm that components within your network are reachable.
- To add the network configuration you created for your VPC, do the following:
 - Click **Add Network**.
 - For **Name**, enter `infrastructure`.
 - Create a subnet for each availability zone by clicking **Add Subnet**. Refer to the table below for the information required to create all three subnets:

| | | |
|--------------|--------------------|---|
| First Subnet | VPC Subnet ID | The first value of <code>infrastructure_subnet_ids</code> from the Terraform output. |
| | CIDR | <code>10.0.16.0/28</code> |
| | Reserved IP Ranges | <code>10.0.16.0-10.0.16.4</code> |
| | DNS | <code>10.0.0.2</code> * |
| | Gateway | <code>10.0.16.1</code> |
| | Availability Zones | The first value of <code>infrastructure_subnet_availability_zones</code> from the Terraform output. |

| | | |
|---------------|--------------------|--|
| Second Subnet | VPC Subnet ID | The second value of <code>infrastructure_subnet_ids</code> from the Terraform output. |
| | CIDR | <code>10.0.16.16/28</code> |
| | Reserved IP Ranges | <code>10.0.16.16–10.0.16.20</code> |
| | DNS | <code>10.0.0.2</code> * |
| | Gateway | <code>10.0.16.17</code> |
| | Availability Zones | The second value of <code>infrastructure_subnet_availability_zones</code> from the Terraform output. |
| Third Subnet | VPC Subnet ID | The third value of <code>infrastructure_subnet_ids</code> from the Terraform output. |
| | CIDR | <code>10.0.16.32/28</code> |
| | Reserved IP Ranges | <code>10.0.16.32–10.0.16.36</code> |
| | DNS | <code>10.0.0.2</code> * |
| | Gateway | <code>10.0.16.33</code> |
| | Availability Zones | The third value of <code>infrastructure_subnet_availability_zones</code> from the Terraform output. |

* If you set a VPC CIDR other than recommended, enter the second IP in your VPC CIDR. For example, for a `10.0.0.0/24` VPC CIDR, enter `10.0.0.2` in each subnet.

- d. Click **Add Network**.
- e. For **Name**, enter the name of your runtime. For example, `pas`.
- f. Create a subnet for each availability zone by clicking **Add Subnet**. Refer to the table below for the information required to create all three subnets:

| | | |
|---------------|--------------------|---|
| First Subnet | VPC Subnet ID | The first value of <code>pas_subnet_ids</code> from the Terraform output. |
| | CIDR | <code>10.0.4.0/24</code> |
| | Reserved IP Ranges | <code>10.0.4.0–10.0.4.4</code> |
| | DNS | <code>10.0.0.2</code> * |
| | Gateway | <code>10.0.4.1</code> |
| | Availability Zones | The first value of <code>pas_subnet_availability_zones</code> from the Terraform output. |
| Second Subnet | VPC Subnet ID | The second value of <code>pas_subnet_ids</code> from the Terraform output. |
| | CIDR | <code>10.0.5.0/24</code> |
| | Reserved IP Ranges | <code>10.0.5.0–10.0.5.4</code> |
| | DNS | <code>10.0.0.2</code> * |
| | Gateway | <code>10.0.5.1</code> |
| | Availability Zones | The second value of <code>pas_subnet_availability_zones</code> from the Terraform output. |
| Third Subnet | VPC Subnet ID | The third value of <code>pas_subnet_ids</code> from the Terraform output. |
| | CIDR | <code>10.0.6.0/24</code> |
| | Reserved IP Ranges | <code>10.0.6.0–10.0.6.4</code> |
| | DNS | <code>10.0.0.2</code> * |
| | Gateway | <code>10.0.6.1</code> |
| | Availability Zones | The third value of <code>pas_subnet_availability_zones</code> from the Terraform output. |

* If you set a VPC CIDR other than recommended, enter the second IP in your VPC CIDR. For example, for a `10.0.0.0/24` VPC CIDR, enter `10.0.0.2` in each subnet.

- g. Click **Add Network**.
- h. For **Name**, enter `services`.
- i. Create a subnet for each availability zone by clicking **Add Subnet**. Refer to the table below for the information required to create all three subnets:

| | | |
|-------|--------------------|--|
| First | VPC Subnet ID | The first value of <code>services_subnet_ids</code> from the Terraform output. |
| | CIDR | <code>10.0.8.0/24</code> |
| | Reserved IP Ranges | <code>10.0.8.0–10.0.8.3</code> |

| | | |
|---------------|--------------------|--|
| Subnet | DNS | 10.0.0.2 * |
| | Gateway | 10.0.8.1 |
| | Availability Zones | The first value of <code>services_subnet_availability_zones</code> from the Terraform output. |
| Second Subnet | VPC Subnet ID | The second value of <code>services_subnet_ids</code> from the Terraform output. |
| | CIDR | 10.0.9.0/24 |
| | Reserved IP Ranges | 10.0.9.0-10.0.9.3 |
| | DNS | 10.0.0.2 * |
| | Gateway | 10.0.9.1 |
| | Availability Zones | The second value of <code>services_subnet_availability_zones</code> from the Terraform output. |
| Third Subnet | VPC Subnet ID | The third value of <code>services_subnet_ids</code> from the Terraform output. |
| | CIDR | 10.0.10.0/24 |
| | Reserved IP Ranges | 10.0.10.0-10.0.10.3 |
| | DNS | 10.0.0.2 * |
| | Gateway | 10.0.10.1 |
| | Availability Zones | The third value of <code>services_subnet_availability_zones</code> from the Terraform output. |

* If you set a VPC CIDR other than recommended, enter the second IP in your VPC CIDR. For example, for a 10.0.0.0/24 VPC CIDR, enter 10.0.0.2 in each subnet.

- Click **Save**.

 **Note:** If you are deploying PKS with a PKS workload load balancer, you must tag each AWS subnet with your PKS Kubernetes cluster unique identifier before you create the load balancer. For more information about tagging subnets with a PKS cluster unique identifier, see [AWS Prerequisites](#).

 **Note:** After you deploy Ops Manager, you add subnets with overlapping Availability Zones to expand your network. For more information about configuring additional subnets, see [Expanding Your Network with Additional Subnets](#).

Step 6: Assign AZs and Networks Page

- Select **Assign AZs and Networks**.
- Use the dropdown to select a **Singleton Availability Zone**. The BOSH Director installs in this availability zone (AZ).
- Use the dropdown to select the `infrastructure` network for your BOSH Director.
- Click **Save**.

Step 7: Security Page

[illegible]

1. Select **Security**.
2. In **Trusted Certificates**, enter your custom certificate authority (CA) certificates to insert into your organization's certificate trust chain. This feature enables all BOSH-deployed components in your deployment to trust custom root certificates.

To enter multiple certificates, paste your certificates one after the other. For example, format your certificates like the following:

```

-----BEGIN CERTIFICATE-----
ABCEDEFGH12345678ABCEDEFGH12345678ABCEDEFGH12345678AB
EFGH12345678ABCEDEFGH12345678ABCEDEFGH12345678ABCEDE
FGH12345678ABCEDEFGH12345678ABCEDEFGH12345678...
-----END CERTIFICATE-----

-----BEGIN CERTIFICATE-----
BCDEFGH12345678ABCEDEFGH12345678ABCEDEFGH12345678ABB
EFGH12345678ABCEDEFGH12345678ABCEDEFGH12345678ABCEDE
FGH12345678ABCEDEFGH12345678ABCEDEFGH12345678...
-----END CERTIFICATE-----

-----BEGIN CERTIFICATE-----
CDEFGH12345678ABCEDEFGH12345678ABCEDEFGH12345678ABBB
EFGH12345678ABCEDEFGH12345678ABCEDEFGH12345678ABCEDE
FGH12345678ABCEDEFGH12345678ABCEDEFGH12345678...
-----END CERTIFICATE-----

```

 Note: If you want to use Docker Registries for running app instances in Docker containers, enter the certificate for your private Docker Registry in this field. See [Using Docker Registries](#) for more information on running app instances in PAS using Docker Registries.

3. Choose **Generate passwords** or **Use default BOSH password**. Pivotal recommends that you use the **Generate passwords** option for greater security.
4. Click **Save**. To view your saved Director password, click the **Credentials** tab.

Step 8: Syslog Page

1. Select **Syslog**.

Syslog

Do you want to configure Syslog for Bosh Director?

☐ No
 ☒ Yes

Address*

The address or host for the syslog server

Port*

Transport Protocol*

TCP

⌵

☐ Enable TLS

Permitted Peer*

SSL Certificate*

Save

- (Optional) Select **Yes** to send BOSH Director system logs to a remote server.
- In the **Address** field, enter the IP address or DNS name for the remote server.
- In the **Port** field, enter the port number that the remote server listens on.
- In the **Transport Protocol** dropdown menu, select **TCP**, **UDP**, or **REL**. This selection determines which transport protocol is used to send the logs to the remote server.
- (Optional) Pivotal strongly recommends that you enable TLS encryption when forwarding logs as they may contain sensitive information. For example, these logs may contain cloud provider credentials. To enable TLS, perform the following steps.
 - In the **Permitted Peer** field, enter either the name or SHA1 fingerprint of the remote peer.
 - In the **SSL Certificate** field, enter the SSL certificate for the remote server.
- Click **Save**.

Step 9: Resource Config Page

- Select **Resource Config**.

Resource Config

| JOB | INSTANCES | PERSISTENT DISK TYPE | VM TYPE | LOAD BALANCERS | INTERNET CONNECTED |
|------------------------|--------------|----------------------|--|----------------|-------------------------------------|
| BOSH Director | Automatic: 1 | Automatic: 50 GB | Automatic: large.disk (cpu: 2, ram: 8 GB, disk: 50 GB) | | <input checked="" type="checkbox"/> |
| Master Compilation Job | 1 | None | small (cpu: 1, ram: 2 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |

Save

- Adjust any values as necessary for your deployment. Under the **Instances**, **Persistent Disk Type**, and **VM Type** fields, choose **Automatic** from the dropdown to allocate the recommended resources for the job. If the **Persistent Disk Type** field reads **None**, the job does not require persistent disk space.

Note: Pivotal recommends provisioning a BOSH Director VM with at least 8 GB memory.

Note: If you set a field to **Automatic** and the recommended resource allocation changes in a future version, Ops Manager automatically uses the new recommended allocation.

Note: If you install PASW, provision your **Master Compilation Job** with at least 100 GB of disk space.

- (Optional) Enter your AWS target group name in the **Load Balancers** column for each job. Prepend the name with `alb:`. For example, enter `alb:target-group-name`. To create an Application Load Balancer (ALB) and target group, follow the procedures in [Getting Started with Application Load Balancers](#) in the AWS documentation. Then navigate to **Target Groups** in the **EC2 Dashboard** menu to find your target group **Name**.

Note: To configure an ALB, you must have the following AWS IAM permissions.

```
"elasticloadbalancing:DescribeLoadBalancers",
"elasticloadbalancing:DeregisterInstancesFromLoadBalancer",
"elasticloadbalancing:RegisterInstancesWithLoadBalancer",
"elasticloadbalancing:DescribeTargetGroups",
"elasticloadbalancing:RegisterTargets"
```

- Click **Save**.

Step 10: (Optional) Add Custom VM Extensions

Use the Ops Manager API to add custom properties to your VMs such as associated security groups and load balancers. For more information, see [Managing Custom VM Extensions](#).

Step 11: Complete the BOSH Director Installation

- Click the **Installation Dashboard** link to return to the Installation Dashboard.
- Click **Apply Changes**. If the following ICMP error message appears, click **Ignore errors and start the install**.

PCF Ops Manager

pivotal-cli

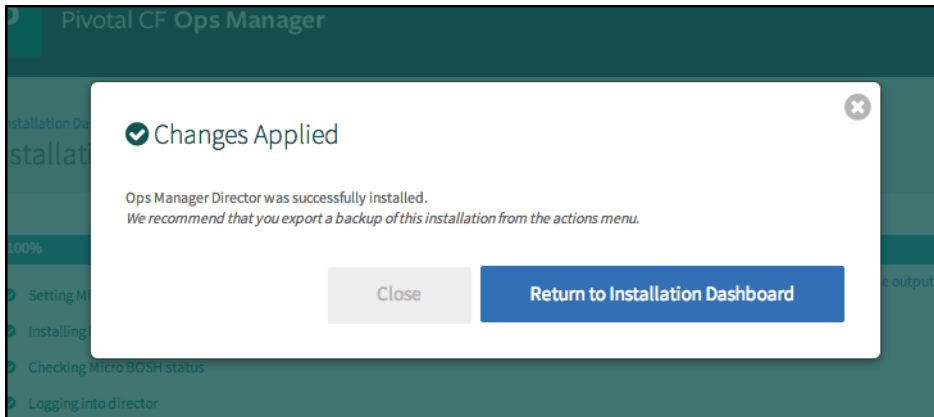

Please review the errors below

- Cannot reach gateway with IP 10.0.0.16.1 (ignorable if ICMP is disabled)
- Cannot reach DNS with IP 10.0.0.2 (ignorable if ICMP is disabled)

Ignore errors and start the install

Stop and fix errors

- BOSH Director installs. This may take a few moments. When the installation process successfully completes, the **Changes Applied** window appears.

4. After you complete this procedure, continue to the topic for the runtime you are installing:

- PAS: [Deploying PAS on AWS Using Terraform](#)
- PKS v1.2: [Installing PKS on AWS](#) 

Deploying PAS on AWS Using Terraform

Page last updated:

This topic describes how to install and configure Pivotal Application Service (PAS) on Amazon Web Services (AWS).

Before beginning this procedure, ensure that you have successfully completed the [Configuring BOSH Director on AWS Using Terraform](#) topic.

Note: If you plan to [install the PCF IPsec add-on](#), you must do so before installing any other tiles. Pivotal recommends installing IPsec immediately after Ops Manager, and before installing the PAS tile.

Step 1: Add PAS to Ops Manager

1. If you have not already downloaded PAS, log in to [Pivotal Network](#), and click PAS.
2. From the **Releases** dropdown, select the release to install and choose one of the following:
 - a. Click PAS to download the PAS `.pivotal` file.
 - b. Click **PCF Small Footprint Runtime** to download the Small Footprint Runtime `.pivotal` file. For more information, see [Getting Started with Small Footprint Runtime](#).
3. Navigate to the Pivotal Cloud Foundry Operations Manager Installation Dashboard.
4. Click **Import a Product** to add your tile to Ops Manager. For more information, refer to the [Adding and Deleting Products](#) topic.
5. Click the PAS tile in the Installation Dashboard.

Step 2: Assign Availability Zones and Networks

1. Select **Assign AZ and Networks**.
2. Select an Availability Zone under **Place singleton jobs**. Ops Manager runs any job with a single instance in this Availability Zone.
3. Select all three Availability Zones under **Balance other jobs**. Ops Manager balances instances of jobs with more than one instance across the Availability Zones that you specify.
4. From the **Network** dropdown, choose the `pas` network you created when configuring the BOSH Director tile.

Installation Dashboard

Networking

Application Containers

Application Developer Controls

Application Security Groups

Authentication and Enterprise SSO

Databases

5. Click **Save**.

Note: When you save this form, a verification error displays because the PCF security group blocks ICMP. You can ignore this error.

PCF Ops Manager

Please review the errors below

- Cannot reach gateway with IP 10.0.16.1 (ignorable if ICMP is disabled)
- Cannot reach DNS with IP 10.0.0.2 (ignorable if ICMP is disabled)

All errors will be reverified before installation.

Step 3: Configure Domains

1. Select **Domains**.

Application Service hosts applications at subdomains under its apps domain and assigns system components to subdomains under its system domain. You need to configure a wildcard DNS for both the apps domain and system domain. The two domains can be the same, although this is not recommended.

System Domain *

sys.metallicseaweed.cf-app.com

Apps Domain *

apps.metallicseaweed.cf-app.com

Save

2. Enter the system and application domains.

- For **System Domain**, enter the value of `sys_domain` from the Terraform output. This defines your target when you push apps to PAS.
- For **Apps Domain**, enter the value of `apps_domain` from the Terraform output. This defines where PAS should serve your apps.

Note: You configured a wildcard DNS record for these domains in an earlier step.

3. Click **Save**.

Step 4: Configure Networking

1. Select **Networking**.
2. Leave the **Router IPs**, **SSH Proxy IPs**, **HAProxy IPs**, and **TCP Router IPs** fields blank. You do not need to complete these fields when deploying PCF to AWS with Elastic Load Balancers (ELBs).

Note: You specify load balancers in the **Resource Config** section of Pivotal Application Service (PAS) later in the installation process. See the [Configure Router to Elastic Load Balancer](#) section of this topic for more information.

3. Under **Certificates and Private Key for HAProxy and Router**, you must provide at least one **Certificate** and **Private Key** name and certificate keypair for HAProxy and Gorouter. The HAProxy and Gorouter are enabled to receive TLS communication by default. You can configure multiple certificates for HAProxy and Gorouter.
 - a. Click the **Add** button to add a name for the certificate chain and its private keypair. This certificate is the default used by Gorouter and HAProxy.

The screenshot displays the 'Certificates and Private Keys for HAProxy and Router' configuration interface. It features two expandable sections, 'example-cert' and 'example-cert-2'. Each section contains a 'Name' input field and a large text area for the certificate and private key. The 'example-cert' section shows a pre-generated RSA certificate and private key, with a 'Generate RSA Certificate' link below it. The 'example-cert-2' section is currently empty, showing only the input fields. An 'Add' button is located in the top right corner of the configuration area.

You can either provide a certificate signed by a Certificate Authority (CA) or click on the **Generate RSA Certificate** link to generate a self-signed certificate in Ops Manager.

- b. If you want to configure multiple certificates for HAProxy and Gorouter, click the **Add** button and fill in the appropriate fields for each additional certificate keypair.

For details about generating certificates in Ops Manager for your wildcard system domains, see the [Providing a Certificate for Your SSL/TLS Termination Point](#) topic.

Note: If you configured Ops Manager Front End without a certificate, you can use this new certificate to complete Ops Manager configuration. To configure your Ops Manager Front End certificate, see [Configure Front End](https://docs.pivotal.io/pcf/om/2-2/gcp/prepare-env-manual.html#config-frontend) in [Preparing to Deploy Ops Manager on GCP Manually](https://docs.pivotal.io/pcf/om/2-2/gcp/prepare-env-manual.html#config-frontend).

Note: Ensure that you add any certificates that you generate in this pane to your infrastructure load balancer.

- (Optional) When validating client requests using mutual TLS, the Gorouter trusts multiple certificate authorities (CAs) by default. If you want to configure the Gorouter and HAProxy to trust additional CAs, enter your CA certificates under **Certificate Authorities Trusted by Router and HAProxy**. All CA certificates should be appended together into a single collection of PEM-encoded entries.

Certificate Authorities Trusted by Router and HAProxy

In addition to well-known, public CAs, and those trusted via the BOSH trusted certificates collection, these certificates can be used to validate the certificates from incoming client requests. All CA certificates should be appended together into a single collection of PEM-encoded entries.

- In the **Minimum version of TLS supported by HAProxy and Router** field, select the minimum version of TLS to use in HAProxy and Gorouter communications. HAProxy and Gorouter use TLS v1.2 by default. If you need to accommodate clients that use an older version of TLS, select a lower minimum version. For a list of TLS ciphers supported by the Gorouter, see [Securing Traffic into Cloud Foundry](#).

Minimum version of TLS supported by HAProxy and Router*

☐ TLSv1.0
 ☐ TLSv1.1
 ☒ TLSv1.2

- Configure **Logging of Client IPs in CF Router**. The **Log client IPs** option is set by default. To comply with the General Data Protection Regulation (GDPR), select one of the following options to disable logging of client IP addresses:

- If your load balancer exposes its own source IP address, disable logging of the `X-Forwarded-For` HTTP header only.
- If your load balancer exposes the source IP of the originating client, disable logging of both the source IP address and the `X-Forwarded-For` HTTP header.

Logging of Client IPs in CF Router*

☒ Log client IPs
 ☐ Disable logging of X-Forwarded-For header only
 ☐ Disable logging of both source IP and X-Forwarded-For header

To comply with GDPR, select one of the options to disable logging of client IPs. If the source IP exposed by your load balancer is its own, choose to disable logging of XFF header only. If the source IP exposed by your load balancer is that of the downstream client, choose to disable logging of the source IP also.

- Under **Configure support for the X-Forwarded-Client-Cert header**, configure PCF handles `x-forwarded-client-cert` (XFCC) HTTP headers based on where TLS is terminated for the first time in your deployment.

Configure support for the X-Forwarded-Client-Cert header. This header can be used by applications to verify the requester via mutual TLS. The option you should select depends upon where you will be terminating the TLS connection for the first time. *

☒ TLS terminated for the first time at infrastructure load balancer
 ☐ TLS terminated for the first time at HAProxy
 ☐ TLS terminated for the first time at the Router

The following table

indicates which option to choose based on your deployment layout.

| If your deployment is configured as follows: | Then select the following option: | Additional notes: |
|---|-----------------------------------|-------------------|
| <ul style="list-style-type: none"> The Load Balancer is terminating TLS, and | TLS terminated for | |

| | | |
|--|--|--|
| <ul style="list-style-type: none"> Load balancer is configured to put the client certificate from a mutual authentication TLS handshake into the X-Forwarded-Client-Cert HTTP header | <p>the first time at infrastructure load balancer (default).</p> | <p>Both HAProxy and the Gorouter forward the XFCC header when included in the request.</p> |
| <ul style="list-style-type: none"> The Load Balancer is configured to pass through the TLS handshake via TCP to the instances of HAProxy, and HAProxy instance count is > 0 | <p>TLS terminated for the first time at HAProxy.</p> | <p>HAProxy sets the XFCC header with the client certificate received in the TLS handshake. The Gorouter forwards the header.</p> <div>  Breaking Change: In the Router behavior for Client Certificates field, you cannot select the Router does not request client certificates option. </div> |
| <ul style="list-style-type: none"> The Load Balancer is configured to pass through the TLS handshake via TCP to instances of the Gorouter | <p>TLS terminated for the first time at the Gorouter.</p> | <p>The Gorouter strips the XFCC header if it is included in the request and forwards the client certificate received in the TLS handshake in a new XFCC header.</p> <p>If you have deployed instances of HAProxy, app traffic bypasses those instances in this configuration. If you have also configured your load balancer to route requests for ssh directly to the Diego Brain, consider reducing HAProxy instances to 0.</p> <div>  Breaking Change: In the Router behavior for Client Certificates field, you cannot select the Router does not request client certificates option. </div> |

For a description of the behavior of each configuration option, see [Forward Client Certificate to Applications](#).

8. To configure HAProxy to handle client certificates, select one of the following options in the **HAProxy behavior for Client Certificate Validation** field.

HAProxy behavior for Client Certificate Validation*

- ☒ HAProxy does not request client certificates.
- ☐ HAProxy requests but does not require client certificates. This option is necessary if you want to enable mTLS for applications and TLS is terminated for the first time at HAProxy

- HAProxy does not request client certificates.** This option requires mutual authentication, which makes it incompatible with XFCC option **TLS terminated for the first time at HAProxy**. HAProxy does not request client certificates, so the client does not provide them and no validation occurs. This is the default configuration.
- HAProxy requests but does not require client certificates.** The HAProxy requests client certificates in TLS handshakes, validates them when presented, but does not require them.

 **warning:** Upon upgrade, PAS will fail to receive requests if your load balancer is configured to present a client certificate in the TLS handshake with HAProxy but HAProxy has not been configured with the certificate authority used to sign it. To mitigate this issue, select **HAProxy does not request client certificates** in the **Networking** pane or configure the HAProxy with the appropriate CA.

9. To configure Gorouter behavior for handling client certificates, select one of the following options in the **Router behavior for Client Certificate Validation** field.

Router behavior for Client Certificate Validation*

- ☐ Router does not request client certificates. This option is incompatible with XFCC options "TLS terminated for the first time at HAProxy" and "TLS terminated for the first time at the Router" because these options require mutual authentication.
- ☒ Router requests but does not require client certificates.
- ☐ Router requires client certificates.

- Router does not request client certificates.** This option is incompatible with the XFCC configuration options **TLS terminated for the first time at HAProxy** and **TLS terminated for the first time at the Router** in PAS because these options require mutual authentication. As client

certificates are not requested, client will not provide them, and thus validation of client certificates will not occur.

- **Router requests but does not require client certificates.** The Gorouter requests client certificates in TLS handshakes, validates them when presented, but does not require them. This is the default configuration.
- **Router requires client certificates.** The Gorouter validates that the client certificate is signed by a Certificate Authority that the Gorouter trusts. If the Gorouter cannot validate the client certificate, the TLS handshake fails.

⚠ warning: Requests to the platform will fail upon upgrade if your load balancer is configured with client certificates and the Gorouter does not have the certificate authority. To mitigate this issue, select **Router does not request client certificates** for **Router behavior for Client Certificate Validation** in the **Networking** pane.

10. In the **TLS Cipher Suites for Router** field, review the TLS cipher suites for TLS handshakes between Gorouter and front-end clients such as load balancers or HAProxy. The default value for this field is `ECDHE-RSA-AES128-GCM-SHA256:TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384`.

💡 Note: AWS Classic Load Balancers do not support PCF's default cipher suites. See [TLS Cipher Suite Support by AWS Load Balancers](#) for information about configuring your AWS load balancers and Gorouter.

If you want to modify the default configuration, use an ordered, colon-delimited list of Golang-supported TLS cipher suites in the OpenSSL format. Operators should verify that the ciphers are supported by any clients or front-end components that will initiate TLS handshakes with Gorouter. For a list of TLS ciphers supported by Gorouter, see [Securing Traffic into Cloud Foundry](#).

TLS Cipher Suites for Router *

`ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384`

Verify that every client participating in TLS handshakes with Gorouter has at least one cipher suite in common with Gorouter.

💡 Note: Specify cipher suites that are supported by the versions configured in the **Minimum version of TLS supported by HAProxy and Router** field.

11. In the **TLS Cipher Suites for HAProxy** field, review the TLS cipher suites for TLS handshakes between HAProxy and its clients such as load balancers and Gorouter. The default value for this field is the following:
`DHE-RSA-AES128-GCM-SHA256:DHE-RSA-AES256-GCM-SHA384:ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384` If you want to modify the default configuration, use an ordered, colon-delimited list of TLS cipher suites in the OpenSSL format. Operators should verify that the ciphers are supported by any clients or front-end components that will initiate TLS handshakes with HAProxy.

TLS Cipher Suites for HAProxy *

`DHE-RSA-AES128-GCM-SHA256:DHE-RSA-AES256-GCM-SHA384:ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384`

Verify that every client participating in TLS handshakes with HAProxy has at least one cipher suite in common with HAProxy.

💡 Note: Specify cipher suites that are supported by the versions configured in the **Minimum version of TLS supported by HAProxy and Router** field.

12. Under **HAProxy forwards requests to Router over TLS**, select **Enable** or **Disable** based on your deployment layout.

HAProxy forwards requests to Router over TLS. When enabled, HAProxy will forward all requests to the Router over TLS. HAProxy will use the CA provided to verify the certificates provided by the Router. *

☒ Enable

Certificate Authority for HAProxy Backend *

You need to provide a certificate authority for the certificate and key provided in the "Certificate and Private Key for HAProxy and Router" field. HAProxy will verify those certificates using this CA when establishing a connection. If you generated that certificate and key using the "Generate RSA Certificate" feature, then your CA is the Ops Manager CA, and can be found by visiting the "/api/v0/certificate_authorities" API endpoint.

☐ Disable

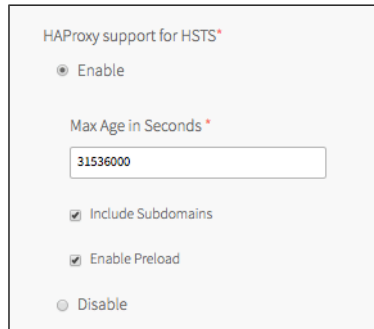

◦ Enable HAProxy forwarding of requests to Router over TLS

| If you want to: | Encrypt communication between HAProxy and the Gorouter |
|-------------------------------|---|
| Then configure the following: | <ol style="list-style-type: none"> 1. Leave Enable selected. 2. In the Certificate Authority for HAProxy Backend field, specify the Certificate Authority (CA) that signed the certificate you configured in the Certificate and Private Key for HAProxy and Router field. <div>  Note: If you used the Generate RSA Certificate link to generate a self-signed certificate, then the CA to specify is the Ops Manager CA, which you can locate at the <code>/api/v0/certificate_authorities</code> endpoint in the Ops Manager API. </div> <ol style="list-style-type: none"> 3. Make sure that Gorouter and HAProxy have TLS cipher suites in common in the TLS Cipher Suites for Router and TLS Cipher Suites for HAProxy fields. |
| See also: | <ul style="list-style-type: none"> ◦ Terminating SSL/TLS at the Load Balancer and Gorouter ◦ Providing a Certificate for Your SSL/TLS Termination Point ◦ Using the Ops Manager API |

◦ Disable HAProxy forwarding of requests to Router over TLS

| If you want to: | Use non-encrypted communication between HAProxy and Gorouter, or you are not using HAProxy |
|-------------------------------|---|
| Then configure the following: | <ol style="list-style-type: none"> 1. Select Disable. 2. If you are not using HAProxy, set the number of HAProxy job instances to <code>0</code> on the Resource Config page. See Disable Unused Resources. |
| See also: | <ul style="list-style-type: none"> ◦ Terminating SSL/TLS at the Gorouter Only ◦ Terminating SSL/TLS at the Load Balancer Only |

13. If you want to force browsers to use HTTPS when making requests to HAProxy, select **Enable** in the **HAProxy support for HSTS** field, and complete

the following optional configuration steps:

- (Optional) Enter a **Max Age in Seconds** for the HSTS request. By default, the age is set to one year. HAProxy will force HTTPS requests from browsers for the duration of this setting.
- (Optional) Select the **Include Subdomains** checkbox to force browsers to use HTTPS requests for all component subdomains.
- (Optional) Select the **Enable Preload** checkbox to force instances of Google Chrome, Firefox, and Safari that access your HAProxy to refer to their built-in lists of known hosts that require HTTPS, of which HAProxy is one. This ensures that the first contact a browser has with your HAProxy is an HTTPS request, even if the browser has not yet received an HSTS header from HAProxy.

- If you are not using SSL encryption or if you are using self-signed certificates, select **Disable SSL certificate verification for this environment**. Selecting this checkbox also disables SSL verification for route services.

 **Note:** For production deployments, Pivotal does not recommend disabling SSL certificate verification.

- (Optional) If you want HAProxy or the Gorouter to reject any HTTP (non-encrypted) traffic, select the **Disable HTTP on HAProxy and Gorouter** checkbox. When selected, HAProxy and Gorouter will not listen on port 80.

☐ Disable HTTP on HAProxy and Gorouter

- (Optional) Select the **Disable insecure cookies on the Router** checkbox to set the secure flag for cookies generated by the router.
- (Optional) To disable the addition of Zipkin tracing headers on the Gorouter, deselect the **Enable Zipkin tracing headers on the router** checkbox. Zipkin tracing headers are enabled by default. For more information about using Zipkin trace logging headers, see [Zipkin Tracing in HTTP Headers](#).
- (Optional) To stop the Router from writing access logs to local disk, deselect the **Enable Router to write access logs locally** checkbox. You should consider disabling this checkbox for high traffic deployments since logs may not be rotated fast enough and can fill up the disk.
- By default, the PAS routers handle traffic for applications deployed to an isolation segment created by the PCF Isolation Segment tile. To configure the PAS routers to reject requests for applications within isolation segments, select the **Routers reject requests for Isolation Segments** checkbox.

☐ Routers reject requests for Isolation Segments

Do not enable this option without deploying

routers for each isolation segment. See the following topics for more information:

- [Installing PCF Isolation Segment](#)
- [Sharding Routers for Isolation Segments](#)

- (Optional) By default, Gorouter support for the PROXY protocol is disabled. To enable the PROXY protocol, select **Enable support for PROXY protocol in CF Router**. When enabled, client-side load balancers that terminate TLS but do not support HTTP can pass along information from the originating client. Enabling this option may impact Gorouter performance. For more information about enabling the PROXY protocol in Gorouter, see the *HTTP Header Forwarding* sections in the [Securing Traffic in Cloud Foundry](#) topic.
- In the **Choose whether to enable route services** section, choose either **Enable route services** or **Disable route services**. Route services are a class of [marketplace services](#) that perform filtering or content transformation on application requests and responses. See the [Route Services](#) topic for details. 1. If you enabled route services, you can also configure the **Bypass security checks for route service lookup** field. Pivotal recommends that you do not enable this field because it has potential security concerns. However, you may need to enable it if your load balancer requires mutual TLS from clients. For more information, see [Configuring Route Service Lookup](#).
- (Optional) If you want to limit the number of app connections to the backend, enter a value in the **Max Connections Per Backend** field. You can use this field to prevent a poorly behaving app from all the connections and impacting other apps.

To choose a value for this field, review the peak concurrent connections received by instances of the most popular apps in your deployment. You can

determine the number of concurrent connections for an app from the `httpStartStop` event metrics emitted for each app request.

If your deployment uses PCF Metrics, you can also obtain this peak concurrent connection information from [Network Metrics](#). The default value is

Max Connections Per Backend *

500

23. Under **Enable Keepalive Connections for Router**, select **Enable** or **Disable**. Keepalive connections are enabled by default. For more information, see [Keepalive Connections](#) in *HTTP Routing*.

Enable Keepalive Connections for Router*

☒ Enable
 ☐ Disable

24. (Optional) To accommodate larger uploads over connections with high latency, increase the number of seconds in the **Router Timeout to Backends** field.
25. (Optional) Use the **Frontend Idle Timeout for Gorouter and HAProxy** field to help prevent connections from your load balancer to Gorouter or HAProxy from being closed prematurely. The value you enter sets the duration, in seconds, that Gorouter or HAProxy maintains an idle open connection from a load balancer that supports keep-alive.

In general, set the value higher than your load balancer's backend idle timeout to avoid the race condition where the load balancer sends a request before it discovers that Gorouter or HAProxy has closed the connection.

See the following table for specific guidance and exceptions to this rule:

| IaaS | Guidance |
|-------|---|
| AWS | AWS ELB has a default timeout of 60 seconds, so Pivotal recommends a value greater than <code>60</code> . |
| Azure | By default, Azure load balancer times out at 240 seconds without sending a TCP RST to clients, so as an exception, Pivotal recommends a value lower than <code>240</code> to force the load balancer to send the TCP RST. |
| GCP | GCP has a default timeout of 600 seconds. For GCP HTTP load balancers, Pivotal recommends a value greater than <code>600</code> . For GCP TCP load balancers, Pivotal recommends a value less than <code>600</code> to force the load balancer to send a TCP RST. |
| Other | Set the timeout value to be greater than that of the load balancer's backend idle timeout. |

 **Note:** Do not set a frontend idle timeout lower than six seconds.

26. (Optional) Increase the value of **Load Balancer Unhealthy Threshold** to specify the amount of time, in seconds, that the router continues to accept connections before shutting down. During this period, healthchecks may report the router as unhealthy, which causes load balancers to failover to other routers. Set this value to an amount greater than or equal to the maximum time it takes your load balancer to consider a router instance unhealthy, given contiguous failed healthchecks.
27. (Optional) Modify the value of **Load Balancer Healthy Threshold**. This field specifies the amount of time, in seconds, to wait until declaring the Router instance started. This allows an external load balancer time to register the Router instance as healthy.

Load Balancer Unhealthy Threshold *

Load Balancer Healthy Threshold *

28. (Optional) If app developers in your organization want certain HTTP headers to appear in their app logs with information from the Gorouter, specify them in the **HTTP Headers to Log** field. For example, to support app developers that deploy Spring apps to PCF, you can enter [Spring-specific HTTP headers](#).

HTTP Headers to Log

29. If you expect requests larger than the default maximum of 16 Kbytes, enter a new value (in bytes) for **HAProxy Request Max Buffer Size**. You may need to do this, for example, to support apps that embed a large cookie or query string values in headers.

30. If your PCF deployment uses HAProxy and you want it to receive traffic only from specific sources, use the following fields:

- **HAProxy Protected Domains:** Enter a comma-separated list of domains to protect from unknown source requests.
- **HAProxy Trusted CIDRs:** Optionally, enter a space-separated list of CIDRs to limit which IP addresses from the **Protected Domains** can send traffic to PCF.

HAProxy Protected Domains

A comma-separated list of domains to protect from requests from unknown sources. Use this property in conjunction with "Trusted CIDRs" to protect these domains from requests from unknown sources.

HAProxy Trusted CIDRs

31. The **Loggregator Port** defaults to if left blank. For AWS environments that are not using an Application Load Balancer, enter .

Container Network Interface Plugin*

32. For **Container Network Interface Plugin**, ensure **Silk** is selected and review the following fields:

Note: The **External** option exists to support NSX-T integration for vSphere deployments.

- (Optional) You can change the value in the **Applications Network Maximum Transmission Unit (MTU)** field. Pivotal recommends setting the MTU value for your application network to . Some configurations, such as networks that use GRE tunnels, may require a smaller MTU value.
- (Optional) Enter an IP range for the overlay network in the **Overlay Subnet** box. If you do not set a custom range, Ops Manager uses .

warning: The overlay network IP range must not conflict with any other IP addresses in your network.

- Enter a UDP port number in the **VXLAN Tunnel Endpoint Port** box. If you do not set a custom port, Ops Manager uses 4789.
- For **Denied logging interval**, set the per-second rate limit for packets blocked by either a container-specific [networking policy](#) or by [Application Security Group](#) rules applied across the space, org, or deployment. This field defaults to .
- For **UDP logging interval**, set the per-second rate limit for UDP packets sent and received. This field defaults to .
- To enable logging for app traffic, select **Log traffic for all accepted/denied application packets**. See [Manage Logging for Container-to-Container Networking](#) for more information.
- By default, containers use the same DNS servers as the host. If you want to override the DNS servers to be used in containers, enter a comma-separated list of servers in **DNS Servers**.

Note: If your deployment uses BOSH DNS, which is the default, you cannot use this field to override the DNS servers used in containers.

33. For **DNS Search Domains**, enter DNS search domains as a comma-separated list. Your containers append these search domains to hostnames to resolve them into full domain names.

DNS Search Domains

example.com, myapps.com

DNS search domains to be used in containers. A comma-separated list can be specified.

34. For **Database Connection Timeout**, set the connection timeout for clients of the policy server and silk databases. The default value is . You may need to increase this value if your deployment experiences timeout issues related to Container-to-Container Networking.

35. (Optional) TCP Routing is disabled by default. You should enable this feature if your DNS sends TCP traffic through a load balancer rather than directly to a TCP router. To enable TCP routing:
 - a. Select **Enable TCP Routing**
 - b. For **TCP Routing Ports**, enter a single port or a range of ports for the load balancer to forward to. If you [configured AWS for PCF manually](#), enter `1024-1123` which corresponds to the rules you created for `pcf-tcp-elb`.
 - To support multiple TCP routes, Pivotal recommends allocating multiple ports.
 - To allocate a list of ports rather than a range:
 1. Enter a single port in the **TCP Routing Ports** field.
 2. After deploying PAS, follow the directions in [Configuring a List of TCP Routing Ports](#) to add TCP routing ports using the cf CLI.
 - c. For AWS, you also need to specify the name of a TCP ELB in the **LOAD BALANCER** column of TCP Router job of the `Resource Config` screen. You configure this later on in PAS. For more information, see the [Configure Router to Elastic Load Balancer](#) topic.

Enable TCP requests to your apps via specific ports on the TCP router. You will want to configure a load balancer to forward these TCP requests to the TCP routers. If you do not have a load balancer, then you can also send traffic directly to the TCP router.*

☐ Select this option if you prefer to enable TCP Routing at a later time

☒ Enable TCP Routing

TCP Routing Ports (one-time configuration, if you want to update this value you can via the CF CLI) *

1024-1123

36. (Optional) To disable TCP routing, click **Select this option if you prefer to enable TCP Routing at a later time** For more information, see the [Configuring TCP Routing in PAS](#) [↗](#) topic.

37. Click **Save**

Step 5: Configure Application Containers

1. Select **Application Containers**.

Enable microservice frameworks, private Docker registries, and other services that support your applications at a container level.

- ☒ Enable Custom Buildpacks
- ☒ Allow SSH access to app containers
- ☒ Enable SSH when an app is created
- ☒ Enable the GrootFS container image plugin for Garden RunC

☐ Router uses TLS to verify application identity

Private Docker Insecure Registry Whitelist

10.10.10.10:8888,example.com:8888

Docker Images Disk-Cleanup Scheduling on Cell VMs*

- ☐ Never clean up Cell disk-space
- ☐ Routinely clean up Cell disk-space
- ☒ Clean up disk-space once threshold is reached

Threshold of Disk-Used (MB) (min: 1) *

10240

- The **Enable Custom Buildpacks** checkbox governs the ability to pass a custom buildpack URL to the `-b` option of the `cf push` command. By default, this ability is enabled, letting developers use custom buildpacks when deploying apps. Disable this option by disabling the checkbox. For more information about custom buildpacks, refer to the [buildpacks](#) section of the PCF documentation.
- The **Allow SSH access to app containers** checkbox controls SSH access to application instances. Enable the checkbox to permit SSH access across your deployment, and disable it to prevent all SSH access. See the [Application SSH Overview](#) topic for information about SSH access permissions at the space and app scope.
- If you want to enable SSH access for new apps by default in spaces that allow SSH, select **Enable SSH when an app is created**. If you deselect the checkbox, developers can still enable SSH after pushing their apps by running `cf enable-ssh APP-NAME`.
- If you want to disable the Garden Root filesystem (GrootFS), deselect the **Enable the GrootFS container image plugin for Garden RunC** checkbox. Pivotal recommends using this plugin, so it is enabled by default. However, some external components are sensitive to dependencies with filesystems such as GrootFS. If you experience issues, such as antivirus or firewall compatibility problems, deselect the checkbox to roll back to the plugin that is built into Garden RunC. For more information about GrootFS, see [Component: Garden](#) and [Container Mechanics](#).

 **Note:** If you modify this setting, Pivotal recommends recreating all VMs in the BOSH Director config. You can do this by selecting the **Recreate all VMs** checkbox in the **Director Config** pane of the BOSH Director tile before you redeploy.

- To enable Gorouter to verify app identity using TLS, select the **Router uses TLS to verify application identity** checkbox.

Verifying app identity using TLS enables encryption between router and app containers and guards against misrouting during control plane failures. For more information about Gorouter route consistency modes, see [Preventing Misrouting](#) in *HTTP Routing*.

 **warning:** TLS routing requires an additional 32 MB of RAM capacity on Diego cells per app instance. It also requires additional CPU capacity on Diego cells. If the total amount of Diego cell memory available is less than 32 MB times the number of running app instances, scale your Diego cells before configuring the Gorouter with TLS.

 **Warning:** You may see an increase of memory and CPU usage for your Gorouters after enabling TLS routing. If the total amount of memory and CPU usage of the Gorouters in your environment are close to the size limit, scale your Gorouters before enabling TLS routing.

- You can configure Pivotal Application Service (PAS) to run app instances in Docker containers by supplying their IP address ranges in the **Private Docker Insecure Registry Whitelist** textbox. See the [Using Docker Registries](#) topic for more information.
- Select your preference for **Docker Images Disk-Cleanup Scheduling on Cell VMs**. If you choose **Clean up disk-space once threshold is reached**, enter a **Threshold of Disk-Used** in megabytes. For more information about the configuration options and how to configure a threshold, see [Configuring Docker Images Disk-Cleanup Scheduling](#).
- Enter a number in the **Max Inflight Container Starts** textbox. This number configures the maximum number of started instances across the Diego cells in your deployment. For more information about this feature, see [Setting a Maximum Number of Started Containers](#).
- Under **Enabling NFSv3 volume services**, select **Enable** or **Disable**. NFS volume services allow application developers to bind existing NFS volumes to their applications for shared file access. For more information, see the [Enabling NFS Volume Services](#) topic.

 **Note:** In a clean install, NFSv3 volume services is enabled by default. In an upgrade, NFSv3 volume services is set to the same setting as it was in the previous deployment.

- (Optional) To configure LDAP for NFSv3 volume services, do the following:

Enabling NFSv3 volume services will allow application developers to bind existing NFS volumes to their applications for shared file access. *

☒ Enable

LDAP Service Account User

LDAP Service Account Password

LDAP Server Host

LDAP Server Port

LDAP User Fully-Qualified Domain Name

☐ Disable

Format of timestamps in Diego logs*

☒ RFC3339 timestamps (e.g. 2018-02-09T00:54:13.479724884Z)

☐ Seconds since the Unix epoch (e.g. 1518137653.479724884)

Save

- For **LDAP Service Account User**, enter the username of the service account in LDAP that will manage volume services.
- For **LDAP Service Account Password**, enter the password for the service account.
- For **LDAP Server Host**, enter the hostname or IP address of the LDAP server.
- For **LDAP Server Port**, enter the LDAP server port number. If you do not specify a port number, Ops Manager uses 389.
- For **LDAP User Fully-Qualified Domain Name**, enter the fully qualified path to the LDAP service account. For example, if you have a service account named `volume-services` that belongs to organizational units (OU) named `service-accounts` and `my-company`, and your domain is named `domain`, the fully qualified path looks like the following:

```
CN=volume-services,OU=service-accounts,OU=my-company,DC=domain,DC=com
```

- By default, PAS manages container images using the [GrootFS](#) plugin for Garden-runC. If you experience issues with GrootFS, you can disable the plugin and use the image plugin built into Garden-runC.

13. Select the **Format of timestamps in Diego logs**, either **RFC3339 timestamps** or **Seconds since the Unix epoch**. Fresh PAS v2.2 installations default to **RFC3339 timestamps**, while upgrades to PAS v2.2 from previous versions default to **Seconds since the Unix epoch**.
14. You can optionally modify the **Default health check timeout**. The value configured for this field is the amount of time allowed to elapse between starting up an app and the first healthy response from the app. If the health check does not receive a healthy response within the configured timeout, then the app is declared unhealthy. The default timeout is seconds and the maximum configurable timeout is seconds.
15. Click **Save**.

Step 6: Configure Application Developer Controls

1. Select **Application Developer Controls**.

Configure restrictions and default settings for applications pushed to Application Service.

Maximum File Upload Size (MB) (min: 1024, max: 2048) *

Default App Memory (MB) (min: 64, max: 2048) *

Default App Memory Quota per Org (MB) (min: 10240, max: 102400) *

Maximum Disk Quota per App (MB) (min: 512, max: 20480) *

Default Disk Quota per App (MB) (min: 512, max: 20480) *

Default Service Instances Quota per Org (min: 0, max: 1000) *

Staging Timeout (Seconds) *

☐ Allow Space Developers to manage network policies

☒ Enable Service Discovery for Apps

Save

2. Enter the **Maximum File Upload Size (MB)**. This is the maximum size of an application upload.
3. Enter the **Default App Memory (MB)**. This is the amount of RAM allocated by default to a newly pushed application if no value is specified with the cf CLI.
4. Enter the **Default App Memory Quota per Org**. This is the default memory limit for all applications in an org. The specified limit only applies to the first installation of PAS. After the initial installation, operators can use the cf CLI to change the default value.
5. Enter the **Maximum Disk Quota per App (MB)**. This is the maximum amount of disk allowed per application.

 **Note:** If you allow developers to push large applications, PAS may have trouble placing them on Cells. Additionally, in the event of a system

upgrade or an outage that causes a rolling deploy, larger applications may not successfully re-deploy if there is insufficient disk capacity. Monitor your deployment to ensure your Cells have sufficient disk to run your applications.

6. Enter the **Default Disk Quota per App (MB)**. This is the amount of disk allocated by default to a newly pushed application if no value is specified with the cf CLI.
7. Enter the **Default Service Instances Quota per Org**. The specified limit only applies to the first installation of PAS. After the initial installation, operators can use the cf CLI to change the default value .
8. Enter the **Staging Timeout (Seconds)**. When you stage an application droplet with the Cloud Controller, the server times out after the number of seconds you specify in this field.
9. Select the **Allow Space Developers to manage network policies** checkbox to permit developers to manage their own network policies for their applications.
10. The **Enable Service Discovery for Apps** checkbox, which enables service discovery between applications, is enabled by default. To disable this feature, clear this checkbox. For more information about application service discovery, see the [App Service Discovery](#) section of the *Understanding Container-to-Container Networking* topic.
11. Click **Save**.

Step 7: Review Application Security Groups

Setting appropriate [Application Security Groups](#) is critical for a secure deployment. Type in the box to acknowledge that once the Pivotal Application Service (PAS) deployment completes, you will review and set the appropriate application security groups. See [Restricting App Access to Internal PCF Components](#) for instructions.

Setting appropriate Application Security Groups that control application network policy is the responsibility of the Elastic Runtime administration team. Please refer to the Application Security Groups topic in the Pivotal Cloud Foundry documentation for more detail on completing this activity after the Elastic Runtime deployment completes.

Type X to acknowledge that you understand this message *

Save

Step 8: Configure UAA

1. Select **UAA**.
2. (Optional) Under **JWT Issuer URI**, enter the URI that UAA uses as the issuer when generating tokens.

JWT Issuer URI

3. Under **SAML Service Provider Credentials**, enter a certificate and private key to be used by UAA as a SAML Service Provider for signing outgoing SAML authentication requests. You can provide an existing certificate and private key from your trusted Certificate Authority or generate a self-signed certificate. The following domain must be associated with the certificate: `*.login.YOUR-SYSTEM-DOMAIN` .

Note: The Pivotal Single Sign-On Service and Pivotal Spring Cloud Services tiles require the `*.login.YOUR-SYSTEM-DOMAIN` .

4. If the private key specified under **Service Provider Credentials** is password-protected, enter the password under **SAML Service Provider Key**

SAML Service Provider Credentials *

-----BEGIN CERTIFICATE-----

Save

Interface (cf CLI) login access and refresh. Most deployments use the defaults.

7. (Optional) In the **Global Login Session Max Timeout** and **Global Login Session Idle Timeout** fields, change the maximum number of seconds before a global login times out. These fields apply to the following:
 - **Default zone sessions:** Sessions in Apps Manager, PCF Metrics, and other web UIs that use the UAA default zones
 - **Identity zone sessions:** Sessions in apps that use a UAA identity zone, such as a Single Sign-On service plan

8. (Optional) Customize the text prompts used for username and password from the cf CLI and Apps Manager login popup by entering values for **Customize Username Label (on login page)** and **Customize Password Label (on login page)**.
9. (Optional) The **Proxy IPs Regular Expression** field contains a pipe-delimited set of regular expressions that UAA considers to be reverse proxy IP addresses. UAA respects the `x-forwarded-for` and `x-forwarded-proto` headers coming from IP addresses that match these regular expressions. To configure UAA to respond properly to Gorouter or HAProxy requests coming from a public IP address, append a regular expression or regular expressions to match the public IP address.
10. You can configure UAA to use an internal MySQL database provided with PCF, or you can configure an external database provider. Follow the procedures in either the [Internal Database Configuration](#) or the [External Database Configuration](#) section below.

 **Note:** If you are performing an upgrade, do not modify your existing internal database configuration or you may lose data. You must migrate your existing data before changing the configuration. See [Upgrading Pivotal Cloud Foundry](#) for additional upgrade information, and contact [Pivotal Support](#) for help.

Internal Database Configuration

When you configure the UAA to use an internal MySQL database, it uses the type of database selected in the **Databases** pane, which can be one of two options. See [Migrate to Internal Percona MySQL](#) for details.

1. Select **Internal MySQL**.

Choose the location of your UAA database *

☒ Internal MySQL (preferred for complete high-availability)

☐ External (preferred if, for example, you use AWS RDS)

1. Click **Save**.
2. Ensure that you complete the [Configure Internal MySQL](#) step later in this topic to configure high availability for your internal MySQL databases.

External Database Configuration

 **Note:** The exact procedure to create databases depends upon the database provider you select for your deployment. The following procedure uses AWS RDS as an example, but UAA also supports Azure SQL Server.

 **warning:** Protect whichever database you use in your deployment with a password.

To create your UAA database, perform the following steps:

1. Add the `ubuntu` account key pair from your IaaS deployment to your local SSH profile so you can access the Ops Manager VM. This is the value of the `ops_manager_ssh_private_key` from the Terraform output.

```
$ ssh-add aws-keypair.pem
```

2. SSH in to your Ops Manager using the Ops Manager FQDN and the username `ubuntu`:

```
$ ssh ubuntu@OPS-MANAGER-FQDN
```

3. Log in to your MySQL database instance using the appropriate hostname and user login values configured in your IaaS account. For example, to log in to your AWS RDS instance, run the following MySQL command:

```
$ mysql --host=RDSHOSTNAME --user=RDSUSERNAME --password=RDSPASSWORD
```

4. Run the following MySQL commands to create a database for UAA:

```
CREATE database uaa;
```

5. Type `exit` to quit the MySQL client, and `exit` again to close your connection to the Ops Manager VM.
6. Reboot the RDS instance in the AWS console.
7. From the **UAA** section in Pivotal Application Service (PAS), select **External**.

Choose the location of your UAA database *

☐ Internal MySQL (preferred for complete high-availability)
 ☒ External (preferred if, for example, you use AWS RDS)

Hostname *

TCP Port *

Username *

Password *

8. For **Hostname**, enter the hostname of the database server. This is the value from the `rds_address` key in the Terraform output.
9. For **TCP Port**, enter the port of the database server. This is the value from the `rds_port` key in the Terraform output.
10. For **User Account and Authentication database username**, specify the username that can access this database on the database server. This is the value from the `rds_username` key in the Terraform output.
11. For **User Account and Authentication database password**, specify a password for the provided username. This is the value from the `rds_password` key in the Terraform output.
12. Click **Save**.

Step 9: Configure CredHub

Note: Enabling CredHub is not required. However, you cannot leave the fields under **Encryption Keys** blank. If you do not intend to use CredHub, enter any text in the **Name** and **Key** fields as placeholder values.

1. Select **CredHub**.
2. Choose the location of your CredHub database. PAS includes this CredHub database for services to store their service instance credentials.

Note: You cannot choose **Internal** for the CredHub database if you choose **External** for your System Databases. See [Configure System Databases](#) below.

Configure the CredHub Server

Choose the location of your CredHub database *

☒ Internal MySQL (preferred for complete high-availability)
 ☐ External (preferred if, for example, you use Google Cloud SQL)

If you chose **External**, enter the following:

- **Hostname.** This is the IP address of your database server. See the value from the `PcfRdsAddress` key in the AWS output.
- **TCP Port.** This is the port of your database server. See the value from the `PcfRdsPort` key in the AWS output.
- **Username.** This is the value from the `PcfRdsUsername` key in the AWS output.
- **Password.** This is the value from the `PcfRdsPassword` key in the AWS output.
- **Database CA Certificate.** This certificate is used when encrypting traffic to and from the database.

3. Under **Encryption Keys**, specify one or more keys to use for encrypting and decrypting the values stored in the CredHub database.

Encryption Keys

Name *

Name of the encryption key.

Provider*

Internal

Key *

Secret

☐ Primary

- **Name.** This is the name of the encryption key.
 - If you plan to use internal encryption, enter any key name.
 - If you plan to use an HSM as your encryption provider, enter a key name that already exists on your HSM or a new key name. For each new key name, CredHub generates a key in **HSM Provider Partition** that you configure below.
- **Provider.** This is the provider of the encryption key. If you plan to configure an HSM provider and HSM servers below, select **HSM**. Otherwise, select **Internal**.
- **Key.** If you select internal encryption, this key is used for encrypting all data. The key must be at least 20 characters long.
 - If you selected **Internal** above, enter a randomly generated value under **Key**.
 - If you selected **HSM** above, enter a placeholder value under **Key**. CredHub does not use this key for encryption. However, you cannot leave the **Key** field blank.
- **Primary.** This checkbox is used for marking the key you specified above as the primary encryption key. You must mark one key as **Primary**. Do not mark more than one key as **Primary**.

 **Note:** For information about using additional keys for key rotation, see the [Rotating Runtime CredHub Encryption Keys](#) topic.

4. (Optional) To configure CredHub to use an HSM, complete the following fields:

- **HSM Provider Partition.** This is the name of the HSM provider partition.
- **HSM Provider Partition Password.** This password is used to access the HSM provider partition.
- **HSM Provider Client Certificate.** This is the client certificate for the HSM. For more information, see [Create and Register HSM Clients](#) in the

Preparing CredHub HSMs for Configuration topic.

- In the **HSM Provider Servers** section, click **Add** to add an HSM server. You can add multiple HSM servers. For each HSM server, complete the following fields:
 - **Host Address.** This is the host name or IP address of the HSM server.
 - **Port.** This is the port of the HSM server. If you do not know your port address, enter `1792`.
 - **Partition Serial Number.** This is the serial number of the HSM partition.
 - **HSM Certificate.** This is the certificate for the HSM server. The HSM presents this certificate to CredHub to establish a two-way TLS connection.

5. If your deployment uses any PCF services that support storing service instance credentials in CredHub and you want to enable this feature, select the **Secure Service Instance Credentials** checkbox.
6. Click **Save**.
7. Select the **Resource Config** pane.
8. Under the **Job** column of the **CredHub** row, set the number of instances to `2`. This is the minimum instance count required for high availability.
9. Click **Save**.

For more information about using CredHub for securing service instance credentials, see [Securing Service Instance Credentials with Runtime CredHub](#).

Step 10: Configure Authentication and Enterprise SSO

1. Select **Authentication and Enterprise SSO**.

Configure your user store access, which can be an internal user store (managed by Cloud Foundry's UAA) or an external user store (LDAP or SAML). You can also adjust the lifetimes of authentication tokens.

Configure your UAA user account store with either internal or external authentication mechanisms *

☒ Internal UAA (provided by Elastic Runtime; configure your password policy below)

Minimum Password Length *

Minimum Uppercase Characters Required for Password *

Minimum Lowercase Characters Required for Password *

Minimum Numerical Digits Required for Password *

Minimum Special Characters Required for Password *

Maximum Password Entry Attempts Allowed *

2. To authenticate user sign-ons, your deployment can use one of three types of user database: the UAA server's internal user store, an external SAML identity provider, or an external LDAP server.

- To use the internal UAA, select the **Internal** option and follow the instructions in the [Configuring UAA Password Policy](#) topic to configure your password policy.
- To connect to an external identity provider through SAML, scroll down to select the **SAML Identity Provider** option and follow the instructions in the [Configuring PCF for SAML](#) section of the *Configuring Authentication and Enterprise SSO for Pivotal Application Service (PAS)* topic.
- To connect to an external LDAP server, scroll down to select the **LDAP Server** option and follow the instructions in the [Configuring LDAP](#) section of the *Configuring Authentication and Enterprise SSO for PAS* topic.

3. Click **Save**.

Step 11: Configure System Databases

You can configure PAS to use an internal MySQL database provided with PCF, or you can configure an external database provider for the databases required by PAS.

 **Note:** If you are performing an upgrade, do not modify your existing internal database configuration or you may lose data. You must migrate your existing data first before changing the configuration. See [Upgrading Pivotal Cloud Foundry](#) for additional upgrade information.

Internal Database Configuration

If you want to use internal databases for your deployment, perform the following steps:

1. Select **Databases**.
2. Select one of the **Internal Databases** options:

- Internal Databases - MySQL - Percona XtraDB Cluster uses [Percona Server](#) with TLS encryption between server cluster nodes.
- Internal Databases - MySQL - MariaDB Galera Cluster uses [MariaDB](#) with cluster nodes communicating over plaintext.

⚠ warning: Changing existing internal databases from **MySQL - MariaDB Galera Cluster** to **MySQL - Percona XtraDB Cluster** migrates the databases after you click **Apply Changes**, causing temporary system downtime. See [Migrate to Internal Percona MySQL](#) for details.

Choose the location of your system databases. Please consult the documentation for migrating existing installations from MariaDB to Percona. *

- ☒ Internal Databases - MySQL - Percona XtraDB Cluster
- ☐ Internal Databases - MySQL - MariaDB Galera Cluster (deprecated - planned to be removed in PAS 2.4)
- ☐ External Databases - (e.g. AWS RDS)

Save

3. Click **Save**.

Then proceed to [Step 13: \(Optional\) Configure Internal MySQL](#) to configure high availability for your internal MySQL databases.

Create External System Databases

If you want to use an external database provider for your PAS databases, you must first create the databases on the RDS instance provided by the Terraform templates.

To create the required databases on an AWS RDS instance, perform the following steps.

1. Add the AWS-provided key pair to your SSH profile so that you can access the Ops Manager VM. This is the value of the `ops_manager_ssh_private_key` from the Terraform output.

```
ssh-add aws-keypair.pem
```

2. SSH in to your Ops Manager using the Ops Manager FQDN and the username `ubuntu`:

```
ssh ubuntu@OPS_MANAGER_FQDN
```

3. Run the following terminal command to log in to your RDS instance through the MySQL client, using values from the terraform output to fill in the following keys:

```
mysql --host=rds_address --user=rds_username --password=rds_password
```

4. Run the following MySQL commands to create databases for the seven PAS components that require a relational database:

```
CREATE database ccdb;
CREATE database notifications;
CREATE database autoscale;
CREATE database app_usage_service;
CREATE database routing;
CREATE database diego;
CREATE database account;
CREATE database nfsvolume;
CREATE database networkpolicyserver;
CREATE database silk;
CREATE database locket;
CREATE database credhub;
```

5. Type `exit` to quit the MySQL client, and `exit` again to close your connection to the Ops Manager VM.
6. Reboot the RDS instance in the AWS console.
7. In PAS, select **Databases**.
8. Select the **External Databases** option.

Place the databases used by Application Service components.

Choose the location of your system databases. Please consult the documentation for migrating existing installations from MariaDB to Percona. *

- ☐ Internal Databases - MySQL - Percona XtraDB Cluster
- ☐ Internal Databases - MySQL - MariaDB Galera Cluster (deprecated - planned to be removed in PAS 2.4)
- ☒ External Databases - (e.g. AWS RDS)

Hostname *

TCP Port *

App Usage Service Database Username *

App Usage Service Database Password *

9. For the **Hostname** and **TCP Port** fields, complete the following fields:

| PAS Field | terraform output |
|-----------|--------------------------|
| Hostname | <code>rds_address</code> |
| TCP Port | <code>rds_port</code> |

10. For each **database username** and **database password** field, complete the following fields:

| PAS Field | terraform output |
|---------------------------------|---------------------------|
| DATABASE-NAME database username | <code>rds_username</code> |
| DATABASE-NAME database password | <code>rds_password</code> |

 **Note:** Ensure that the networkpolicyserver database user has the `ALL PRIVILEGES` permission.

1. Click **Save**.

Step 13: (Optional) Configure Internal MySQL

 **Note:** You only need to configure this section if you have selected one of the **Internal Databases - MySQL** options in the **Databases** section.

To use internal MySQL in High Availability configuration, you define a load balancer rule that lets PAS components send queries a single hostname backed by two redundant proxies. Each proxy then directs query traffic to three MySQL server nodes.

1. Allocate an internal load balancer rule to balance traffic between two static IP addresses. The static IP addresses cannot be within the range that that you have reserved for PAS.
The load balancer rule is separate from the software provided by Pivotal, and you need to define it within your infrastructure.
 - **Make your idle time out long enough to not interrupt long-running queries.** When queries take a long time, the load balancer can time out and interrupt the query.
For example, [AWS's Elastic Load Balancer](#) has a default idle timeout of 60 seconds, so queries that take longer than this duration sever the MySQL connection and return an error.
 - **Configure a healthcheck or monitor, using TCP against port 1936.** This defaults to TCP port `1936`, to maintain backwards compatibility with previous releases. This port is not configurable. Unauthenticated healthchecks against port 3306 may cause the service to become unavailable and require manual intervention to fix.
 - **Configure the load balancer to route traffic for TCP port 3306 to the IPs of all proxy instances on TCP port 3306.**

- Record the hostname of the load balancer rule and the two static IP addresses.

 **warning:** You must configure a load balancer to achieve complete high availability.

- From the PAS tile in Ops Manager, Select **Internal MySQL**.
- In the **MySQL Proxy IPs** field, enter the static IP addresses used by the internal MySQL load balancer rule.

Only configure this section if you selected Internal Databases - MySQL in the previous Databases section.

A proxy tier routes MySQL connections from internal components to healthy cluster nodes. Configure DNS and/or your own load balancer to point to multiple proxy instances for increased availability. TCP healthchecks can be configured against port 1936.

The automated backups functionality works with any S3-compatible file store that can receive your backup files.

MySQL Proxy IPs

MySQL Service Hostname

- For **MySQL Service Hostname**, enter the IP address or hostname for your load balancer. If you leave this field blank, components are configured with the IP address of the first proxy instance entered above.
- In the **Replication canary time period** field, leave the default of 30 seconds or modify the value based on the needs of your deployment. Lower numbers cause the canary to run more frequently, which means that the canary reacts more quickly to replication failure but adds load to the database.
- In the **Replication canary read delay** field, leave the default of 20 seconds or modify the value based on the needs of your deployment. This field configures how long the canary waits, in seconds, before verifying that data is replicating across each MySQL node. Clusters under heavy load can experience a small replication lag as write-sets are committed across the nodes.
- (**Required**): In the **E-mail address** field, enter the email address where the MySQL service sends alerts when the cluster experiences a replication issue or when a node is not allowed to auto-rejoin the cluster.
- To prohibit the creation of command line history files on the MySQL nodes, disable the **Allow Command History** checkbox.
- To allow the admin and roadmin to connect from any remote host, enable the **Allow Remote Admin Access** checkbox. When the checkbox is disabled, admins must `bosh ssh` into each MySQL VM to connect as the MySQL super user.

 **Note:** Network configuration and Application Security Groups restrictions may still limit a client's ability to establish a connection with the databases.

- For **Cluster Probe Timeout**, enter the maximum amount of time, in seconds, that a new node will search for existing cluster nodes. If left blank, the default value is 10 seconds.

Replication canary time period *

Replication canary read delay *

E-mail address (required) *

☒ Allow Command History

Cluster Probe Timeout

11. For **Max Connections**, enter the maximum number of connections allowed to the database. If left blank, the default value is 1500.
12. If you want to log audit events for internal MySQL, select **Enable server activity logging** under **Server Activity Logging**.
 - a. For the **Event types** field, you can enter the events you want the MySQL service to log. By default, this field includes `connect` and `query`, which tracks who connects to the system and what queries are processed.

Server Activity Logging *

☐ Disable server activity logging

☒ Enable server activity logging

Event types *

Load Balancer Healthy Threshold *

Load Balancer Unhealthy Threshold *

Save

13. Enter values for the following fields:
 - **Load Balancer Healthy Threshold:** Specifies the amount of time, in seconds, to wait until declaring the MySQL Proxy instance started. This allows an external load balancer time to register the instance as healthy.
 - **Load Balancer Unhealthy Threshold:** Specifies the amount of time, in seconds, that the MySQL Proxy continues to accept connections before shutting down. During this period, the Healthcheck reports as unhealthy to cause load balancers to fail over to other proxies. You must enter a value greater than or equal to the maximum time it takes your load balancer to consider a proxy instance unhealthy, given repeated failed healthchecks.
14. If you want to enable the MySQL interruptor feature, select the checkbox to **Prevent node auto re-join**. This feature stops all writes to the MySQL database if it notices an inconsistency in the dataset between the nodes. For more information, see the [Interruptor](#) section in the MySQL for PCF documentation.
15. Click **Save**.

For more information on how to monitor the node health of your MySQL Proxy instances, see [Using the MySQL Proxy](#).

Step 14: Configure File Storage

To minimize system downtime, Pivotal recommends using highly resilient and redundant *external* filestores for your Pivotal Application Service (PAS) file storage.

When configuring file storage for the Cloud Controller in PAS, you can select one of the following:

- Internal WebDAV filestore
- External S3-compatible or Ceph-compatible filestore
- External Google Cloud Storage with Access Key and Secret Key
- External Google Cloud Storage with Service Account
- External Azure Cloud Storage

For production-level PCF deployments on AWS, Pivotal recommends selecting the **External S3-Compatible File Store**. For more information about production-level PCF deployments on AWS, see the [Reference Architecture for Pivotal Cloud Foundry on AWS](#).

For additional factors to consider when selecting file storage, see the [Considerations for Selecting File Storage in Pivotal Cloud Foundry](#) topic.

Internal Filestore

Internal file storage is only appropriate for small, non-production deployments.

To use the PCF internal filestore, perform the following steps:

1. In the Pivotal Application Service (PAS) tile, select **File Storage**.
2. Select **Internal WebDAV**, and click **Save**.

External S3 or Ceph Filestore

To use an external S3-compatible filestore for PAS file storage, perform the following steps:

1. In the PAS tile, select **File Storage**.
2. Select the **External S3-Compatible Filestore** option and complete the following fields:
 - Enter the `https://` **URL Endpoint** for your region.
For example, in the **us-west-2** region, enter `https://s3-us-west-2.amazonaws.com/`.
 - If you use an AWS instance profile to manage role information for your filestore, select the **S3 AWS with Instance Profile** checkbox. For more information, see [AWS Identity and Access Management](#) in the AWS documentation.

- Alternatively, enter the **Access Key** and **Secret Key** of the `pcf-user` you created when configuring AWS for PCF. If you select the **S3 AWS with Instance Profile** checkbox and also enter an **Access Key** and **Secret Key**, the instance profile will overrule the Access Key and Secret Key.
- From the **S3 Signature Version** dropdown, select **V4 Signature**. For more information about S4 signatures, see [Signing AWS API Requests](#) in the AWS documentation.
- For **Region**, enter the region in which your S3 buckets are located. `us-west-2` is an example of an acceptable value for this field.
- Select **Server-side Encryption** to encrypt the contents of your S3 filestore. This option is only available for AWS S3.
- (Optional) If you selected **Server-side Encryption**, you can also specify a **KMS Key ID**. PAS uses the KMS key to encrypt files uploaded to the

blobstore. If you do not provide a KMS Key ID, PAS uses the default AWS key. For more information, see [Protecting Data Using Server-Side Encryption with AWS KMS–Managed Keys \(SSE-KMS\)](#).

- Enter names for your S3 buckets:

| Ops Manager Field | Value | Description |
|------------------------|-----------------------|---|
| Buildpacks Bucket Name | pcf-buildpacks-bucket | This S3 bucket stores app buildpacks. |
| Droplets Bucket Name | pcf-droplets-bucket | This S3 bucket stores app droplets. Pivotal recommends that you use a unique bucket name for droplets, but you can also use the same name as above. |
| Packages Bucket Name | pcf-packages-bucket | This S3 bucket stores app packages. Pivotal recommends that you use a unique bucket name for packages, but you can also use the same name as above. |
| Resources Bucket Name | pcf-resources-bucket | This S3 bucket stores app resources. Pivotal recommends that you use a unique bucket name for app resources, but you can also use the same name as above. |

- Configure the following depending on whether your S3 buckets have versioning enabled:
 - Versioned S3 buckets:** Enable the **Use versioning for backup and restore** checkbox to archive each bucket to a version.
 - Unversioned S3 buckets:** Disable the **Use versioning for backup and restore** checkbox, and enter a backup bucket name for each active bucket. The backup bucket name must be different from the name of the active bucket it backs up.

☐ Use versioning for backup and restore.
 (All of the above buckets must have versioning enabled and use the V4 S3 Signature Version).

If versioning is not enabled or supported, you can configure separate buckets below for backups. More information at <https://docs.pivotal.io/pivotalcf/2-1/customizing/backup-restore/backup-pcf-bbr.html>.

Backup Region

Backup Buildpacks Bucket Name

Backup Droplets Bucket Name

Backup Packages Bucket Name

For more information

about setting up external S3 blobstores, see the [Backup and Restore with External Blobstores](#) topic in the Cloud Foundry documentation.

- Click **Save**.

 **Note:** For more information regarding AWS S3 Signatures, see the [Authenticating Requests](#) topic in the AWS documentation.

Other IaaS Storage Options

[Google Cloud Storage](#) and [Azure Storage](#) are also available as file storage options, but are not recommended for typical PCF on AWS installations.

Step 15: (Optional) Configure System Logging

You can configure system logging in PAS to forward log messages from PAS component VMs to an external service. Pivotal recommends forwarding logs to an external service for use in troubleshooting.

 **Note:** The following instructions explain how to configure system logging for PAS component VMs. To forward logs from PCF tiles to an external service, you must also configure system logging in each tile. See the documentation for the given tiles for information about configuring system

logging.

To configure system logging in PAS, do the following:

1. In the PAS **Settings** tab, select the **System Logging** pane. The following image shows the **System Logging** pane.

Optionally configure rsyslog to forward platform component logs to an external service. If you do not fill these fields, platform logs will not be forwarded but will remain available on the component VMs and for download via Ops Manager.

Address

Port

Transport Protocol

Encrypt syslog using TLS?*

☒ No

☐ Yes

Syslog Drain Buffer Size (# of messages) *

☒ Include container metrics in SysLog Drains

☒ Enable Cloud Controller security event logging

☐ Use TCP for file forwarding local transport

☒ Don't Forward Debug Logs

Custom rsyslog Configuration

Save

2. For **Address**, enter the IP address of the syslog server.
3. For **Port**, enter the port of the syslog server. The default port for a syslog server is `514`.

 **Note:** The host must be reachable from the PAS network and accept UDP or TCP connections. Ensure the syslog server listens on external interfaces.

4. For **Transport Protocol**, select a transport protocol for log forwarding.
5. For **Encrypt syslog using TLS?**, select **Yes** to use TLS encryption when forwarding logs to a remote server.
 - a. For **Permitted Peer**, enter either the name or SHA1 fingerprint of the remote peer.
 - b. For **TLS CA Certificate**, enter the TLS CA certificate for the remote server.

6. For **Syslog Drain Buffer Size**, enter the number of messages from the Loggregator Agent that the Doppler server can store before it begins to drop messages. See the [Loggregator Guide for Cloud Foundry Operators](#) topic for more details.
7. Disable the **Include container metrics in Syslog Drains** checkbox to prevent the [CF Drain CLI plugin](#) from including app container metrics in syslog drains. This feature is enabled by default.
8. Enable the **Enable Cloud Controller security event logging** checkbox to include security events in the log stream. This feature logs all API requests, including the endpoint, user, source IP address, and request result, in the Common Event Format (CEF).
9. Enable the **Use TCP for file forwarding local transport** checkbox to transmit logs over TCP. This prevents log truncation, but may cause performance issues.
10. Disable the **Don't Forward Debug Logs** checkbox to forward DEBUG syslog messages to an external service. This checkbox is enabled by default.

 **Note:** Some PAS components generate a high volume of DEBUG syslog messages. Enabling the **Don't Forward Debug Logs** checkbox prevents PAS components from forwarding the DEBUG syslog messages to external services. However, PAS still writes the messages to the local disk.

11. For **Custom rsyslog Configuration**, enter a custom syslog rule. For more information about adding custom syslog rules, see [Customizing Syslog Rules](#).
12. Click **Save**.

To configure Ops Manager for system logging, see the [Settings](#) section in the *Using the Ops Manager Interface* topic.

Step 16: (Optional) Customize Apps

This section describes how to configure **Custom Branding** and **Apps Manager** to customize the appearance and functionality of Apps Manager. For more information about the **Custom Branding** configuration settings, see [Custom Branding Apps Manager](#).

1. Select **Custom Branding**. Use this section to configure the text, colors, and images of the interface that developers see when they log in, create an account, reset their password, or use Apps Manager.

Customize colors, images, and text for Apps Manager and the Cloud Foundry login portal.

Company Name

3. Select **Apps Manager**.

Configure Apps Manager

☒ Enable Invitations

☐ Display Marketplace Service Plan Prices

Supported currencies as JSON *

```
{ "usd": "$", "eur": "€" }
```

Product Name

Marketplace Name

Customize Sidebar Links Add

You may configure up to 10 links in the Apps Manager sidebar.

- ▶ Marketplace 🗑️
- ▶ Docs 🗑️
- ▶ Tools 🗑️

Apps Manager Memory Usage (MB) (min: 128)

Invitations Memory Usage (MB) (min: 256)

Apps Manager Polling Interval *

30

Apps manager polling interval in seconds. As a workaround to reduce load on the Cloud Controller API, increase the polling interval or set to 0 to stop polling. Values between 0 and 30 will default to 30 seconds.

Save

4. Select **Enable Invitations** to enable invitations in Apps Manager. Space Managers can invite new users for a given space, Org Managers can invite new users for a given org, and Admins can invite new users across all orgs and spaces. See the [Inviting New Users](#) section of the *Managing User Roles with Apps Manager* topic for more information.
5. Select **Display Marketplace Service Plan Prices** to display the prices for your services plans in the Marketplace.
6. Enter the **Supported currencies as JSON** to appear in the Marketplace. Use the format `{ "CURRENCY-CODE": "SYMBOL" }`. This defaults to `{ "usd": "$", "eur": "€" }`.
7. Use **Product Name**, **Marketplace Name**, and **Customize Sidebar Links** to configure page names and sidebar links in the **Apps Manager** and **Marketplace** pages.
8. The **Apps Manager Memory Usage (MB)** field sets the memory limit with which to deploy the Apps Manager app. Use this field to increase the memory limit if the app fails to start with an `out of memory` error.
9. The **Invitations Memory Usage (MB)** field sets the memory limit with which to deploy the Invitations app. Use this field to increase the memory limit if the app fails to start with an `out of memory` error.

10. The **Apps Manager Polling Interval** field provides a temporary fix if Apps Manager usage degrades Cloud Controller response times. In this case, you can use this field to reduce the load on the Cloud Controller and ensure Apps Manager remains available while you troubleshoot the Cloud Controller. Pivotal recommends that you do not keep this field modified as a long term fix because it can degrade Apps Manager performance. You can optionally do the following:

- Increase the polling interval above the default of `30` seconds.

 **Note:** If you enter a value between `0` and `30`, the field is automatically set to `30`.

- Disable polling by entering `0`. This stops Apps Manager from refreshing data automatically, but users can update displayed data by reloading Apps Manager manually.

11. Click **Save** to save your settings in this section.

Step 17: (Optional) Configure Email Notifications

PAS uses SMTP to send invitations and confirmations to Apps Manager users. You must complete the **Email Notifications** page if you want to enable end-user self-registration.

1. Select **Email Notifications**.

Configure Simple Mail Transfer Protocol for the Notifications application to send email notifications about your deployment. This application is deployed as an errand in Elastic Runtime. If you do not need this service, leave this section blank and disable the Notifications and Notifications UI errands.

From Email

Address of SMTP Server

Port of SMTP Server

SMTP Server Credentials

[Change](#)

☒ SMTP Enable Automatic STARTTLS

SMTP Authentication Mechanism*

SMTP CRAMMD5 secret

2. Enter your reply-to and SMTP email information.

 **Note:** For GCP, you must use port `2525`. Ports `25` and `587` are not allowed on GCP Compute Engine.

3. Verify your authentication requirements with your email administrator and use the **SMTP Authentication Mechanism** dropdown to select `None`, `Plain`, or `CRAMMD5`. If you have no SMTP authentication requirements, select `None`.

- If you selected `CRAMMD5` as your authentication mechanism, enter a secret in the **SMTP CRAMMD5 secret** field.
- Click **Save**.

Note: If you do not configure the SMTP settings using this form, the administrator must create orgs and users using the cf CLI. See [Creating and Managing Users with the cf CLI](#) for more information.

Step 18: (Optional) Configure App Autoscaler

To use App Autoscaler, you must create an instance of the service and bind it to an app. To create an instance of App Autoscaler and bind it to an app, see [Set Up App Autoscaler](#) in the *Scaling an Application Using App Autoscaler* topic.

- Click **App Autoscaler**.

Configure the App Autoscaler

Autoscaler Instance Count (min: 1) *

Autoscaler API Instance Count (min: 1) *

Metric Collection Interval (min: 60, max: 3600) (min: 60, max: 3600) *

Scaling Interval (min: 15, max: 120) (min: 15, max: 120) *

☐ Verbose Logging

☐ Disable API Connection Pooling

☒ Enable Notifications

- Review the following settings:

- Autoscaler Instance Count:** How many instances of the App Autoscaler service you want to deploy. The default value is `3`. For high availability, set this number to `3` or higher. You should set the instance count to an odd number to avoid split-brain scenarios during leadership elections. Larger environments may require more instances than the default number.
- Autoscaler API Instance Count:** How many instances of the App Autoscaler API you want to deploy. The default value is `1`. Larger environments may require more instances than the default number.
- Metric Collection Interval:** How many seconds of data collection you want App Autoscaler to evaluate when making scaling decisions. The minimum interval is 60 seconds, and the maximum interval is 3600 seconds. The default value is `120`. Increase this number if the metrics you use in your scaling rules are emitted less frequently than the existing Metric Collection Interval.
- Scaling Interval:** How frequently App Autoscaler evaluates an app for scaling. The minimum interval is 15 seconds, and the maximum interval is 120 seconds. The default value is `35`.
- Verbose Logging** (checkbox): Enables verbose logging for App Autoscaler. Verbose logging is disabled by default. Select this checkbox to see more detailed logs. Verbose logs show specific reasons why App Autoscaler scaled the app, including information about minimum and maximum instance limits, App Autoscaler's status. For more information about App Autoscaler logs, see [App Autoscaler Events and Notifications](#).
- Disable API Connection Pooling:** API connection pooling increases performance by reducing the cost associated with establishing new connections. If you do not want to keep connections open for reuse, select this option.

3. Click **Save**.

Step 19: Configure Cloud Controller

1. Click **Cloud Controller**.

Configure the Cloud Controller

Cloud Controller DB Encryption Key

Secret

Enabling CF API Rate Limiting will prevent API consumers from overwhelming the platform API servers. Limits are imposed on a per-user or per-client basis and reset on an hourly interval. *

☐ Enable
 ☒ Disable

Save

2. Enter your **Cloud Controller DB Encryption Key** if all of the following are true:

- You deployed Pivotal Application Service (PAS) previously.
- You then stopped PAS or it crashed.
- You are re-deploying PAS with a backup of your Cloud Controller database.

See [Backing Up Pivotal Cloud Foundry](#) for more information.

3. CF API Rate Limiting prevents API consumers from overwhelming the platform API servers. Limits are imposed on a per-user or per-client basis and reset on an hourly interval.

To disable CF API Rate Limiting, select **Disable** under **Enable CF API Rate Limiting**. To enable CF API Rate Limiting, perform the following steps:

- Under **Enable CF API Rate Limiting**, select **Enable**.
- For **General Limit**, enter the number of requests a user or client is allowed to make over an hour interval for all endpoints that do not have a custom limit. The default value is `2000`.
- For **Unauthenticated Limit**, enter the number of requests an unauthenticated client is allowed to make over an hour interval. The default value is `100`.

4. Click **Save**.

Step 20: Configure Smoke Tests

The Smoke Tests errand runs basic functionality tests against your Pivotal Application Service (PAS) deployment after an installation or update. In this section, choose where to run smoke tests. In the **Errands** section, you can choose whether or not to run the Smoke Tests errand.

1. Select **Smoke Tests**.
2. If you have a shared apps domain, select **Temporary space within the system organization**, which creates a temporary space within the `system` organization for running smoke tests and deletes the space afterwards. Otherwise, select **Specified org and space** and complete the fields to specify where you want to run smoke tests.

Specify a Cloud Foundry organization and space where smoke tests can run if in the future you delete your Elastic Runtime deployment domains.

Choose where to deploy applications when running the smoke tests *

- ☐ Temporary space within the system organization (This is deleted after smoke tests finish.)
- ☒ Specified org and space (The org and space must have a domain available for routing.)

Organization *

Space *

Domain *

Save

3. Click **Save**.

Step 21: (Optional) Enable Advanced Features

The **Advanced Features** section of Pivotal Application Service (PAS) includes new functionality that may have certain constraints. Although these features are fully supported, Pivotal recommends caution when using them in production environments.

Diego Cell Memory and Disk Overcommit

If your apps do not use the full allocation of disk space and memory set in the **Resource Config** tab, you might want use this feature. These fields control the amount to overcommit disk and memory resources to each Diego Cell VM.

For example, you might want to use the overcommit if your apps use a small amount of disk and memory capacity compared to the amounts set in the **Resource Config** settings for **Diego Cell**.

Note: Due to the risk of app failure and the deployment-specific nature of disk and memory use, Pivotal has no recommendation about how much, if any, memory or disk space to overcommit.

To enable overcommit, do the following:

1. Select **Advanced Features**.

Cell Memory Capacity (MB) (min: 1)

Cell Disk Capacity (MB) (min: 1)

2. Enter the total desired amount of Diego cell memory value in the **Cell Memory Capacity (MB)** field. Refer to the **Diego Cell** row in the **Resource Config** tab for the current Cell memory capacity settings that this field overrides.
3. Enter the total desired amount of Diego cell disk capacity value in the **Cell Disk Capacity (MB)** field. Refer to the **Diego Cell** row in the **Resource Config** tab for the current Cell disk capacity settings that this field overrides.
4. Click **Save**.

 **Note:** Entries made to each of these two fields set the total amount of resources allocated, not the overage.

Whitelist for Non-RFC-1918 Private Networks

Some private networks require extra configuration so that internal file storage (WebDAV) can communicate with other PCF processes.

The **Whitelist for non-RFC-1918 Private Networks** field is provided for deployments that use a non-RFC 1918 private network. This is typically a private network other than `10.0.0.0/8`, `172.16.0.0/12`, or `192.168.0.0/16`.

Most PCF deployments do not require any modifications to this field.

To add your private network to the whitelist, do the following:

1. Select **Advanced Features**.
2. Append a new `allow` rule to the existing contents of the **Whitelist for non-RFC-1918 Private Networks** field.

Whitelist for non-RFC-1918 Private Networks *

allow 10.0.0.0/8;;allow 172.16.0.0/12;;allow .

If your Elastic Runtime deployment is using a private network that is not RFC 1918 (10.0.0.0/8, 172.16.0.0/12, 192.168.0.0/16), then you must type in "allow <your-network>;" here. It is important to include the word "allow" and the semi-colon at the end. For example, "allow 172.99.0.0/24;"

Include the word `allow`, the network CIDR range to allow, and a semi-colon (`;`) at the end. For example: `allow 172.99.0.0/24;`

3. Click **Save**.

CF CLI Connection Timeout

The **CF CLI Connection Timeout** field allows you to override the default five second timeout of the Cloud Foundry Command Line Interface (cf CLI) used within your PCF deployment. This timeout affects the cf CLI command used to push PAS errand apps such as Notifications, Autoscaler, and Apps Manager.

Set the value of this field to a higher value, in seconds, if you are experiencing domain name resolution timeouts when pushing errands in PAS.

To modify the value of the **CF CLI Connection Timeout**, perform the following steps:

1. Select **Advanced Features**.

CF CLI Connection Timeout

15

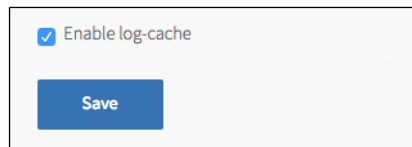

2. Add a value, in seconds, to the **CF CLI Connection Timeout** field.
3. Click **Save**.

Log Cache

Log Cache is an in-memory caching layer for logs and metrics. This Loggregator feature lets users filter and query logs through a CLI or API endpoints. Cached logs are available on demand. For more information about Log Cache, see [Enable Log Cache](#) in the *Configuring Logging in PASTopic*.

To configure the **Enable log-cache** checkbox, do the following:

1. Select **Advanced Features**.

A screenshot of a configuration panel. It contains a checkbox labeled 'Enable log-cache' which is checked. Below the checkbox is a blue button labeled 'Save'.

2. Select or deselect the **Enable log-cache** checkbox.
3. Click **Save**.

Database Connection Limits

You can configure the maximum number of concurrent database connections that diego and container networking components can have. Use the field beginning with **Maximum number of open connections...** for a given component. The placeholder values for each field are the default values.

When there are not enough connections available, such as during a time of heavy load, components may experience degraded performance and sometimes failure. To resolve or prevent this, you can increase and fine-tune database connection limits for the component.

⚠ warning: Decreasing the value of this field for a component may affect the amount of time it takes for it to respond to requests.

Step 22: Configure Errands

Errands are scripts that Ops Manager runs automatically when it installs or uninstalls a product, such as a new version of Pivotal Application Service (PAS). There are two types of errands: *post-deploy errands* run after the product is installed, and *pre-delete errands* run before the product is uninstalled.

By default, Ops Manager always runs all errands.

The PAS tile **Errands** pane lets you change these run rules. For each errand, you can select **On** to run it always or **Off** to never run it.

For more information about how Ops Manager manages errands, see the [Managing Errands in Ops Manager](#) topic.

💡 Note: Several errands, such as App Autoscaler and Notifications, deploy apps that provide services for your deployment. When one of these apps is running, selecting **Off** for the corresponding errand on a subsequent installation does not stop the app.

- **Smoke Test Errand** verifies that your deployment can do the following:
 - Push, scale, and delete apps
 - Create and delete orgs and spaces
- **Usage Service Errand** deploys the Pivotal Usage Service application, which Apps Manager depends on.
- **Apps Manager Errand** deploys Apps Manager, a dashboard for managing apps, services, orgs, users, and spaces. Until you deploy Apps Manager, you must perform these functions through the cf CLI. After Apps Manager has been deployed, Pivotal recommends setting this errand to **Off** for subsequent PAS deployments. For more information about Apps Manager, see the [Getting Started with the Apps Manager](#) topic.
- **Notifications Errand** deploys an API for sending email notifications to your PCF platform users.

💡 Note: The Notifications app requires that you [configure SMTP](#) with a username and password, even if you set the value of **SMTP Authentication Mechanism** to `none`.

- **Notifications UI Errand** deploys a dashboard for users to manage notification subscriptions.
- **App Autoscaler Errand** enables you to configure your apps to automatically scale in response to changes in their usage load. See the [Scaling an Application Using Autoscaler](#) topic for more information.
- **NFS Broker Errand** enables you to use NFS Volume Services by installing the NFS Broker app in PAS. See the [Enabling NFS Volume Services](#) topic for more information.

Step 23: Configure Router (or HAProxy) to Elastic Load Balancer

1. In the PAS tile, click **Resource Config**.

Resource Config

| JOB | INSTANCES | PERSISTENT DISK TYPE | VM TYPE | LOAD BALANCERS | INTERNET CONNECTED |
|-------------------------------|--------------|----------------------|---|----------------|-------------------------------------|
| Consul | 1 | Automatic: 1 GB | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| NATS | 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| File Storage | Automatic: 1 | Automatic: 100 GB | Automatic: medium.mem (cpu: 1, ram: 6 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |

| CredHub | Automatic: 0 | None | Automatic: large (cpu: 2, ram: 8 GB, disk: 16 GB) | | <input checked="" type="checkbox"/> |

Save

2. Enter the name of your SSH load balancer depending on which release you are using.

- **Pivotal Application Service (PAS):** In the **Load Balancers** field of the **Diego Brain** row, enter the value of `ssh_elb_name` from the Terraform output.
- **Small Footprint Runtime:** In the **Load Balancers** field of the **Control** row, enter the value of `ssh_elb_name` from the Terraform output.

3. In the **Load Balancers** field of the **Router** row, enter the value of `web_elb_name` from the Terraform output.

Note: If you are using HAProxy in your deployment, then put the name of the load balancers in the **Load Balancers** field of the **HAProxy** row instead of the **Router** row. For a high availability configuration, scale up the HAProxy job to more than one instance.

4. In the **Load Balancers** field of the **TCP Router** row, enter the value of `tcp_elb_name` from the Terraform output.

5. Click **Save**.

Step 24: (Optional) Scale Down and Disable Resources

Note: The **Resource Config** pane has fewer VMs if you are installing the **Small Footprint Runtime**.

Note: The Small Footprint Runtime does not default to a highly available configuration. It defaults to the minimum configuration. If you want to make the Small Footprint Runtime highly available, scale the **Compute**, **Router**, and **Database** VMs to `3` instances and scale the **Control** VM to `2` instances.

Pivotal Application Service (PAS) defaults to a highly available resource configuration. However, you may need to perform additional procedures to make your deployment highly available. See the [Zero Downtime Deployment and Scaling in CF](#) and the [Scaling Instances in PAS](#) topics for more information.

If you do not want a highly available resource configuration, you must scale down your instances manually by navigating to the **Resource Config** section and using the dropdowns under **Instances** for each job.

By default, PAS also uses an internal filestore and internal databases. If you configure PAS to use external resources, you can disable the corresponding

system-provided resources in Ops Manager to reduce costs and administrative overhead.

To disable specific VMs in Ops Manager, do the following:

1. Click **Resource Config**.
2. If you configured PAS to use an external S3-compatible filestore, enter in **Instances** in the **File Storage** field.
3. If you selected **External** when configuring the UAA, System, and CredHub databases, edit the following fields:
 - **MySQL Proxy**: Enter in **Instances**.
 - **MySQL Server**: Enter in **Instances**.
 - **MySQL Monitor**: Enter in **Instances**.
4. If you disabled TCP routing, enter **Instances** in the **TCP Router** field.
5. If you are not using HAProxy, enter **Instances** in the **HAProxy** field.
6. Click **Save**.

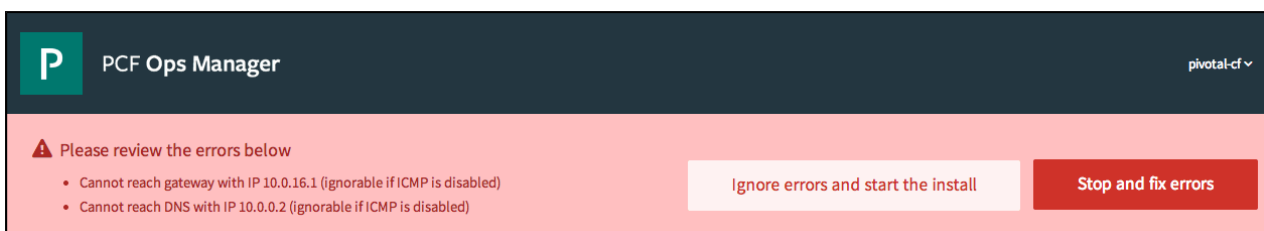

Step 25: Download Stemcell

This step is only required if your Ops Manager does not already have the stemcell version required by PAS. For more information about importing stemcells, see [Importing and Managing Stemcells](#).

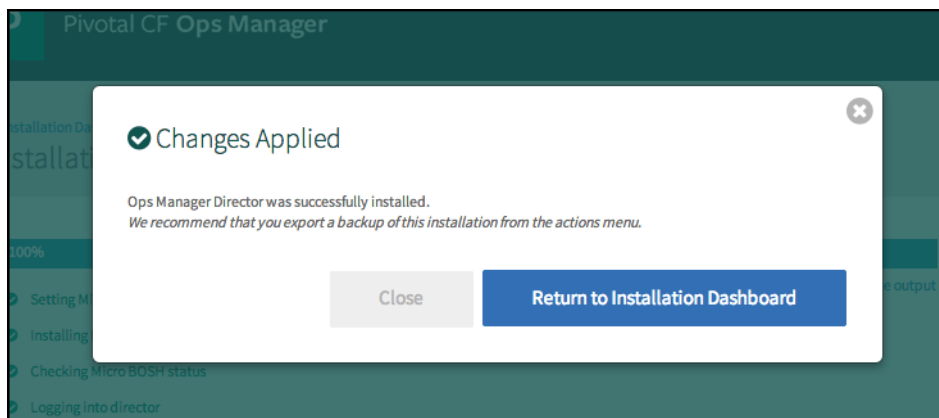

1. Open the [Stemcell product page](#) in the Pivotal Network. *Note, you may have to log in.*
2. Download the appropriate stemcell version targeted for your IaaS.
3. Navigate to **Stemcell Library** in the **Installation Dashboard**.
4. Click **Import Stemcell** to import the downloaded stemcell file.
5. When prompted, enable the Ops Manager product checkbox to stage your stemcell.
6. Click **Apply Stemcell to Products**.

Step 26: Complete the PAS Installation

1. Click the **Installation Dashboard** link to return to the Installation Dashboard.
2. Click **Apply Changes**. If the following ICMP error message appears, click **Ignore errors and start the install**.

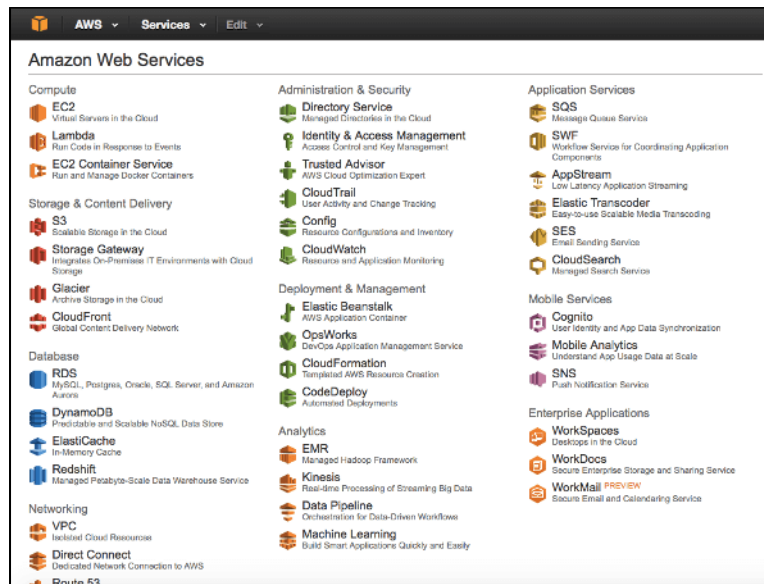

The install process generally requires a minimum of 90 minutes to complete. The image shows the Changes Applied window that displays when the installation process successfully completes.

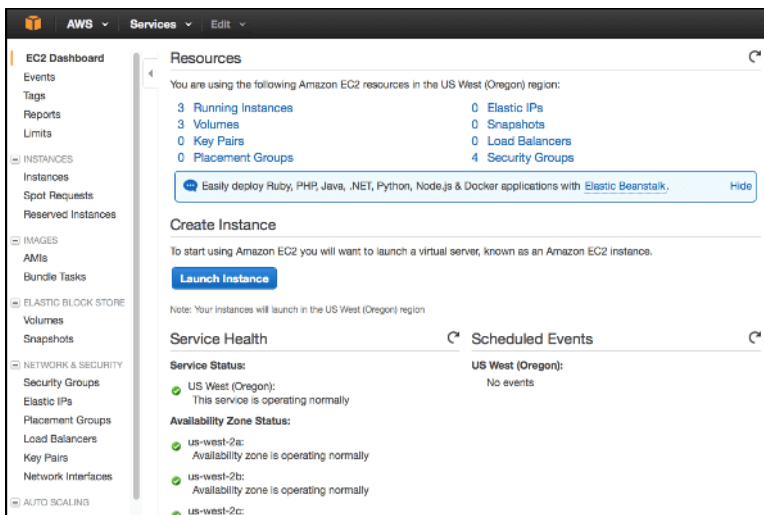

Deleting PCF from AWS

Page last updated:

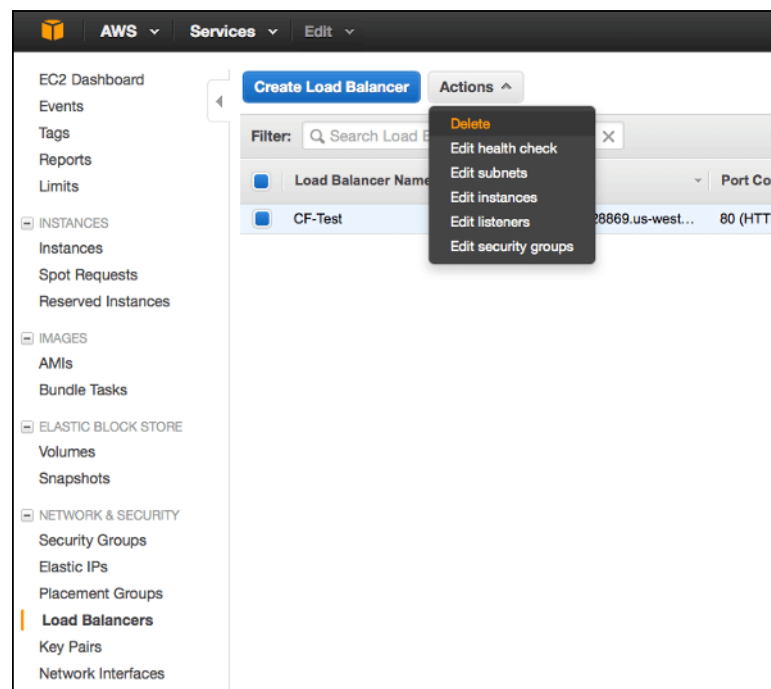

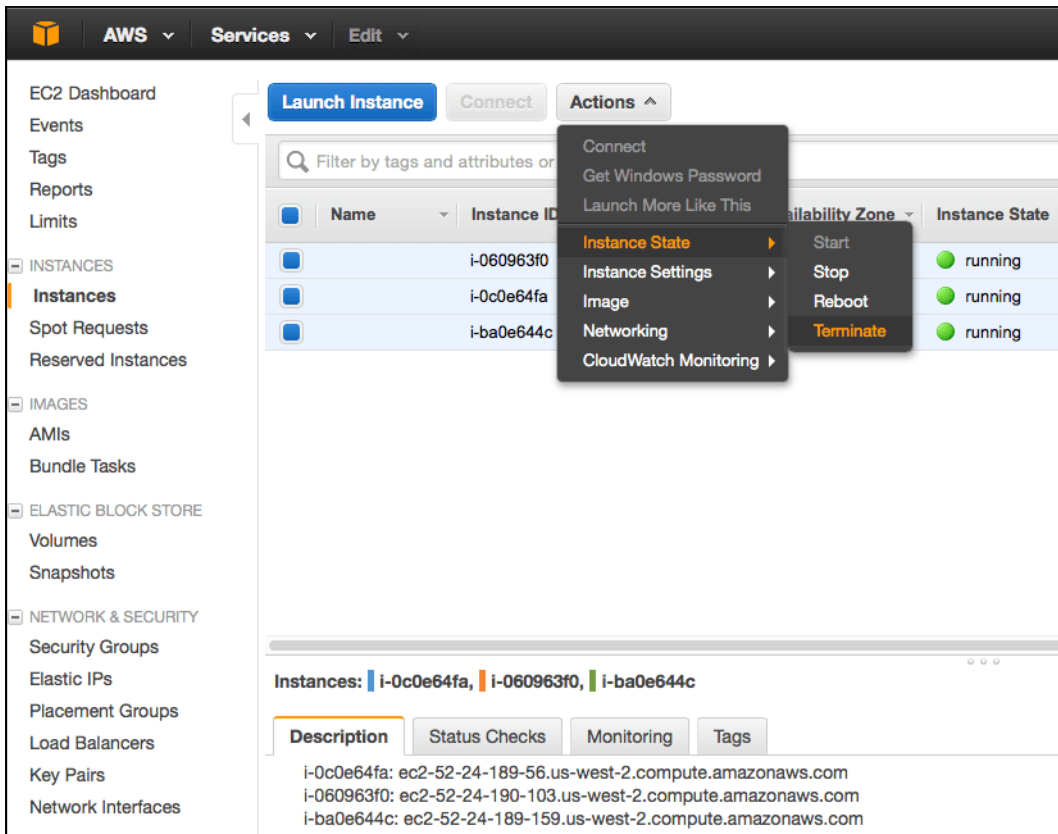

When you deploy [Pivotal Cloud Foundry](#) (PCF) to Amazon Web Services (AWS), you provision a set of resources. This topic describes how to delete the AWS resources associated with a PCF deployment. You can use the AWS console to remove an installation of all components, but retain the objects in your bucket for a future deployment.

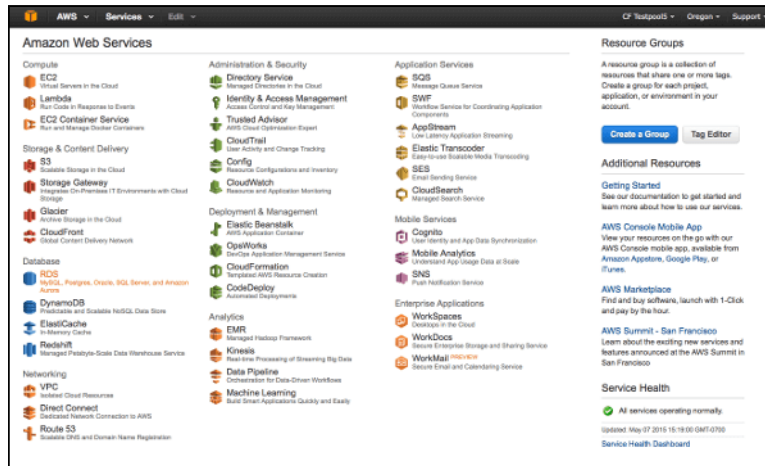

1. Log into your AWS Console.
2. Navigate to your EC2 dashboard. Select **Instances** from the menu on the left side.

3. Terminate all your instances.

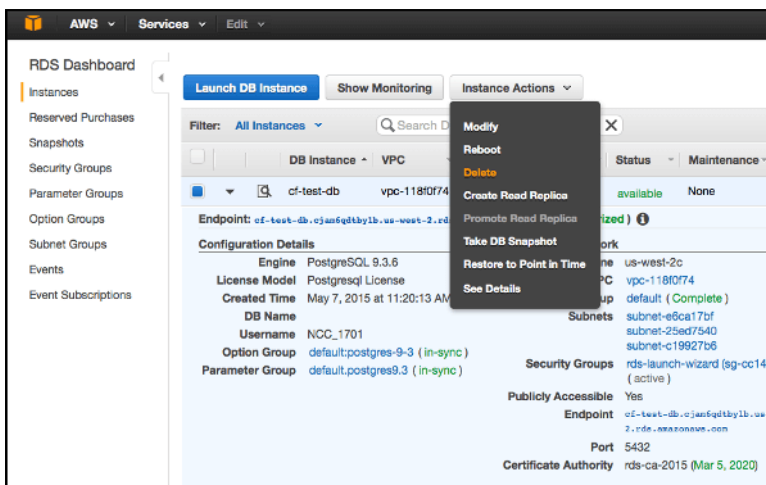

4. Select **Load Balancers**. Delete all load balancers.

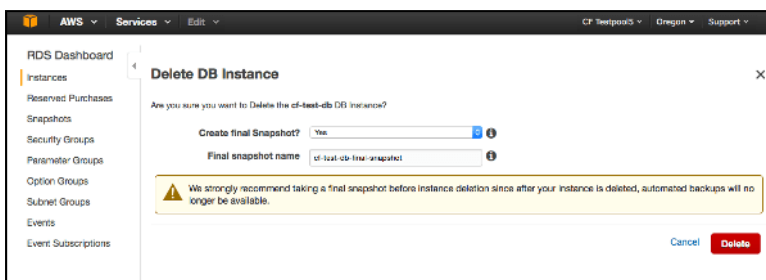

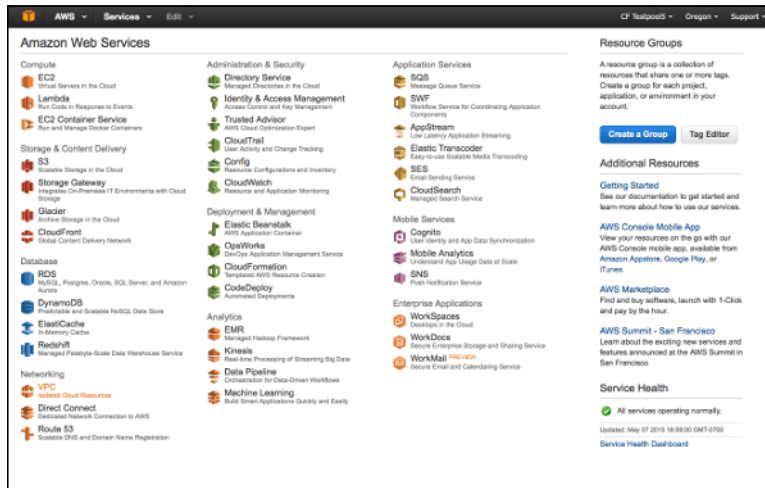

5. From the AWS Console, select RDS.

6. Select **Instances** from the menu on the left side. Delete the RDS instances.

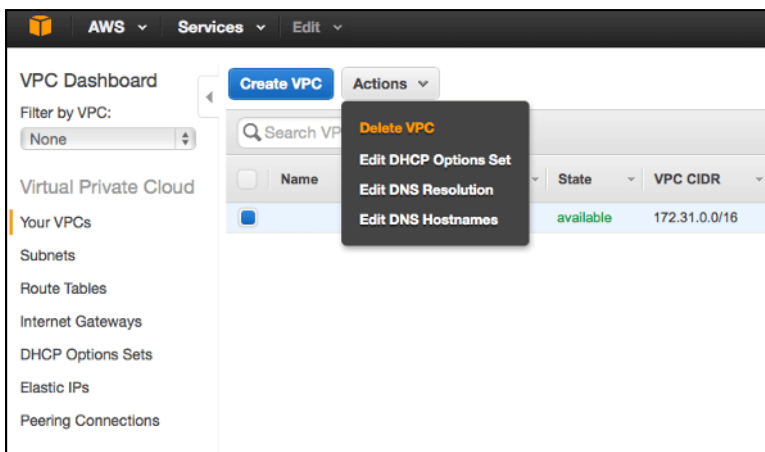

7. Select **Create final Snapshot** from the dropdown. Click **Delete**.

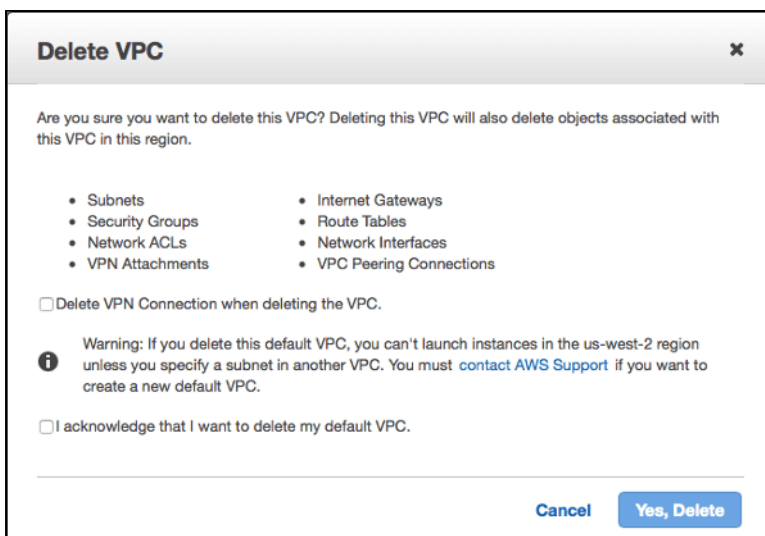

8. From the AWS Console, select VPC.

9. Select **Your VPCs** from the menu on the left. Delete the VPCs.

10. Check the box to acknowledge that you want to delete your default VPC. Click **Yes, Delete**.

Creating a Proxy ELB for Diego SSH

If you want to allow SSH connections to application containers, you may want to use an Elastic Load Balancer (ELB) as the SSH proxy.

Perform the steps below to create this ELB:

1. On the EC2 Dashboard, click **Load Balancers**.
2. Click **Create Load Balancer**, and configure a classic load balancer with the following information:

Step 1: Define Load Balancer

Basic Configuration

This wizard will walk you through setting up a new load balancer. Begin by giving your new load balancer a unique name so that you can identify it from other load balancers you might create. You will also need to configure ports and protocols for your load balancer. Traffic from your clients can be routed from any load balancer port to any port on your EC2 instances. By default, we've configured your load balancer with a standard web server on port 80.

Load Balancer name: my-SSH-ELB

Create LB Inside: vpc-4b38852e (10.0.0.0/16) | pcf-vpc

Create an internal load balancer: ☐ (what's this?)

Enable advanced VPC configuration: ☒

Listener Configuration:

| Load Balancer Protocol | Load Balancer Port | Instance Protocol | Instance Port |
|------------------------|--------------------|-------------------|---------------|
| TCP | 2222 | TCP | 2222 |

Select Subnets

You will need to select a Subnet for each Availability Zone where you wish traffic to be routed by your load balancer. If you have instances in only one Availability Zone, please select at least two Subnets in different Availability Zones to provide higher availability for your load balancer.

VPC vpc-4b38852e (10.0.0.0/16) | pcf-vpc

Please select at least two Subnets in different Availability Zones to provide higher availability for your load balancer.

Available Subnets

| Actions | Availability Zone | Subnet ID | Subnet CIDR | Name |
|---------|-------------------|-----------------|--------------|--------------------|
| + | us-west-1b | subnet-b63be1ef | 10.0.16.0/20 | pcf-private-subnet |
| + | us-west-1b | subnet-b73be1ee | 10.0.2.0/24 | pcf-rds-subnet-1 |
| + | us-west-1c | subnet-c8f095ad | 10.0.3.0/24 | pcf-rds-subnet-2 |

Selected Subnets

| Actions | Availability Zone | Subnet ID | Subnet CIDR | Name |
|---------|-------------------|-----------------|-------------|-------------------|
| - | us-west-1b | subnet-b43be1ed | 10.0.0.0/24 | pcf-public-subnet |

- Enter a load balancer name.
 - **Create LB Inside:** Select the **pcf-vpc** VPC where your PCF installation lives.
 - Ensure that the **Create an internal load balancer** checkbox is not selected.
3. Under **Load Balancer Protocol**, ensure that this ELB is listening on TCP port **2222** and forwarding to TCP port **2222**.
 4. Under **Select Subnets**, select the public subnet.
 5. On the **Assign Security Groups** page, create a new Security Group. This Security Group should allow inbound traffic on TCP port **2222**.

Create Security Group

Security group name: PCF_SSH_ELB_SecurityGroup

Description:

VPC: vpc-4b38852e (10.0.0.0/16) | pcf-vpc

* denotes default VPC

Security group rules:

Inbound | Outbound

| Type | Protocol | Port Range | Source |
|-----------------|----------|------------|----------------------|
| Custom TCP Rule | TCP | 2222 | Anywhere (0.0.0.0/0) |

Add Rule

Cancel Create

- The **Configure Security Settings** page displays a security warning because your load balancer is not using a secure listener. You can ignore this warning.

1. Define Load Balancer 2. Assign Security Groups 3. Configure Security Settings 4. Configure Health Check 5. Add EC2 Instances 6. Add Tags 7. Review

Step 3: Configure Security Settings

Improve your load balancer's security. Your load balancer is not using any secure listener.

If your traffic to the load balancer needs to be secure, use either the HTTPS or the SSL protocol for your front-end connection. You can go back to the first step to add/configure secure listeners under [Basic Configuration](#) section. You can also continue with current settings.

- Click **Next: Configure Health Check**.

1. Define Load Balancer 2. Assign Security Groups 3. Configure Security Settings 4. Configure Health Check

Step 4: Configure Health Check

Your load balancer will automatically perform health checks on your EC2 instances. If an instance fails a health check, it is removed from the load balancer. Customize the health check to meet your needs.

Ping Protocol: TCP

Ping Port: 2222

Advanced Details

Response Timeout: 5 seconds

Health Check Interval: 30 seconds

Unhealthy Threshold: 2

Healthy Threshold: 10

- Select **TCP** in **Ping Protocol** on the **Configure Health Check** page. Ensure that the **Ping Port** value is **2222** and set the **Health Check Interval** to **30** seconds.

- Click **Next: Add EC2 Instances**.

- Accept the defaults on the **Add EC2 Instances** page and click **Next: Add Tags**.

- Accept the defaults on the **Add Tags** page and click **Review and Create**.

- Review and confirm the load balancer details, and click **Create**.

- With your DNS service (for example, Amazon Route 53), create an `ssh.system.YOUR-SYSTEM-DOMAIN` DNS record that points to this ELB that you just created.

Create Record Set

Name:

ssh.your-system-domain.com.

Type:

CNAME – Canonical name

Alias:

☐ Yes
 ☒ No

TTL (Seconds):

300

1m

5m

1h

1d

Value:

your-elb-domain

The domain name that you want to resolve to instead of the value in the Name field.

Example:

www.example.com

14. You can now use this ELB to the SSH Proxy of your Pivotal Application Service (PAS) installation.

15. In PAS, select **Resource Config**, and enter the ELB that you just created in the **Diego Brain** row, under the **Load Balancers** column.

| | | | | |
|-------------|---|-----------------|---|-------------|
| UAA | 1 | None | Automatic: t2.small (cpu: 1, ram: 2 GB, disk: 2 GB) | |
| Diego Brain | 1 | Automatic: 1 GB | Automatic: m3.medium (cpu: 1, ram: 3.75 GB, disk: 4 GB) | passion-elb |
| Diego Cell | 3 | None | m3.2xlarge (cpu: 8, ram: 30 GB, disk: 64 GB) | |

Upgrading BOSH Director on AWS

This topic describes how to upgrade BOSH Director for Pivotal Cloud Foundry (PCF) on Amazon Web Services (AWS).

Complete the tasks in this topic as part of the Ops Manager upgrade process. For more information, see [Upgrading Pivotal Cloud Foundry](#).

Overview

In this procedure, you create an Ops Manager VM instance to host the upgraded version of Ops Manager. Then, to complete the Ops Manager upgrade, you export your existing Ops Manager installation onto this new VM.

For PCF installations on AWS, the VM that hosts the new version of Ops Manager uses an Amazon Machine Image (AMI) specific to your region.

To create an Ops Manager VM instance, do the following:

1. Retrieve the Ops Manager AMI ID. See [Retrieve Ops Manager AMI ID](#).
2. Launch the AMI. See [Launch Ops Manager AMI](#).
3. Edit the Ops Manager DNS A Record. See [Edit Ops Manager DNS A Record](#).

Prerequisites

To complete the Ops Manager upgrade, you must have your Ops Manager decryption passphrase. You defined this decryption passphrase during the initial installation of Ops Manager.

Retrieve Ops Manager AMI ID

Ops Manager has a different AMI ID for each region. Retrieve and record the AMI ID for your region. You use this AMI ID when launching the Ops Manager AMI instance.

To retrieve the AMI ID for Ops Manager, perform the following steps:

1. Navigate to the **Pivotal Cloud Foundry Operations Manager** section of [Pivotal Network](#).
2. Select the version of PCF you want to install from the **Releases** dropdown.
3. In the **Release Download Files**, click the file named **Pivotal Cloud Foundry Ops Manager for AWS** to download a PDF.
4. Open the PDF and record the AMI ID for your region.

Launch Ops Manager AMI

Use the AMI ID for your region to launch an AMI instance that hosts the new version of Ops Manager.

To launch the AMI for Ops Manager, perform the following steps:

1. Navigate to your EC2 Dashboard.
2. Click **AMIs** from the **Images** menu.
3. Select **Public images** from the drop-down filter that says **Owned by me**.
4. Paste the AMI ID for your region into the search bar and press enter.

Note: There is a different AMI for each region. If you cannot locate the AMI for your region, verify that you have set your AWS Management Console to your desired region. If you still cannot locate the AMI, log in to the [Pivotal Network](#) and file a support ticket.

Launch Actions

Public images

AMI Name : pivotal-ops AMI ID :

| Name | AMI Name | AMI ID | Source |
|------|---|--------|------------------|
| | pivotal-ops-manager-20150323T224150-dcce5db | ami- | 152787392610/... |

5. (Optional) If you want to encrypt the VM that runs Ops Manager with AWS Key Management Service (KMS), perform the following additional steps:
 - a. Right click the row that lists your AMI and click **Copy AMI**.
 - b. Select your **Destination region**.
 - c. Enable **Encryption**. For more information about AMI encryption, see [Encryption and AMI Copy](#) from the *Copying an AMI* topic in the AWS documentation.
 - d. Select your **Master Key**. To create a new custom key, see [Creating Keys](#) in the AWS documentation.
 - e. Click **Copy AMI**. You can use the new AMI you copied for the following steps.
6. Select the row that lists your Ops Manager AMI and click **Launch**.
7. Choose **m3.large** for your instance type and click **Next: Configure Instance Details**.

| | Family | Type | vCPUs | Memory (GiB) | Instance Storage (GB) |
|-------------------------------------|-----------------|--------------------------------|-------|--------------|-----------------------|
| <input type="checkbox"/> | Micro instances | t1.micro Free tier eligible | 1 | 0.613 | EBS only |
| <input checked="" type="radio"/> | General purpose | t2.micro Free tier eligible | 1 | 1 | EBS only |
| <input checked="" type="radio"/> | General purpose | t2.small | 1 | 2 | EBS only |
| <input checked="" type="radio"/> | General purpose | t2.medium | 2 | 4 | EBS only |
| <input type="checkbox"/> | General purpose | m3.medium | 1 | 3.75 | 1 x 4 (SSD) |
| <input checked="" type="checkbox"/> | General purpose | m3.large | 2 | 7.5 | 1 x 32 (SSD) |

8. Configure the following for your instance:
 - **Network:** Select the VPC that you created.
 - **Subnet:** Select `pcf-public-subnet-az0`.
 - **Auto-assign for Public IP:** Select **Enable**.
 - **IAM role:** Select the IAM role associated with your pc-f-user profile. If you have not created one, click **Create new IAM role** and follow the [Guidelines for Creating User Roles on AWS](#).
 - For all other fields, accept the default values.

1. Choose AMI 2. Choose Instance Type 3. Configure Instance 4. Add Storage 5. Tag Instance 6. Configure Security Group 7. Review

Step 3: Configure Instance Details

Configure the instance to suit your requirements. You can launch multiple instances from the same AMI, request Spot Instances to take advantage of the lower pricing, assign an access management role to the instance, and more.

Number of instances 1

Purchasing option ☐ Request Spot Instances

Network vpc-8ec593eb (10.0.0.0/16) | pc-f-vpc [Create new VPC](#)

Subnet subnet-fe8129d5 (10.0.0.0/24) | public-az1 | 250 IP Addresses available [Create new subnet](#)

Auto-assign Public IP Enable

IAM role None [Create new IAM role](#)

Shutdown behavior Stop

Enable termination protection ☐ Protect against accidental termination

Monitoring ☐ Enable CloudWatch detailed monitoring
[Additional charges apply.](#)

Tenancy Shared tenancy (multi-tenant hardware)
[Additional charges will apply for dedicated tenancy.](#)

9. Click **Next: Add Storage** and adjust the **Size (GiB)** value. The default persistent disk value is 50 GB. Pivotal recommends increasing this value to a minimum of 100 GB.

1. Choose AMI 2. Choose Instance Type 3. Configure Instance 4. Add Storage 5. Tag Instance 6. Configure Security Group 7. Review

Step 4: Add Storage

Your instance will be launched with the following storage device settings. You can attach additional EBS volumes and instance store volumes to your instance, or edit the settings of the root volume. You can also attach additional EBS volumes after launching an instance, but not instance store volumes. [Learn more](#) about storage options in Amazon EC2.

| Type | Device | Snapshot | Size (GiB) | Volume Type | IOPS | Delete on Termination | Encrypted |
|------------------|-----------|---------------|------------|-----------------------|------------|-------------------------------------|---------------|
| Root | /dev/sda1 | snap-f1ce6d7e | 100 | General Purpose (SSD) | 150 / 3000 | <input checked="" type="checkbox"/> | Not Encrypted |
| Instance Store 0 | /dev/sdb | N/A | N/A | N/A | N/A | N/A | Not Encrypted |

[Add New Volume](#)

- Click **Next: Tag Instance**.
- On the **Add Tags** page, add a tag with the key `Name` and value `pcf-ops-manager`.
- Click **Next: Configure Security Group**.
- Select the `pcf-ops-manager-security-group` that you created in [Step 5: Configure a Security Group for Ops Manager](#).
- Click **Review and Launch** and confirm the instance launch details.
- Click **Launch**.
- Select the `pcf-ops-manager-key` key pair, confirm that you have access to the private key file, and click **Launch Instances**. You use this key pair to access the Ops Manager VM.

Select an existing key pair or create a new key pair

A key pair consists of a **public key** that AWS stores, and a **private key file** that you store. Together, they allow you to connect to your instance securely. For Windows AMIs, the private key file is required to obtain the password used to log into your instance. For Linux AMIs, the private key file allows you to securely SSH into your instance.

Note: The selected key pair will be added to the set of keys authorized for this instance. [Learn more about removing existing key pairs from a public AMI.](#)

Choose an existing key pair

Select a key pair

pcf

☒ I acknowledge that I have access to the selected private key file (pcf.pem), and that without this file, I won't be able to log into my instance.

Cancel Launch Instances

Edit Ops Manager DNS A Record

After you deploy the new Ops Manager VM, edit the Ops Manager DNS record in the EC2 dashboard to point to the IP address for the new VM.

To edit the Ops Manager DNS A record, do the following:

- Click **View Instances** to access the **Instances** page on the EC2 Dashboard.
- Select the VM that you created in the previous section.
- Locate the **IPv4 Public IP** value in the instance **Description** tab, and record this value for use in the next step.
- In your DNS provider, edit the **A** record for `pcf.YOUR-SYSTEM-DOMAIN` to point to the IP address recorded in the previous step.

Next Steps

After you complete this procedure, continue the upgrade instructions in [Upgrading Pivotal Cloud Foundry](#) topic.

Installing Pivotal Cloud Foundry on Azure

This topic describes how to install Pivotal Cloud Foundry (PCF) on Microsoft Azure.

It includes resource requirements, prerequisites, instructions for installing PCF on Azure, and additional resources.

Overview

You can install PCF on Azure, Azure Government Cloud, or Azure Germany. For more information about Azure regions, see [Azure regions](#) in the Microsoft Azure documentation.

You can install PCF on Azure with the Pivotal Application Service (PAS) runtime. There are resource requirements specific to both PAS and Azure. Ensure you meet the requirements for PAS and the requirements specific to Azure before installing PCF on Azure. For more information, see [Requirements](#).

Requirements

This section lists the following resource requirements for installing PCF on Azure:

- PAS resource requirements. See [PAS Resource Requirements](#).
- Azure-specific resource requirements. See [Azure Resource Requirements](#).

PAS Resource Requirements

The following are general resource requirements for deploying and managing a PCF deployment with Ops Manager and PAS:

- PAS requires sufficient IP allocation. The following lists the minimum required IP allocations:
 - One static IP address for either HAProxy or one of your Gorouters
 - One static IP address for each job in the Ops Manager tile. See the Ops Manager **Resource Config** pane for each tile for a full list.
 - One static IP address for each job listed below:
 - Consul
 - NATS
 - File Storage
 - MySQL Proxy
 - MySQL Server
 - Backup Restore Node
 - HAProxy
 - Router
 - MySQL Monitor
 - Diego Brain
 - TCP Router
 - One IP for each VM instance created by the service.
 - An additional IP address for each compilation worker. Use the following formula to determine the total IPs required:

$$\text{IPs needed} = \text{static IPs} + \text{VM instances} + \text{compilation workers}$$
 - Pivotal recommends that you allocate at least 36 dynamic IP addresses when deploying Ops Manager and PAS. BOSH requires additional dynamic IP addresses during installation to compile and deploy VMs, install PAS, and connect to services.
- Pivotal recommends using a network without DHCP for deploying PAS VMs.

Note: If you have DHCP, refer to the [Troubleshooting Guide](#) to avoid issues with your installation.

Azure Resource Requirements

The following are the minimum resource requirements for deploying a PCF deployment with Ops Manager and PAS on Azure:

- An OS disk of 120 GB for the Ops Manager VM.

 **Note:** Ops Manager v1.11 requires a Director VM with at least 8 GB memory.

- A minimum of the following VM instance limits in your Azure account. The number of VMs required depends on the number of tiles and availability zones you plan to deploy. The following VM guidelines apply to the PAS and Small Footprint PAS runtimes:
 - **PAS:** A new Azure deployment requires the following VMs for PAS and Ops Manager:

| VM Type | VM Count |
|---------|----------|
| F1s | 27 |
| F2s | 4 |
| F4s | 4 |
| DS11 v2 | 1 |
| DS12 v2 | 1 |

 **Note:** If you are deploying a test or sandbox PCF that does not require high availability, then you can scale down the number of VM instances in your deployment. For more information, see [Scaling PAS](#).

- **Small Footprint PAS:** A new Azure deployment requires the following VMs for Small Footprint PAS and Ops Manager:

| | VM Type | VM Count | Notes |
|----------------------------|---------|----------|---------------------------------|
| Small Footprint PAS | DS11 v2 | 1 | |
| | DS12 v2 | 2 | |
| | F2s | 0 | Add 1 to count if using HAProxy |
| | F1s | 5 | |
| Ops Manager | DS2 v2 | 1 | |
| | F4s | 4 | |

 **Note:** Some VM instance types are only supported in certain Azure regions. For more information, see [Products available by region](#) in the Azure documentation. To deploy PCF on an Azure region that does not support the above VM instance types, you must override the default VM sizes. For more information, see [Overriding defaults with custom disk types](#) in the Ops Manager API documentation. Changing the default VM sizes may increase the cost of your deployment.

Prerequisites

Before installing PCF on Azure, you must do the following:

- Install the Azure CLI v2.0. For instructions on how to install the Azure CLI for your operating system, see [Preparing to Deploy Ops Manager on Azure Manually](#).
- Configure sufficient IP allocation for PAS. For more information about IP allocation requirements, see [PAS Resource Requirements](#).
- Create an SSL certificate for your PCF domain.

 **Note:** To deploy PCF to a production environment, you must obtain a certificate from a certificate authority. Pivotal recommends using a self-signed certificate generated by Ops Manager for development and testing purposes only.

- Assign administrative rights to a domain for PCF. You must be able to add wildcard records to this domain.
- Create a wildcard DNS record that points to your router or load balancer. Alternatively, you can use a service such as xip.io. For example, `203.0.113.0.xip.io`. Then, create at least one wildcard TLS certificate that matches the DNS record you configured.

 **Note:** With a wildcard DNS record, every hostname in your domain resolves to the IP address of your router or load balancer. For example, if you create a DNS record `*.example.com` pointing to your router, every app deployed to the `example.com` domain resolves to the IP address of your router.

- Create one or more NTP servers, if the NTP servers are not already provided by your Azure project.
- Install the most recent version of the Cloud Foundry Command Line Interface (cf CLI). See [Cloud Foundry Command Line Interface](#) in GitHub.
- **(Optional)** Configure external storage. Pivotal recommends using external storage if possible. For more information about how file storage location affects platform performance and stability during upgrades, see [Configure File Storage](#).

- **(Optional)** Configure external databases. Pivotal recommends using external databases in production deployments for BOSH Director and PAS. An external database must be configured to use the UTC timezone.
- **(Optional)** Configure external user stores. When you deploy PCF, you can select a SAML user store for Ops Manager or a SAML or LDAP user store for PAS, to integrate existing user accounts.

Install PCF on Azure

You can install PCF on Azure either manually or using Terraform.

To install PCF on Azure, do one of the following:

- Install PCF on Azure manually. See [Installing PCF on Azure Manually](#).
- Install PCF on Azure using Terraform. See [Installing PCF on Azure Using Terraform](#).

Install PCF on Azure Government Cloud

To install PCF on Azure Government Cloud, see [Configuring BOSH Director on Azure Government Cloud](#).

Install PCF on Azure Germany

To install PCF in Azure Germany, see [Configuring BOSH Director on Azure Germany](#).

Additional Resources

The following are additional resources related to installing PCF on GCP:

- For information about troubleshooting the PCF on Azure install process, see [Troubleshooting PCF on Azure](#).
- For production-level deployment options for PCF on Azure, see [Reference Architecture for Pivotal Cloud Foundry on Azure](#).
- For information about how to manage IaaS users and credentials in Azure, see [Azure security documentation](#).
- For recommendations on how to create and scope Azure accounts for PCF, see [IaaS Permissions Guidelines](#).
- For information about deleting a PCF on Azure installation, see [Deleting a PCF on Azure Installation](#).
- For information about upgrading PCF on Azure, see [Upgrading BOSH Director on Azure](#).

Installing PCF on Azure Manually

This topic explains how to install Pivotal Cloud Foundry (PCF) on Microsoft Azure manually.

To install PCF on Azure manually, do the following:

1. Deploy Ops Manager. See [Deploying Ops Manager on Azure Manually](#).
2. Configure BOSH Director. See [Configuring BOSH Director on Azure Manually](#).
3. Deploy PAS. See [Deploying PAS on Azure](#).

Preparing to Deploy Ops Manager on Azure Manually

Page last updated:

This topic describes how to prepare Azure to deploy Ops Manager. You must deploy Ops Manager to deploy Pivotal Application Service (PAS) or Pivotal Container Service (PKS).

After you complete this procedure, follow the instructions in one of the following topics:

- [Deploying Ops Manager to Azure Using Terraform](#)
- [Launching a BOSH Director Instance with an ARM Template](#) 
- [Deploying Ops Manager on Azure Manually](#)

Step 1: Install and Configure the Azure CLI

1. Install the Azure CLI 2.0 by following the instructions for your operating system in the [Azure documentation](#) .
2. Set your cloud with the `--name` value corresponding to the Azure environment on which you are installing Ops Manager:
 - **Azure:** `AzureCloud` .
 - **Azure China:** `AzureChinaCloud` . If logging in to `AzureChinaCloud` fails with a `CERT_UNTRUSTED` [error](#) , use the latest version of node, 4.x or later.
 - **Azure Government Cloud:** `AzureUSGovernment` . Azure Government Cloud is only supported in Ops Manager v1.10 and later.
 - **Azure Germany:** `AzureGermanCloud` .

```
$ az cloud set --name AzureCloud
```

Note: For more information about installing Ops Manager in the China Region, see [Install in the China Region](#) in *Installing PCF in Airgapped Environments* in the Pivotal documentation.

3. Log in:

```
$ az login
```

Authenticate by navigating to the URL in the output, entering the provided code, and clicking your account.

Step 2: Set Your Default Subscription

1. To list your Azure subscriptions, run the following command:

```
$ az account list
[
  {
    "id": "12345678-1234-5678-1234-567891234567",
    "name": "Sample Subscription",
    "user": {
      "name": "Sample Account",
      "type": "user"
    },
    "tenantId": "11111111-1234-5678-1234-678912345678",
    "state": "Enabled",
    "isDefault": true,
    "registeredProviders": [],
    "environmentName": "AzureCloud"
  },
  {
    "id": "87654321-1234-5678-1234-678912345678",
    "name": "Sample Subscription1",
    "user": {
      "name": "Sample Account1",
      "type": "user"
    },
    "tenantId": "22222222-1234-5678-1234-678912345678",
    "state": "Enabled",
    "isDefault": false,
    "registeredProviders": [],
    "environmentName": "AzureCloud"
  }
]
```

- a. Identify your default subscription in the output of this command by locating the subscription listed that has `isDefault` set to `true`. To deploy Ops Manager to a different subscription, you must set the other subscription as the default. To set a new default subscription, run the following command:

```
$ az account set --subscription SUBSCRIPTION_ID
```

2. Record the value of the `id` set as the default. You use this value in future configuration steps.
3. Record the value of `tenantID` for your default subscription. This is your `TENANT_ID` for creating a service principal. If your `tenantID` value is not defined, you may be using a personal account to log in to your Azure subscription.

Step 3: Create an Azure Active Directory (AAD) Application

1. Run the following command to create an AAD application, replacing `PASSWORD` with a password of your choice. This is your `CLIENT_SECRET` for creating a service principal.

```
$ az ad app create --display-name "Service Principal for BOSH" \
--password "PASSWORD" --homepage "http://BOSHAzureCPI" \
--identifier-uris "http://BOSHAzureCPI"
```

Note: You can provide any string for the `homepage` and `identifier-uris` flags, but the value of `identifier-uris` must be unique within the organization associated with your Azure subscription. For the `homepage`, Pivotal recommends using `http://BOSHAzureCPI` as shown in the example above.

2. Record the value of `appId` from the output. This is your `APPLICATION_ID` for creating a service principal.

```
{
  "appId": "5c552e8f-b977-45f5-a50b-981cf17cb9d",
  "appPermissions": null,
  "availableToOtherTenants": false,
  "displayName": "Service Principal for BOSH",
  "homepage": "http://BOSHAzureCIP",
  "identifierUris": [
    "http://BOSHAzureCPI"
  ],
  "objectId": "f3884df4-7d1d-4894-a78c-c1fe75750436",
  "objectType": "Application",
  "replyUrls": []
}
```

Step 4: Create and Configure a Service Principal

1. To create a service principal, run `az ad sp create --id YOUR-APPLICATION-ID`, replacing `YOUR-APPLICATION-ID` with the `APPLICATION_ID` you recorded in the [previous step](#):

```
$ az ad sp create --id YOUR-APPLICATION-ID
{
  "appId": "5c552e8f-b977-45f5-a50b-981cfe17cb9d",
  "displayName": "Service Principal for BOSH",
  "objectId": "cc13c685-4c3b-461e-ae96-7a0563960b83",
  "objectType": "ServicePrincipal",
  "servicePrincipalNames": [
    "5c552e8f-b977-45f5-a50b-981cfe17cb9d",
    "http://BOSHAzureCPI"
  ]
}
```

2. You must have the Contributor role on your service principal to deploy Ops Manager to Azure. To assign the Contributor role on your service principal, run the following command:

```
$ az role assignment create --assignee "SERVICE-PRINCIPAL-NAME" \
--role "Contributor" --scope /subscriptions/SUBSCRIPTION-ID
```

- For `SERVICE-PRINCIPAL-NAME`, use any value of `Service Principal Names` from the output above, such as `YOUR-APPLICATION-ID`.
- For `SUBSCRIPTION-ID`, use the ID of the default subscription that you recorded in [Step 2](#).

Note: If you need to use multiple resource groups for your deployment on Azure, you can define custom roles for your Service Principal. These roles allow BOSH to deploy to pre-existing network resources outside of the resource group. For more information, see [Multiple Resource Group Deployment](#) in *Reference Architecture for Pivotal Cloud Foundry on Azure* in the Pivotal documentation.

For more information about Azure Role-Based Access Control, refer to the [RBAC: Built-in roles](#) topic in the Azure documentation.

3. Verify the assignment by running the following command:

```
$ az role assignment list --assignee "SERVICE-PRINCIPAL-NAME"
[
  {
    "id": "/subscriptions/995b7eed-77ef-45ff-a5c9-1a405ffb8243/providers/Microsoft.Authorization/roleAssignments/32e644cf-ba1a-4f43-bf7c-68b4583e463",
    "name": "32e644cf-ba1a-4f43-bf7c-68b4583e463",
    "properties": {
      "principalId": "cc13c685-4c3b-461e-ae96-7a0563960b83",
      "principalName": "http://BOSHAzureCPI",
      "roleDefinitionId": "/subscriptions/995b7eed-77ef-45ff-a5c9-1a405ffb8243/providers/Microsoft.Authorization/roleDefinitions/b24988ac-6180-42a0-ab88-20f7382dd24c",
      "roleDefinitionName": "Contributor",
      "scope": "/subscriptions/995b7eed-77ef-45ff-a5c9-1a405ffb8243"
    },
    "type": "Microsoft.Authorization/roleAssignments"
  }
]
```

Step 5: Verify Your Service Principal

To verify your service principal, log in to your service principal with your `APPLICATION_ID`, `CLIENT_SECRET`, and `TENANT_ID`.

```
$ az login --username APPLICATION_ID --password CLIENT_SECRET \
--service-principal --tenant TENANT_ID
[
  {
    "cloudName": "AzureCloud",
    "id": "995b7eed-77ef-45ff-a5c9-1a405ffb8243",
    "isDefault": true,
    "name": "CF-Docs",
    "state": "Enabled",
    "tenantId": "29248f74-371f-4db2-9a50-c62a6877a0c1",
    "user": {
      "name": "5c552e8f-b977-45f5-a50b-981cfe17cb9d",
      "type": "servicePrincipal"
    }
  }
]
```

If you cannot log in, the service principal is invalid. Create a new service principal and try again.

Step 6: Perform Registrations

1. Register your subscription with Microsoft.Storage:

```
$ az provider register --namespace Microsoft.Storage
```

2. Register your subscription with Microsoft.Network:

```
$ az provider register --namespace Microsoft.Network
```

3. Register your subscription with Microsoft.Compute:

```
$ az provider register --namespace Microsoft.Compute
```

Next Steps

After you complete this topic, continue to one of the following topics:

- [Launching a BOSH Director Instance on Azure using Terraform](#): Perform the procedures in this topic to deploy BOSH Director using Terraform. Pivotal recommends using Terraform.
- [Launching a BOSH Director Instance with an ARM Template](#) [↗](#): Perform the procedures in this topic to deploy BOSH Director with an Azure Resource Manager (ARM) template.
- [Deploying Ops Manager on Azure Manually](#): Perform the procedures in this topic to deploy Ops Manager manually.

Deploying Ops Manager on Azure Manually

This topic describes how to deploy Ops Manager on Azure by using individual commands to create resources. Pivotal recommends this manual procedure for deploying to Azure China, Azure Germany, and Azure Government Cloud.

As an alternative to this procedure, you can use an Azure Resource Manager (ARM) template to create resources automatically. For information about using the ARM template, see the [Deploying BOSH and Ops Manager to Azure with ARM](#) topic.

Before you perform the procedures in this topic, you must have completed the procedures in [Preparing to Deploy Ops Manager on Azure Manually](#). After you complete the procedures in this topic, follow the instructions in [Configuring BOSH Director on Azure](#).

Note: If you are deploying BOSH and Ops Manager on Azure Stack, complete the procedures in [Install and configure CLI for use with Azure Stack](#) in the Microsoft documentation before following the procedures in this topic.

Note: The Azure portal sometimes displays the names of resources with incorrect capitalization. Always use the Azure CLI to retrieve the correctly capitalized name of a resource.

Step 1: Create Network Resources

To create network resources for your deployment, do the following:

1. Navigate to the Azure portal, click **Resource groups**, and click **Add** to create a new resource group for your deployment.
2. Enter a **Resource group name**, select your **Subscription**, and select a **Resource group location**. Click **Create**.
3. Export the name of your resource group as the environment variable `$RESOURCE_GROUP`.

```
$ export RESOURCE_GROUP="YOUR-RESOURCE-GROUP-NAME"
```

Note: If you are on a Windows machine, you can use `set` instead of `export`.

4. Export your location. For example, `westus`.

```
$ export LOCATION=westus
```

For a list of available locations, run `az account list-locations`.

5. Create a network security group named `pcf-nsg`.

```
$ az network nsg create --name pcf-nsg \
--resource-group $RESOURCE_GROUP \
--location $LOCATION
```

6. Add network security group rules to the `pcf-nsg` group to allow traffic to known ports from the public Internet.

```
$ az network nsg rule create --name ssh \
--nsg-name pcf-nsg --resource-group $RESOURCE_GROUP \
--protocol Tcp --priority 100 \
--destination-port-range '22'
```

```
$ az network nsg rule create --name http \
--nsg-name pcf-nsg --resource-group $RESOURCE_GROUP \
--protocol Tcp --priority 200 \
--destination-port-range '80'
```

```
$ az network nsg rule create --name https \
--nsg-name pcf-nsg --resource-group $RESOURCE_GROUP \
--protocol Tcp --priority 300 \
--destination-port-range '443'
```

```
$ az network nsg rule create --name diego-ssh \
--nsg-name pcf-nsg --resource-group $RESOURCE_GROUP \
--protocol Tcp --priority 400 \
--destination-port-range '2222'
```

- To block traffic from the public Internet, append `--source-address-prefixes AzureLoadBalancer` to allow traffic from only the Azure load balancer or `--source-address-prefixes VirtualNetwork` to only allow traffic from the virtual network.
- To allow traffic from both the Azure load balancer and the virtual network, create duplicates of each rule, one specifying `--source-address-prefixes AzureLoadBalancer` and one specifying `--source-address-prefixes VirtualNetwork`.

7. Create a network security group named `opsmgr-nsg`.

```
$ az network nsg create --name opsmgr-nsg \
--resource-group $RESOURCE_GROUP \
--location $LOCATION
```

8. Add a network security group rule to the `opsmgr-nsg` group to allow HTTP traffic to the Ops Manager VM.

```
$ az network nsg rule create --name http \
--nsg-name opsmgr-nsg --resource-group $RESOURCE_GROUP \
--protocol Tcp --priority 100 \
--destination-port-range 80
```

9. Add a network security group rule to the `opsmgr-nsg` group to allow HTTPS traffic to the Ops Manager VM.

```
$ az network nsg rule create --name https \
--nsg-name opsmgr-nsg --resource-group $RESOURCE_GROUP \
--protocol Tcp --priority 200 \
--destination-port-range 443
```

10. Add a network security group rule to the `opsmgr-nsg` group to allow SSH traffic to the Ops Manager VM.

```
$ az network nsg rule create --name ssh \
--nsg-name opsmgr-nsg --resource-group $RESOURCE_GROUP \
--protocol Tcp --priority 300 \
--destination-port-range 22
```

- To block traffic from the public Internet, append `--source-address-prefixes AzureLoadBalancer` to allow traffic from only the Azure load balancer or `--source-address-prefixes VirtualNetwork` to only allow traffic from the virtual network.
- To allow traffic from both the Azure load balancer and the virtual network, create duplicates of each rule, one specifying `--source-address-prefixes AzureLoadBalancer` and one specifying `--source-address-prefixes VirtualNetwork`.
- Optionally, if you want to use private IP ranges with Ops Manager and allow all internal traffic, you can create the Network Security Groups to allow all internal traffic.

```
$ az network nsg rule create --name internal-virtual-network \
--nsg-name internal-traffic --resource-group $RESOURCE_GROUP \
--protocol Tcp --priority 100 \
--destination-port-ranges '*' \
--source-address-prefixes VirtualNetwork
$ az network nsg rule create --name internal-from-lb \
--nsg-name internal-traffic --resource-group $RESOURCE_GROUP \
--protocol Tcp --priority 110 \
--destination-port-range *
--source-address-prefixes AzureLoadBalancer
```

11. Create a virtual network named `pcf-virtual-network`.

```
$ az network vnet create --name pcf-virtual-network \
--resource-group $RESOURCE_GROUP --location $LOCATION \
--address-prefixes 10.0.0/16
```

12. Add subnets to the network for Ops Manager, BOSH director, and the VMs for your runtime, and attach the Network Security Group.

```
$ az network vnet subnet create --name infrastructure \
--vnet-name pcf-virtual-network \
--resource-group $RESOURCE_GROUP \
--address-prefix 10.0.4.0/26 \
--network-security-group pcf-nsg
$ az network vnet subnet create --name pas \
--vnet-name pcf-virtual-network \
--resource-group $RESOURCE_GROUP \
--address-prefix 10.0.12.0/22 \
--network-security-group pcf-nsg
$ az network vnet subnet create --name services \
--vnet-name pcf-virtual-network \
--resource-group $RESOURCE_GROUP \
--address-prefix 10.0.8.0/22 \
--network-security-group pcf-nsg
```

Step 2: Create BOSH and Deployment Storage Accounts

PCF on Azure uses multiple general-purpose Azure storage accounts. The BOSH and Ops Manager VMs use one main BOSH account, and the other components share five or more deployment storage accounts.

To create storage accounts for BOSH and your deployment, do the following:

1. Choose a name for your BOSH storage account, and export it as the environment variable `STORAGE_NAME`. Storage account names must be globally unique across Azure, between 3 and 24 characters in length, and contain only lowercase letters and numbers.

```
$ export STORAGE_NAME="YOUR-BOSH-STORAGE-ACCOUNT-NAME"
```

2. Create a Standard storage account for BOSH with the following command. This account will be used for BOSH bookkeeping and running the Ops Manager VM itself, but does not have to be used for running any other VMs.

```
$ az storage account create --name $STORAGE_NAME \
--resource-group $RESOURCE_GROUP \
--sku Standard_LRS \
--location $LOCATION
```

 Note: `Standard_LRS` refers to a Standard Azure storage account. The BOSH Director requires table storage to store stemcell information. Azure Premium storage does not support table storage and cannot be used for the BOSH storage account.

If the command fails, ensure you have followed the rules for naming your storage account. Export another new storage account name if necessary.

3. Configure the Azure CLI to use the BOSH storage account as its default.

- a. Retrieve the connection string for the account.

```
$ az storage account show-connection-string \
--name $STORAGE NAME --resource-group $RESOURCE GROUP
```

The command returns output similar to the following:

```
{
  "connectionString": "DefaultEndpointsProtocol=https;EndpointSuffix=core.windows.net;AccountName=cfdocsboshstorage;AccountKey=EXAMPLEEaaaaabbbnrnc5igFxyWsgq016
```

- b. Record the full value of `connectionString` from the output above, starting with and including `DefaultEndpointsProtocol=`.
- c. Export the value of `connectionString` as the environment variable `$CONNECTION_STRING`.

```
$ export CONNECTION_STRING="YOUR-ACCOUNT-KEY-STRING"
```

4. Create three blob containers in the BOSH storage account, named `opsmanager`, `bosh`, and `stemcell`.

```
$ az storage container create --name opsmanager \
--connection-string $CONNECTION_STRING
$ az storage container create --name bosh \
--connection-string $CONNECTION_STRING
$ az storage container create --name stemcell --public-access blob \
--connection-string $CONNECTION_STRING
```

5. Create a table named `stemcells`.

```
$ az storage table create --name stemcells \
--connection-string $CONNECTION_STRING
```

6. Choose a set of unique names for five or more deployment storage accounts. As with the BOSH storage account above, the names must be unique, alphanumeric, lowercase, and 3-24 characters long. The account names must also be sequential or otherwise identical except for the last character. For example: `xyzdeploystorage1`, `xyzdeploystorage2`, `xyzdeploystorage3`, `xyzdeploystorage4`, and `xyzdeploystorage5`.

7. Decide which type of storage to use and run the corresponding command below.

Note: Pivotal recommends five Premium storage accounts, which provides a reasonable amount of initial storage capacity. You can use either Premium or Standard storage accounts, but they have very different scalability metrics. Pivotal recommends creating 1 Standard storage account for every 30 VMs, or 1 Premium storage account for every 150 VMs. You can increase the number of storage accounts later by provisioning more and following the naming sequence.

- To use Premium storage (recommended):

```
$ export STORAGE_TYPE="Premium_LRS"
```

- To use Standard storage:

```
$ export STORAGE_TYPE="Standard_LRS"
```

8. For each deployment storage account you create, do the following:

- a. Create the storage account with the following command, replacing `MY_DEPLOYMENT_STORAGE_X` with one of your deployment storage account names.

```
$ az storage account create --name MY_DEPLOYMENT_STORAGE_X \
--resource-group $RESOURCE_GROUP --sku $STORAGE_TYPE \
--kind Storage --location $LOCATION
```

If the command fails, try a different set of account names.

- b. Retrieve the connection string for the account.

```
$ az storage account show-connection-string \
--name MY_DEPLOYMENT_STORAGE_X --resource-group $RESOURCE_GROUP
```

The command returns output similar to the following:

```
{
  "connectionString": "DefaultEndpointsProtocol=https;EndpointSuffix=core.windows.net;AccountName=cfdoesdeploystorage1;AccountKey=EXAMPLEEaaaaaaQiSAmqj1OoesGh"
}
```

- c. Record the full value of `connectionString` from the output above, starting with and including `DefaultEndpointsProtocol=`.
- d. Create two blob containers named `bosh` and `stemcell` in the account.

```
$ az storage container create --name bosh \
--connection-string $CONNECTION_STRING
```

```
$ az storage container create --name stemcell \
--connection-string $CONNECTION_STRING
```

Step 3: Create Load Balancers

Your load balancer configuration depends on whether you want apps to be available from public IP addresses, private IP addresses, or both.

To create load balancers, do the following:

1. **Required:** PAS Load Balancer

- a. Create a load balancer named `pcf-lb`. A static IP address will be automatically created for Standard SKU load balancers unless specified otherwise with `--public-ip-address-allocation Dynamic`.

```
$ az network lb create --name pcf-lb \
--resource-group $RESOURCE_GROUP --location $LOCATION \
--backend-pool-name pcf-lb-be-pool --frontend-ip-name pcf-lb-fe-ip \
--public-ip-address pcf-lb-ip --public-ip-address-allocation Static \
--sku Standard
```

Note: If the Standard SKU is not available in Azure China, you can use the Basic SKU.

This back end pool is empty when you create it.

- b. Add a probe to the load balancer.

```
$ az network lb probe create --lb-name pcf-lb \
--name http8080 --resource-group $RESOURCE_GROUP \
--protocol Http --port 8080 --path \
```

- c. Add a load balancing rule for HTTP.

```
$ az network lb rule create --lb-name pcf-lb \
--name http --resource-group $RESOURCE_GROUP \
--protocol Tcp --frontend-port 80 \
--backend-port 80 --frontend-ip-name pcf-lb-fe-ip \
--backend-pool-name pcf-lb-be-pool \
--probe-name http8080
```

- d. Add a load balancing rule for HTTPS.

```
$ az network lb rule create --lb-name pcf-lb \
--name https --resource-group $RESOURCE_GROUP \
--protocol Tcp --frontend-port 443 \
--backend-port 443 --frontend-ip-name pcf-lb-fe-ip \
--backend-pool-name pcf-lb-be-pool \
--probe-name http8080
```

- e. (Optional) For private IPs, do the following:

- Create a load balancer named `pcf-lb`.

```
$ az network lb create --name pcf-lb \
--resource-group $RESOURCE_GROUP --location $LOCATION \
--backend-pool-name pcf-lb-be-pool --frontend-ip-name pcf-lb-fe-ip \
--private-ip-address 10.0.0.6 --sku Standard
```

- Add a probe to the load balancer.

```
$ az network lb probe create --lb-name pcf-lb \
--name http8080 --resource-group $RESOURCE_GROUP \
--protocol Http --port 8080
```

- Add a load balancing rule for HTTP.

```
$ az network lb rule create --lb-name pcf-lb \
--name http --resource-group $RESOURCE_GROUP \
--protocol Tcp --frontend-port 80 \
--backend-port 80 --frontend-ip-name pcf-lb-fe-ip \
--backend-pool-name pcf-lb-be-pool \
--probe-name http8080
```

- Add a load balancing rule for HTTPS.

```
$ az network lb rule create --lb-name pcf-lb \
--name https --resource-group $RESOURCE_GROUP \
--protocol Tcp --frontend-port 443 \
--backend-port 443 --frontend-ip-name pcf-lb-fe-ip \
--backend-pool-name pcf-lb-be-pool \
--probe-name http8080
```

Note: If the Standard SKU is not available in Azure China, you can use the Basic SKU.

This back end pool is empty when you create it.

- f. Navigate to your DNS provider and create an entry that points `*.YOUR-SUBDOMAIN` to the public IP address of your load balancer. For example, create an entry that points `azure.example.com` to `198.51.100.1`. You can retrieve it by running the following command:

```
az network public-ip show --name pcf-lb-ip --resource-group $RESOURCE_GROUP
```

2. Optional: Diego SSH Load Balancer

- a. Create a load balancer named `pcf-ssh-lb`.

```
$ az network lb create --name pcf-ssh-lb \
--resource-group $RESOURCE_GROUP --location $LOCATION \
--backend-pool-name pcf-ssh-lb-be-pool --frontend-ip-name pcf-ssh-lb-fe-ip \
--public-ip-address pcf-ssh-lb-ip --public-ip-address-allocation Static \
--sku Standard
```

 **Note:** If the Standard SKU is not available in Azure China, you can use the Basic SKU.

This back end pool is empty when you create it.

- b. (Optional) For private IPs, create a load balancer named `pcf-ssh-lb`.

```
$ az network lb create --name pcf-ssh-lb \
--resource-group $RESOURCE_GROUP --location $LOCATION \
--backend-pool-name pcf-ssh-lb-be-pool --frontend-ip-name pcf-ssh-lb-fe-ip \
--private-ip-address 10.0.0.7 \
--sku Standard
```

 **Note:** If the Standard SKU is not available in Azure China, you can change to use the Basic SKU.

This back end pool is empty when you create it.

- c. Add a probe to the load balancer.

```
$ az network lb probe create --lb-name pcf-ssh-lb \
--name tcp2222 --resource-group $RESOURCE_GROUP \
--protocol Tcp --port 2222
```

- d. Add a load balancing rule for SSH.

```
$ az network lb rule create --lb-name pcf-ssh-lb \
--name diego-ssh --resource-group $RESOURCE_GROUP \
--protocol Tcp --frontend-port 2222 \
--backend-port 2222 --frontend-ip-name pcf-ssh-lb-fe-ip \
--backend-pool-name pcf-ssh-lb-be-pool \
--probe-name tcp2222
```

- e. Navigate to your DNS provider, and create an entry that points `ssh.sys.YOUR-SUBDOMAIN` to the public IP address of your load balancer. For example, create an entry that points `azure.example.com` to `198.51.100.1`. You can retrieve it by running

```
az network public-ip show --name pcf-ssh-lb-ip --resource-group $RESOURCE_GROUP
```

Step 4: Boot Ops Manager

To boot Ops Manager, do the following:

1. Navigate to [Pivotal Network](#) and download the latest release of **Pivotal Cloud Foundry Ops Manager for Azure**.
2. View the downloaded PDF and locate the Ops Manager image URL appropriate for your region.
3. Export the Ops Manager image URL as an environment variable.

```
$ export OPS_MAN_IMAGE_URL="YOUR-OPS-MAN-IMAGE-URL"
```

4. Download the Ops Manager image. For compatibility when upgrading to future versions of Ops Manager, choose a unique name for the image that includes the Ops Manager version number. For example, replace `opsman-image-2.2.x` in the following examples with `opsman-image-2.2.1`.

- If you use unmanaged disks, perform the following steps:

 **Note:** Azure Stack requires unmanaged disks.

1. Download the Ops Manager image to your local machine. The image size is 10 GB.

```
$ wget $OPS_MAN_IMAGE_URL -O opsman-image-2.2.x.vhd
```

2. Upload the image to your storage account using the Azure CLI.

```
$ az storage blob upload --name opsman-image-2.2.x.vhd \
--connection-string $CONNECTION_STRING \
--container-name opsmanager \
--type page \
--file opsman-image-2.2.x.vhd
```

- o If you use managed disks, do the following:

1. Copy the Ops Manager image into your storage account using the Azure CLI.

```
$ az storage blob copy start --source-uri $OPS_MAN_IMAGE_URL \
--connection-string $CONNECTION_STRING \
--destination-container opsmanager \
--destination-blob opsman-image-2.2.x.vhd
```

2. Copying the image may take several minutes. Run the following command and examine the output under `"copy"`:

```
$ az storage blob show --name opsman-image-2.2.x.vhd \
--container-name opsmanager \
--connection-string $CONNECTION_STRING
...
"copy": {
  "completionTime": "2017-06-26T22:24:11+00:00",
  "id": "b9c8b272-a562-4574-baa6-f1a04afcefd1",
  "progress": "53687091712/53687091712",
  "source": "https://opsmanagerwestus.blob.core.windows.net/images/ops-manager-2.2.0.vhd",
  "status": "success",
  "statusDescription": null
},
```

3. Wait a few moments and re-run the command above if `status` is `pending`. When `status` reads `success`, continue to the next step.

5. Create a public IP address named `ops-manager-ip`.

```
$ az network public-ip create --name ops-manager-ip \
--resource-group $RESOURCE_GROUP --location $LOCATION \
--allocation-method Static
{
  "publicIp": {
    "dnsSettings": null,
    "etag": "W/4450ebc2-9e97-4b17-9ef2-44838339c661",
    "id": "/subscriptions/995b7eed-77cf-45ff-a5c9-1a405f1b8243/resourceGroups/cf-docs/providers/Microsoft.Network/publicIPAddresses/ops-manager-ip",
    "idleTimeoutInMinutes": 4,
    "ipAddress": "40.83.148.183",
    "ipConfiguration": null,
    "location": "westus",
    "name": "ops-manager-ip",
    "provisioningState": "Succeeded",
    "publicIpAddressVersion": "IPv4",
    "publicIpAllocationMethod": "Static",
    "resourceGroup": "cf-docs",
    "resourceGuid": "950d4831-1bec-42da-8a79-959becdea9dd",
    "tags": null,
    "type": "Microsoft.Network/publicIPAddresses"
  }
}
```

If you do not want to use a public IP for Ops Manager, skip this step.

6. Record the `ipAddress` from the output above. This is the public IP address of Ops Manager.
7. Create a network interface for Ops Manager.

```
$ az network nic create --vnet-name PCF \
--subnet infrastructure --network-security-group opsmgr-nsg \
--private-ip-address 10.0.4.4 \
--public-ip-address ops-manager-ip \
--resource-group $RESOURCE_GROUP \
--name opsman-nic --location $LOCATION
```

If you do not want use a public IP address for Ops Manager, remove the `--public-ip-address ops-manager-ip` flag and value.

8. Create a keypair on your local machine with the username `ubuntu`. For example, enter the following command:

```
$ ssh-keygen -t rsa -f opsman -C ubuntu
```

When prompted for a passphrase, press the `enter` key to provide an empty passphrase.

9. Create the Ops Manager VM.

- If you are using unmanaged disks, run the following command to create your Ops Manager VM, replacing `PATH-TO-PUBLIC-KEY` with the path to your public key `.pub` file:

```
$ az vm create --name opsman-2.2.x --resource-group $RESOURCE_GROUP \
--location $LOCATION \
--nics opsman-nic \
--image https://$STORAGE_NAME.my-azure-instance.com/opsmanager/opsman-image-2.2.x.vhd \
--os-disk-name opsman-2.2.x-osdisk \
--os-disk-size-gb 128 \
--os-type Linux \
--use-unmanaged-disk \
--storage-account $STORAGE_NAME \
--storage-container-name opsmanager \
--admin-username ubuntu \
--ssh-key-value PATH-TO-PUBLIC-KEY
```

Replace `my-azure-instance.com` with the URL of your Azure instance. Find the complete source URL in the Azure UI by viewing the **Blob properties** of the Ops Manager image you created earlier in this procedure.

- If you are using Azure managed disks, do the following:

1. Create a managed image from the Ops Manager VHD file:

```
$ az image create --resource-group $RESOURCE_GROUP \
--name opsman-image-2.2.x \
--source https://$STORAGE_NAME.blob.core.windows.net/opsmanager/image-2.2.x.vhd \
--location $LOCATION \
--os-type Linux
```

If you are using Azure China, Azure Government Cloud, or Azure Germany, replace `blob.core.windows.net` with the following:

- For Azure China, use `blob.core.chinacloudapi.cn`. See the [Azure documentation](#) for more information.
- For Azure Government Cloud, use `blob.core.usgovcloudapi.net`. See the [Azure documentation](#) for more information.
- For Azure Germany, use `blob.core.cloudapi.de`. See the [Azure documentation](#) for more information.

2. Create your Ops Manager VM, replacing `PATH-TO-PUBLIC-KEY` with the path to your public key `.pub` file.

```
$ az vm create --name opsman-2.2.x --resource-group $RESOURCE_GROUP \
--location $LOCATION \
--nics opsman-nic \
--image opsman-image-2.2.x \
--os-disk-size-gb 128 \
--os-disk-name opsman-2.2.x-osdisk \
--admin-username ubuntu \
--size Standard_DS2_v2 \
--storage-sku Standard_LRS \
--ssh-key-value PATH-TO-PUBLIC-KEY
```

10. If you plan to install more than one tile in this Ops Manager installation, do the following to increase the size of the Ops Manager VM disk. You can repeat this process and increase the disk again at a later time if necessary.

 **Note:** If you use Azure Stack, you must increase the Ops Manager VM disk size using the Azure Stack UI.

- a. Run the following command to stop the VM and detach the disk:

```
$ az vm deallocate --name opsman-2.2.x \
--resource-group $RESOURCE_GROUP
```

- b. Run the following command to resize the disk to 128 GB:

```
$ az disk update --size-gb 128 --name opsman-2.2.x-osdisk \  
--resource-group $RESOURCE_GROUP
```

- c. Run the following command to start the VM:

```
$ az vm start --name opsman-2.2.x --resource-group $RESOURCE_GROUP
```

Step 5: Complete BOSH Director Configuration

To finish configuring BOSH Director, do the following:

1. Navigate to your DNS provider, and create an entry that points a fully qualified domain name (FQDN) to the public IP address of Ops Manager. As a best practice, always use the FQDN to access Ops Manager.
2. Continue to [Configuring BOSH Director on Azure Manually](#).

Configuring BOSH Director on Azure Manually

Page last updated:

This topic describes how to configure the BOSH Director tile within Ops Manager on Azure after [Deploying Ops Manager on Azure Manually](#).

Prerequisites

See the following sections to prepare for configuring BOSH Director on Azure.

General Prerequisites

Before you perform the procedures in this topic, you must have completed the procedures in the following topics:

- [Preparing to Deploy Ops Manager on Azure Manually](#)
- [Deploying Ops Manager on Azure Manually](#)

Note: You can also perform the procedures in this topic using the Ops Manager API. For more information, see the [Using the Ops Manager API](#) topic.

Prerequisites for Azure Stack or Azure Government Cloud

If you are using Azure Stack or Azure Government Cloud, you must set custom VM types for a successful deployment. You can set custom VM types with the Ops Manager API. For more information, see [Using the Ops Manager API](#).

- **For Azure Stack:** The example below may not have up-to-date VM types. For a current list of supported Azure Stack VM types that you can include in your API call, see [Virtual Machine Sizes](#) from the Azure Stack documentation. Include at least one `Standard` VM type.

```
$ curl -k https://YOUR-OPS-MAN-FQDN/api/v0/vm_types -X
PUT -H "Authorization: bearer UAA-ACCESS-TOKEN"
"Content-Type: application/json" -d '{"vm_types":[
{"name":"Standard_DS1_v2","ram":3584,"cpu":1,"ephemeral_disk":51200},
{"name":"Standard_DS2_v2","ram":7168,"cpu":2,"ephemeral_disk":102400},
{"name":"Standard_DS3_v2","ram":14336,"cpu":4,"ephemeral_disk":204800},
{"name":"Standard_DS4_v2","ram":28672,"cpu":8,"ephemeral_disk":409600},
{"name":"Standard_DS5_v2","ram":57344,"cpu":8,"ephemeral_disk":819200},
{"name":"Standard_DS11_v2","ram":14336,"cpu":2,"ephemeral_disk":102400},
{"name":"Standard_DS12_v2","ram":28672,"cpu":4,"ephemeral_disk":204800},
{"name":"Standard_DS13_v2","ram":57344,"cpu":8,"ephemeral_disk":409600},
{"name":"Standard_DS14_v2","ram":114688,"cpu":16,"ephemeral_disk":819200}]}'
```

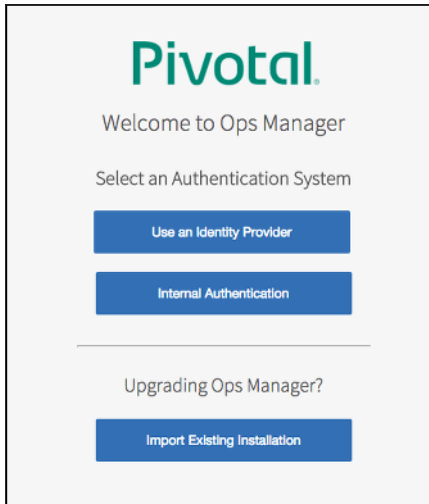

- **For Azure Government:** See the example `curl` command below for your list of VM types.

```
$ curl -k https://YOUR-OPS-MAN-FQDN/api/v0/vm_types -X
PUT -H "Authorization: bearer UAA-ACCESS-TOKEN"
"Content-Type: application/json" -d '{"vm_types":[
{"name": "Standard_D1_v2", "ram": 3584, "cpu": 1, "ephemeral_disk": 51200 },
{"name": "Standard_D2_v2", "ram": 7168, "cpu": 2, "ephemeral_disk": 102400 },
{"name": "Standard_D3_v2", "ram": 14336, "cpu": 4, "ephemeral_disk": 204800 },
{"name": "Standard_D4_v2", "ram": 28672, "cpu": 8, "ephemeral_disk": 409600 },
{"name": "Standard_D5_v2", "ram": 57344, "cpu": 8, "ephemeral_disk": 819200 },
{"name": "Standard_D11_v2", "ram": 14336, "cpu": 2, "ephemeral_disk": 102400 },
{"name": "Standard_D12_v2", "ram": 28672, "cpu": 4, "ephemeral_disk": 204800 },
{"name": "Standard_D13_v2", "ram": 57344, "cpu": 8, "ephemeral_disk": 409600 },
{"name": "Standard_D14_v2", "ram": 114688, "cpu": 16, "ephemeral_disk": 819200 },
{"name": "Standard_F1", "ram": 2048, "cpu": 1, "ephemeral_disk": 16384 },
{"name": "Standard_F2", "ram": 4096, "cpu": 2, "ephemeral_disk": 32768 },
{"name": "Standard_F4", "ram": 8192, "cpu": 4, "ephemeral_disk": 65536 },
{"name": "Standard_F8", "ram": 16384, "cpu": 8, "ephemeral_disk": 131072}]}'
```

To verify that you have successfully set your custom VM types, use the `GET /api/v0/vm_types` Ops Manager API endpoint.

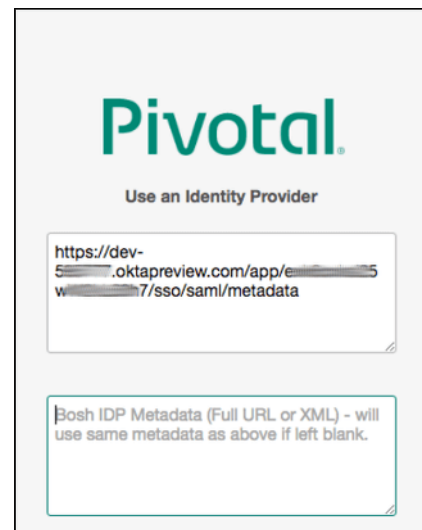

Step 1: Access Ops Manager

1. In a web browser, navigate to the fully qualified domain name (FQDN) of Ops Manager that you set up in either [Deploying BOSH and Ops Manager to Azure with ARM](#) or [Deploying Ops Manager on Azure Manually](#).
2. When Ops Manager starts for the first time, you must choose one of the following:
 - [Use an Identity Provider](#): If you use an Identity Provider, an external identity server maintains your user database.
 - [Internal Authentication](#): If you use Internal Authentication, Ops Manager maintains your user database.

Use an Identity Provider (IdP)

1. Log in to your IdP console and download the IdP metadata XML. Optionally, if your IdP supports metadata URL, you can copy the metadata URL instead of the XML.

2. Copy the IdP metadata XML or URL to the Ops Manager **Use an Identity Provider** login page.

Note: The same IdP metadata URL or XML is applied for the BOSH Director. If you use a separate IdP for BOSH, copy the metadata XML or URL from that IdP and enter it into the BOSH IdP Metadata text box in the Ops Manager login page.

3. Enter values for the fields listed below. Failure to provide values in these fields results in a 500 error.

Note: These attributes are case-sensitive.

- **SAML admin group:** Enter the name of the SAML group that contains all Ops Manager administrators.
- **SAML groups attribute:** Enter the groups attribute tag name with which you configured the SAML server.

4. Enter your **Decryption passphrase**. Read the **End User License Agreement**, and select the checkbox to accept the terms.
5. Your Ops Manager login page appears. Enter your username and password. Click **Login**.
6. Download your SAML Service Provider metadata (SAML Relying Party metadata) by navigating to the following URLs:

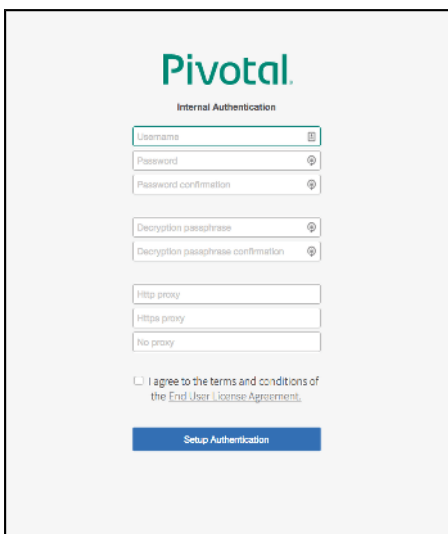

- **6a.** Ops Manager SAML service provider metadata: `https://OPS-MAN-FQDN:443/uaa/saml/metadata`
- **6b.** BOSH Director SAML service provider metadata: `https://BOSH-IP-ADDRESS:8443/saml/metadata`

 **Note:** To retrieve your `BOSH-IP-ADDRESS`, navigate to the **BOSH Director** tile > **Status** tab. Record the **BOSH Director** IP address.

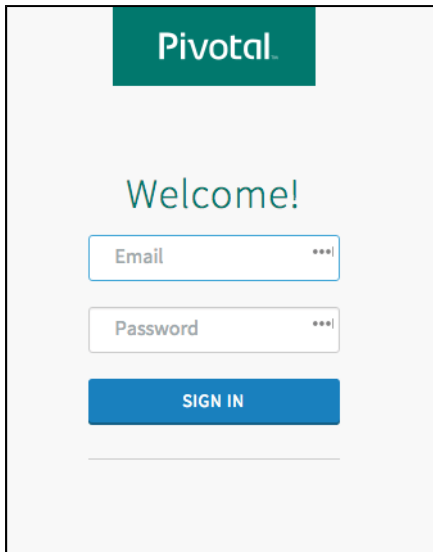

7. Configure your IdP with your SAML Service Provider metadata. Import the Ops Manager SAML provider metadata from Step 6a above to your IdP. If your IdP does not support importing, provide the values below.
 - **Single sign on URL:** `https://OPS-MAN-FQDN:443/uaa/saml/SSO/alias/OPS-MAN-FQDN`
 - **Audience URI (SP Entity ID):** `https://OP-MAN-FQDN:443/uaa`
 - **Name ID:** Email Address
 - SAML authentication requests are always signed
8. Import the BOSH Director SAML provider metadata from Step 6b to your IdP. If the IdP does not support an import, provide the values below.
 - **Single sign on URL:** `https://BOSH-IP:8443/saml/SSO/alias/BOSH-IP`
 - **Audience URI (SP Entity ID):** `https://BOSH-IP:8443`
 - **Name ID:** Email Address
 - SAML authentication requests are always signed
9. Return to the **BOSH Director** tile, and continue with the configuration steps below.

Internal Authentication

1. When redirected to the **Internal Authentication** page, do the following:
 - Enter a **Username**, **Password**, and **Password confirmation** to create an Admin user.
 - Enter a **Decryption passphrase** and the **Decryption passphrase confirmation**. This passphrase encrypts the Ops Manager datastore, and is not recoverable.
 - If you are using an **HTTP proxy** or **HTTPS proxy**, follow the instructions in [Configuring Proxy Settings for the BOSH CPI](#).
 - Read the **End User License Agreement**, and select the checkbox to accept the terms.
 - Click **Setup Authentication**.

2. Log in to Ops Manager with the Admin username and password that you created in the previous step.

A login form with a light gray background. At the top left is a dark teal rectangle with the word "Pivotal" in white. Below it, the word "Welcome!" is centered in a teal font. Underneath are two input fields: "Email" and "Password", both with placeholder text and a small "xxx|" icon on the right. Below the fields is a blue button with the text "SIGN IN" in white. A thin horizontal line is at the bottom.

Step 2: Azure Config Page

1. Click the **BOSH Director** tile.

2. Select **Azure Config**.

Installation Dashboard
Ops Manager Director

Settings Status Credentials

Azure Config

Director Config

Create Networks

Assign Networks

Security

Syslog

Resource Config

Subscription ID*

Tenant ID*

Application ID*

Client Secret*

Resource Group Name*

BOSH Storage Account Name*

Cloud Storage Type

☒ Use Managed Disks

Storage Account Type

Premium_LRS

☐ Use Storage Accounts

Deployments Storage Account Name

Default Security Group*

SSH Public Key*

SSH Private Key*

Save

- Complete the following fields with information you obtained in [Preparing to Deploy Ops Manager on Azure Manually](#).
 - Subscription ID:** Enter the ID of your Azure subscription.
 - Tenant ID:** Enter your `TENANT_ID`.
 - Application ID:** Enter the `APPLICATION_ID` that you created in the [Create an AAD Application](#) step of *Preparing to Deploy Ops Manager on Azure Manually*.
 - Client Secret:** Enter your `CLIENT_SECRET`.
- Complete the following fields:
 - Resource Group Name:** Enter the name of your resource group, which you exported as the `$RESOURCE_GROUP` environment variable.
 - BOSH Storage Account Name:** Enter the name of your storage account, which you exported as the `$STORAGE_NAME` environment variable.
- For **Cloud Storage Type**, select one of the following options based on your Azure VM storage settings.

- **Use Managed Disks:** Select this option if you use Azure Managed Disks. See [Azure Managed Disks Overview](#) in the Microsoft documentation for more information. For **Storage Account Type**, select the storage option that corresponds with your Azure subscription. Select **Standard_LRS** for HDD-based storage or **Premium_LRS** for SSD-based storage.

- **Use Storage Accounts:** Select this option if you use storage accounts to store your Azure VMs. Enter the base storage name that you used to create your deployment storage accounts, prepended and appended with the wildcard character `*`. For example, if you created accounts named `xyzdeploymentstorage1`, `xyzdeploymentstorage2`, and `xyzdeploymentstorage3`, enter `*deploymentstorage*`. Ops Manager requires that you specify an asterisk at both the beginning and the end of the base storage account name.

Warning: You can update your deployment from using storage accounts to using managed disks. However, after you select **Use Managed Disks** and deploy Ops Manager, you cannot change your deployment back to use storage accounts.

6. (Optional) Enter your **Default Security Group**. For more information about Network Security Groups, see [Filter network traffic with network security groups](#) in Microsoft Azure's documentation.

Note: The Azure portal sometimes displays the names of resources with incorrect capitalization. Always use the Azure CLI to retrieve the correctly capitalized name of a resource.

7. For **SSH Public Key**, copy and paste the contents of your public key in the `opsman.pub` file. You created this file in either [Deploying BOSH and Ops Manager to Azure with ARM](#) topic or [Deploying Ops Manager on Azure Manually](#).
8. For **SSH Private Key**, copy and paste the contents of your private key in the `opsman` file.
9. For **Azure Environment**, select the Azure cloud you want to use. Pivotal recommends **Azure Commercial Cloud** for most Azure environments.

Note: If you selected Azure Stack or Azure Government Cloud as your Azure environment, you must set custom VM types. For more information, see [Prerequisites for Azure Stack or Azure Government Cloud](#) in *Configuring BOSH Director on Azure Manually*.

10. (Optional) If you selected `Azure Stack` for your **Azure Environment**, complete the following Azure Stack-only fields:
 - a. For **Domain**, enter the domain for your Azure Stack deployment. For example, `local.azurestack.external`.
 - b. Enter the **Tenant Management Resource Endpoint** from your AzureRM Environment Context. This URL changes with every ASDK installation.
 - c. Enter `AzureAD` for **Authentication**. If you want to use Azure China Cloud Active Directory for your authentication type, enter `AzureChinaCloudAD`.
 - d. Enter your **Azure Stack Endpoint Prefix**. For example, `management`.
 - e. Enter your **Azure Stack CA Certificate**. Azure Stack requires a custom CA certificate. Copy the certificate from your Azure Stack environment.
11. Click **Save**.

Step 3: Director Config Page

1. Select **Director Config**.

Director Config

NTP Servers (comma delimited)*

JMX Provider IP Address

Bosh HM Forwarder IP Address

☐ Enable VM Resurrector Plugin

☐ Enable Post Deploy Scripts

☐ Recreate all VMs

This will force BOSH to recreate all VMs on the next deploy. Persistent disk will be preserved

☐ Enable bosh deploy retries

This will attempt to re-deploy a failed deployment up to 5 times.

☐ Keep Unreachable Director VMs

- In the **NTP Servers (comma delimited)** field, enter a comma-separated list of valid NTP servers.

 **Note:** The NTP server configuration only updates after VM recreation. Ensure that you select the **Recreate all VMs** checkbox if you modify the value of this field.

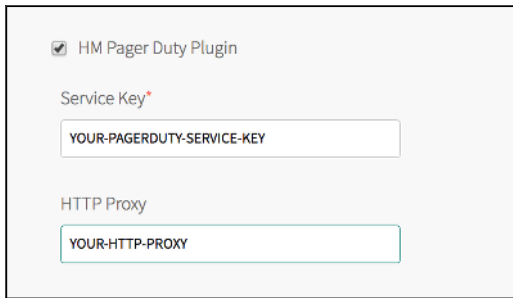

- Leave the **JMX Provider IP Address** field blank.

 **Note:** BOSH-reported component metrics are available in the Loggregator Firehose by default. Therefore, if you continue to use PCF JMX Bridge for consuming them outside of the Firehose, you may receive duplicate data. To prevent this, leave the **JMX Provider IP Address** field blank.

- Leave the **Bosh HM Forwarder IP Address** field blank.

 **Note:** BOSH-reported component metrics are available in the Loggregator Firehose by default. Therefore, if you continue to use the BOSH HM Forwarder for consuming them, you may receive duplicate data. To prevent this, leave the **Bosh HM Forwarder IP Address** field blank.

- Select the **Enable VM Resurrector Plugin** checkbox to enable the Ops Manager Resurrector functionality and increase PAS availability.
- Select **Enable Post Deploy Scripts** to run a post-deploy script after deployment. This script allows the job to execute additional commands against a deployment.
- Select **Recreate all VMs** to force BOSH to recreate all VMs on the next deploy. This process does not destroy any persistent disk data.
- Select **Enable bosh deploy retries** if you want Ops Manager to retry failed BOSH operations up to five times.
- (Optional) Disable **Allow Legacy Agents** if all of your tiles have stemcells v3468 or later. Disabling the field will allow Ops Manager to implement TLS secure communications.
- Select **Keep Unreachable Director VMs** if you want to preserve BOSH Director VMs after a failed deployment for troubleshooting purposes.
- (Optional) Select **HM Pager Duty Plugin** to enable Health Monitor integration with PagerDuty.

☒ HM Pager Duty Plugin

Service Key*

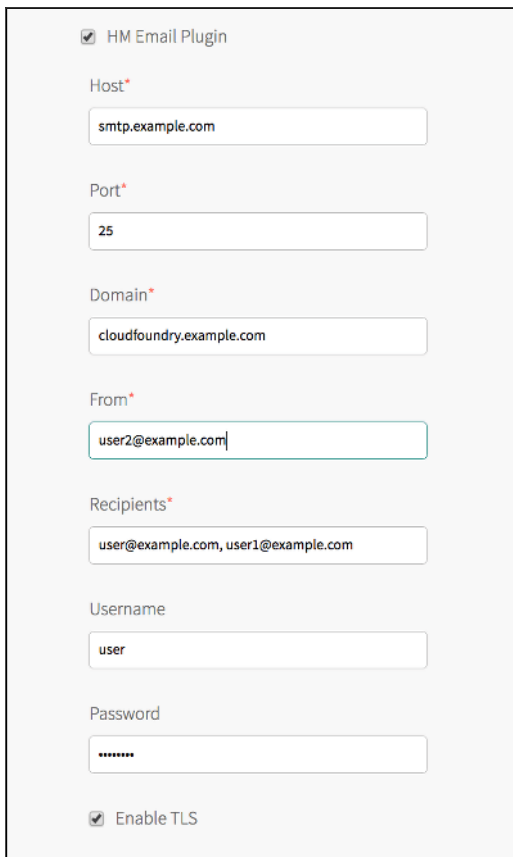

YOUR-PAGERDUTY-SERVICE-KEY

HTTP Proxy

YOUR-HTTP-PROXY

- **Service Key:** Enter your API service key from PagerDuty.
- **HTTP Proxy:** Enter an HTTP proxy for use with PagerDuty.

12. (Optional) Select **HM Email Plugin** to enable Health Monitor integration with email.

☒ HM Email Plugin

☒ Enable TLS

- **Host:** Enter your email hostname.
- **Port:** Enter your email port number.
- **Domain:** Enter your domain.
- **From:** Enter the address for the sender.
- **Recipients:** Enter comma-separated addresses of intended recipients.
- **Username:** Enter the username for your email server.
- **Password:** Enter the password for your email server.
- **Enable TLS:** Select this checkbox to enable Transport Layer Security.

13. For **CredHub Encryption Provider**, you can choose whether BOSH CredHub stores its encryption key internally on the BOSH Director and CredHub VM, or in an external hardware security module (HSM). The HSM option is more secure.

Before configuring an HSM encryption provider in the **Director Config** pane, you must follow the procedures and collect information described in [Preparing CredHub HSMs for Configuration](#).

 **Note:** After you deploy Ops Manager with an HSM encryption provider, you cannot change BOSH CredHub to store encryption keys internally.

CredHub Encryption Provider

☒ Internal
 ☐ Luna HSM

Encryption Key Name*

Provider Partition*

Provider Partition Password*

Provider Client Certificate*

Provider Client Certificate Private Key*

HSM Host Address*

HSM Port Address*

Partition Serial Number*

HSM Certificate*

- **Internal:** Select this option for internal CredHub key storage. This option is selected by default and requires no additional configuration.
- **Luna HSM:** Select this option to use a SafeNet Luna HSM as your permanent CredHub encryption provider, and fill in the following fields:
 1. **Encryption Key Name:** Any name to identify the key that the HSM uses to encrypt and decrypt the CredHub data. Changing this key name after you deploy Ops Manager can cause service downtime.
 2. **Provider Partition:** The partition that stores your encryption key. Changing this partition after you deploy Ops Manager could cause service downtime. For this value and the ones below, use values gathered in [Preparing CredHub HSMs for Configuration](#).
 3. **Provider Partition Password**
 4. **Provider Client Certificate:** The certificate that validates the identity of the HSM when CredHub connects as a client.
 5. **Provider Client Certificate Private Key**
 6. **HSM Host Address**
 7. **HSM Port Address:** If you do not know your port address, enter `1792`.
 8. **Partition Serial Number**
 9. **HSM Certificate:** The certificate that the HSM presents to CredHub to establish a two-way mTLS connection.

14. Select a **Blobstore Location** to either configure the blobstore as an internal server or an external endpoint. Because the internal server is unscalable and less secure, Pivotal recommends that you configure an external blobstore.

 **Note:** After you deploy Ops Manager, you cannot change the blobstore location.

Blobstore Location

☒ Internal

☐ S3 Compatible Blobstore

S3 Endpoint*

Bucket Name*

Access Key*

Secret Key*

☒ V2 Signature

☐ V4 Signature

Region*

☐ GCS Blobstore

Bucket Name*

Storage Class*

Regional

Service Account Key*

- o **Internal:** Select this option to use an internal blobstore. Ops Manager creates a new VM for blob storage. No additional configuration is required.
- o **S3 Compatible Blobstore:** Select this option to use an external S3-compatible endpoint. Follow the procedures in [Sign up for Amazon S3](#) and [Creating a Bucket](#) in the AWS documentation. When you have created an S3 bucket, complete the following steps:
 1. **S3 Endpoint:** Navigate to the [Regions and Endpoints](#) topic in the AWS documentation.
 - a. Locate the endpoint for your region in the **Amazon Simple Storage Service (S3)** table and construct a URL using your region's endpoint. For example, if you are using the `us-west-2` region, the URL you create would be `https://s3-us-west-2.amazonaws.com`. Enter this URL into the **S3 Endpoint** field.
 - b. On a command line, run `ssh ubuntu@OPS-MANAGER-FQDN` to SSH into the Ops Manager VM. Replace `OPS-MANAGER-FQDN` with the fully qualified domain name of Ops Manager.
 - c. Copy the custom public CA certificate you used to sign the S3 endpoint into `/etc/ssl/certs` on the Ops Manager VM.
 - d. On the Ops Manager VM, run `sudo update-ca-certificates -f -v` to import the custom CA certificate into the Ops Manager VM truststore.

 **Note:** You must also add this custom CA certificate into the **Trusted Certificates** field in the **Security** page. See [Security Page](#) for instructions.

2. **Bucket Name:** Enter the name of the S3 bucket.
3. **Access Key** and **Secret Key:** Enter the keys you generated when creating your S3 bucket.
4. Select **V2 Signature** or **V4 Signature**. If you select **V4 Signature**, enter your **Region**.

 **Note:** AWS recommends using Signature Version 4. For more information about AWS S3 Signatures, see [Authenticating Requests](#) in the AWS documentation.

- **Enable TLS:** Select this checkbox to enable TLS.

 **Note:** If you are using Linux stemcells, make sure you have configured [Linux stemcell v3586.16 or later](#) for all tiles before enabling TLS.

 **Note:** If you are using PAS for Windows 2016, make sure you have configured [Windows stemcell v1709.10 or later](#) for all tiles before enabling TLS.

- **GCS Blobstore:** Select this option to use an external GCS endpoint. To create a GCS bucket, you must have a GCS account. Follow the procedures in [Creating Storage Buckets](#) in the GCS documentation to create a GCS bucket. When you have created a GCS bucket, complete the following steps:
 1. **Bucket Name:** Enter the name of your GCS bucket.
 2. **Storage Class:** Select the storage class for your GCS bucket. See [Storage Classes](#) in the GCP documentation for more information.
 3. **Service Account Key:** Follow the steps in the [Set up an IAM Service Account](#) section of *Preparing to Deploy Ops Manager on GCP Manually* to download a JSON file with a private key. Enter the contents of the JSON file into the field.

Database Location

☒ Internal

☐ External MySQL Database

Host*

Port*

Username*

Password*

Database*

15. For **Database Location**, Pivotal recommends that you keep **Internal** selected. In addition, if you selected **External MySQL Database**, you can fill out the following optional fields:

- **Enable TLS:** Selecting this checkbox enables TLS communication between the BOSH Director and the database.
- **TLS CA:** Enter the Certificate Authority for the TLS Certificate.
- **TLS Certificate:** Enter the client certificate for mutual TLS connections to the database.
- **TLS Private Key:** Enter the client private key for mutual TLS connections to the database.
- **Advanced DB Connection Options:** If you would like to provide additional options for the database, use this field to provide a JSON-formatted options string.

 **Note:** You must select **Enable TLS for Director Database** to configure the TLS-related fields.

16. (Optional) **Director Workers** sets the number of workers available to execute Director tasks. This field defaults to `5`.
17. (Optional) **Max Threads** sets the maximum number of threads that the BOSH Director can run simultaneously. Pivotal recommends that you leave the field blank to use the default value unless doing so results in rate limiting or errors on your IaaS.
18. (Optional) To add a custom URL for your BOSH Director, enter a valid hostname in **Director Hostname**. You can also use this field to configure [a](#)

[load balancer in front of your BOSH Director](#).

⚠ warning: In Ops Manager v2.2.7 and earlier, if you change the **Director Hostname** after your initial deployment, VMs become unavailable. This causes downtime. To restore VM availability, enable **Recreate All VMs** and redeploy. This issue is resolved in [Ops Manager v2.2.8](#) and later.

Director Workers

Max Threads

Director Hostname

19. (Optional) Enter your list of comma-separated **Excluded Recursors** to declare which IP addresses and ports should not be used by the DNS server.
20. (Optional) To disable BOSH DNS, select the **Disable BOSH DNS server for troubleshooting purposes** checkbox. For more information about the BOSH DNS service discovery mechanism, see [BOSH DNS Enabled by Default](#) in the Ops Manager v2.2 Release Notes.

⚡ Breaking Change: Do not disable BOSH DNS without consulting Pivotal Support.

21. (Optional) To set a custom banner that users see when logging in to the Director using SSH, enter text in the **Custom SSH Banner** field.

☐ Disable BOSH DNS server for troubleshooting purposes

Custom SSH Banner

22. (Optional) Enter your comma-separated custom **Identification Tags**. For example, `iaas:foundation1, hello:world`. You can use the tags to identify your foundation when viewing VMs or disks from your IaaS.

💡 Note: Azure has limited space for identification tags. Pivotal recommends entering no more than five tags.

23. Click **Save**.

Step 4: Create Networks Page

In this procedure, you create three networks.

Create the Infrastructure Network

1. Select **Create Networks**.
2. Click **Add Network**.
3. Select **Enable ICMP checks** if you want to enable ICMP on your networks. Ops Manager uses ICMP checks to confirm that components within your network are reachable.

4. For **Name**, enter the name of the network you want to create. For example, `infrastructure`.

5. Under **Subnets**, complete the following fields:

- **Azure Network Name:** Enter `pcf-virtual-network/pcf-infrastructure-subnet`. You can use either the `NETWORK-NAME/SUBNET-NAME` format or the `RESOURCE-GROUP/NETWORK-NAME/SUBNET-NAME` format. If you specify a resource group, it must exist under the same subscription ID you provided in the [Azure Config Page](#).

 **Note:** The Azure portal sometimes displays the names of resources with incorrect capitalization. Always use the Azure CLI to retrieve the correctly capitalized name of a resource.

- **CIDR:** Enter `10.0.4.0/26`.
- **Reserved IP Ranges:** Enter the first nine IP addresses of the subnet. For example, `10.0.4.1-10.0.4.9`.
- **DNS:** Enter `168.63.129.16`.
- **Gateway:** Enter the first IP address of the subnet. For example, `10.0.4.1`.

Create Networks

Warning: Pivotal recommends keeping the IP settings throughout the life of your installation. Ops Manager may prevent you from changing them in the future.
Contact Pivotal support for help completing such a change.

Verification Settings

☐ Enable ICMP checks

Networks

[Add Network](#)

One or many IP ranges upon which your products will be deployed

▼ infrastructure 

Name*

infrastructure

Subnets

[Add Subnet](#)

Azure Network Name*

pcf-virtual-network/pcf-infrastructure-subn

CIDR*

10.0.4.0/26

Reserved IP Ranges

10.0.4.1-10.0.4.9

DNS*

168.63.129.16

Gateway*

10.0.4.1

6. Click **Save**.

 **Note:** After you deploy Ops Manager, you add subnets with overlapping Availability Zones to expand your network. For more information about configuring additional subnets, see [Expanding Your Network with Additional Subnets](#).

Create the Deployment Network

1. Click **Add Network**.
2. Select **Enable ICMP checks** if you want to enable ICMP on your networks. Ops Manager uses ICMP checks to confirm that components within your network are reachable.
3. For **Name**, enter the name of the network you want to create. For example, `pas`.
4. Under **Subnets**, complete the following fields:

- **Azure Network Name:** Enter `pcf-virtual-network/pcf-pas-subnet`. You can use either the `NETWORK-NAME/SUBNET-NAME` format or the `RESOURCE-GROUP/NETWORK-NAME/SUBNET-NAME` format. If you specify a resource group, it must exist under the same subscription ID you provided in the [Azure Config Page](#).

Note: The Azure portal sometimes displays the names of resources with incorrect capitalization. Always use the Azure CLI to retrieve the correctly capitalized name of a resource.

- **CIDR:** Enter `10.0.12.0/22`.
- **Reserved IP Ranges:** Enter the first nine IP addresses of the subnet. For example, `10.0.12.1-10.0.12.9`.
- **DNS:** Enter `168.63.129.16`.
- **Gateway:** Enter the first IP address of the subnet. For example, `10.0.12.1`.

The screenshot shows the 'Add Subnet' form in the Azure portal. The form is titled 'pas' and contains the following fields and values:

- Name:** pas
- Subnets:** (Section header)
- Azure Network Name:** pcf-virtual-network/pcf-pas-subnet
- CIDR:** 10.0.12.0/22
- Reserved IP Ranges:** 10.0.12.1-10.0.12.9
- DNS:** 168.63.129.16
- Gateway:** 10.0.12.1

An 'Add Subnet' button is located on the right side of the form.

5. Click **Save**.

Create the Services Network

1. Click **Add Network**.
2. Select **Enable ICMP checks** if you want to enable ICMP on your networks. Ops Manager uses ICMP checks to confirm that components within your network are reachable.
3. For **Name**, enter the name of the network you want to create. For example, `services`.
4. Under **Subnets**, complete the following fields:

- **Azure Network Name:** Enter `pcf-virtual-network/pcf-services-subnet`. You can use either the `NETWORK-NAME/SUBNET-NAME` format or the `RESOURCE-GROUP/NETWORK-NAME/SUBNET-NAME` format. If you specify a resource group, it must exist under the same subscription ID you provided in the [Azure Config Page](#).

Note: The Azure portal sometimes displays the names of resources with incorrect capitalization. Always use the Azure CLI to retrieve the correctly capitalized name of a resource.

- o **CIDR:** Enter `10.0.8.0/22`.
- o **Reserved IP Ranges:** Enter the first nine IP addresses of the subnet. For example, `10.0.8.1-10.0.8.9`.
- o **DNS:** Enter `168.63.129.16`.
- o **Gateway:** Enter the first IP address of the subnet. For example, `10.0.8.1`.

▼ services

Name*

pcf-virtual-network/pcf-services-subnet

CIDR*

10.0.8.0/22

Reserved IP Ranges

10.0.8.1-10.0.8.9

DNS*

168.63.129.16

Gateway*

10.0.8.1

5. Click **Save**. If you do not have **Enable ICMP checks** selected, you may see red warnings which you can safely ignore.

Step 5: Assign Networks Page

1. Select **Assign Networks**.

Network Assignments

Network

infrastructure

Save

2. Under **Network**, select the `infrastructure` network that you created from the dropdown.
3. Click **Save**.

Step 6: Security Page

Security

Trusted Certificates

-----BEGIN CERTIFICATE-----
TH[REDACTED]
[REDACTED]
[REDACTED]
[REDACTED]

These certificates enable BOSH-deployed components to trust a custom root certificate.

Generate VM passwords or use single password for all VMs

- ☒ Generate passwords
- ☐ Use default BOSH password

Save

1. Select **Security**.
2. In **Trusted Certificates**, enter your custom certificate authority (CA) certificates to insert into your organization's certificate trust chain. This feature enables all BOSH-deployed components in your deployment to trust custom root certificates.

To enter multiple certificates, paste your certificates one after the other. For example, format your certificates like the following:

```

-----BEGIN CERTIFICATE-----
ABCEDEFGH12345678ABCEDEFGH12345678ABCEDEFGH12345678AB
EFGH12345678ABCEDEFGH12345678ABCEDEFGH12345678ABCEDEF
GH12345678ABCEDEFGH12345678ABCEDEFGH12345678...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
BCDEFGH12345678ABCEDEFGH12345678ABCEDEFGH12345678ABB
EFGH12345678ABCEDEFGH12345678ABCEDEFGH12345678ABCEDEF
GH12345678ABCEDEFGH12345678ABCEDEFGH12345678...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
CDEFGH12345678ABCEDEFGH12345678ABCEDEFGH12345678ABBB
EFGH12345678ABCEDEFGH12345678ABCEDEFGH12345678ABCEDEF
GH12345678ABCEDEFGH12345678ABCEDEFGH12345678...
-----END CERTIFICATE-----

```

 Note: If you want to use Docker Registries for running app instances in Docker containers, enter the certificate for your private Docker Registry in this field. See [Using Docker Registries](#) for more information on running app instances in PAS using Docker Registries.

3. Choose **Generate passwords** or **Use default BOSH password**. Pivotal recommends that you use the **Generate passwords** option for greater security.
4. Click **Save**. To view your saved Director password, click the **Credentials** tab.

Step 7: Syslog Page

1. Select **Syslog**.

Syslog

Do you want to configure Syslog for Bosh Director?

☐ No
 ☒ Yes

Address*

The address or host for the syslog server

Port*

Transport Protocol*

TCP

☐ Enable TLS

Permitted Peer*

SSL Certificate*

Save

- (Optional) Select **Yes** to send BOSH Director system logs to a remote server.
- In the **Address** field, enter the IP address or DNS name for the remote server.
- In the **Port** field, enter the port number that the remote server listens on.
- In the **Transport Protocol** dropdown menu, select **TCP**, **UDP**, or **REL**. This selection determines which transport protocol is used to send the logs to the remote server.
- (Optional) Pivotal strongly recommends that you enable TLS encryption when forwarding logs as they may contain sensitive information. For example, these logs may contain cloud provider credentials. To enable TLS, perform the following steps.
 - In the **Permitted Peer** field, enter either the name or SHA1 fingerprint of the remote peer.
 - In the **SSL Certificate** field, enter the SSL certificate for the remote server.
- Click **Save**.

Step 8: Resource Config Page

- Select **Resource Config**.

Resource Config

| JOB | INSTANCES | PERSISTENT DISK TYPE | VM TYPE | LOAD BALANCERS | INTERNET CONNECTED |
|------------------------|--------------|----------------------|---|----------------|--------------------------|
| Ops Manager Director | Automatic: 1 | Automatic: 50 GB | Automatic: Standard_DS2_v2 (cpu: 2, ram | | <input type="checkbox"/> |
| Master Compilation Job | Automatic: 4 | None | Automatic: Standard_F4s (cpu: 4, ram: 8 G | | <input type="checkbox"/> |

Save

2. Ensure that the **Internet Connected** checkboxes are deselected for all jobs.
3. Adjust any values as necessary for your deployment. Under the **Instances**, **Persistent Disk Type**, and **VM Type** fields, choose **Automatic** from the dropdown to allocate the recommended resources for the job. If the **Persistent Disk Type** field reads **None**, the job does not require persistent disk space.

 **Note:** Ops Manager requires a Director VM with at least 8 GB memory.

 **Note:** If you set a field to **Automatic** and the recommended resource allocation changes in a future version, Ops Manager automatically uses the updated recommended allocation.

 **Note:** If you install PAS for Windows, provision your **Master Compilation Job** with at least 100 GB of disk space.

4. (Optional) For **Load Balancers**, enter your Azure application gateway name for each associated job. To create an application gateway, follow the procedures in [Configure an application gateway for SSL offload by using Azure Resource Manager](#) from the Azure documentation. When you create the application gateway, associate the gateway's IP address with your system domain.

 **warning:** This feature is not recommended for production use. The Azure load balancer does not support an override port in the healthcheck configuration.

5. Click **Save**.

Step 9: (Optional) Add Custom VM Extensions

Use the Ops Manager API to add custom properties to your VMs such as associated security groups and load balancers. For more information, see [Managing Custom VM Extensions](#).

Step 10: Complete the BOSH Director Installation

1. Click **Apply Changes**. If a red ICMP error message appears and you have disabled ICMP, click **Ignore errors and start the install**.
2. BOSH Director installs. This may take a few moments. When the installation process successfully completes, the **Changes Applied** window appears.
3. Click the **Installation Dashboard** link to return to the Installation Dashboard.

Next Steps

- (Optional) When Ops Manager finishes deploying, deploy BOSH Add-ons to your system. For more information, see [Deploying BOSH Add-Ons](#).
- Install one or more PCF runtime environments to complete your installation. For more information, see [Installing Runtimes](#).

Deploying PAS on Azure

Page last updated:

This topic describes how to install and configure Pivotal Application Service (PAS) on Azure.

Before you perform the procedures in this topic, you must have completed the procedures in the following topics:

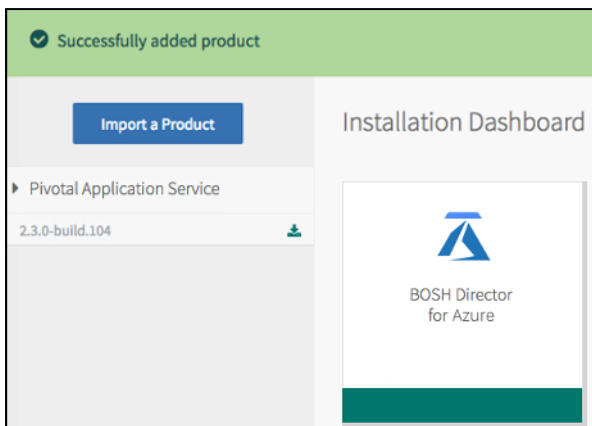

1. [Preparing to Deploy Ops Manager on Azure Manually](#)
2. [Deploying Ops Manager on Azure Manually](#)
3. [Configuring BOSH Director on Azure Manually](#)

Note: If you plan to [install the PCF IPsec add-on](#), you must do so before installing any other tiles. Pivotal recommends installing IPsec immediately after Ops Manager, and before installing the Pivotal Application Service (PAS) tile.

Note: The Azure portal sometimes displays the names of resources with incorrect capitalization. Always use the Azure CLI to retrieve the correctly capitalized name of a resource.

Step 1: Add PAS to Ops Manager

1. If you have not already downloaded PAS, log in to [Pivotal Network](#), and click on PAS.
2. From the **Releases** drop-down, select the release to install and choose one of the following:
 - a. Click PAS to download the PAS `.pivotal` file.
 - b. Click **PCF Small Footprint PAS** to download the Small Footprint Runtime `.pivotal` file. For more information, see [Getting Started with Small Footprint Runtime](#).
3. Navigate to the Ops Manager Installation Dashboard.
4. Click **Import a Product** and select the downloaded `.pivotal` file. For more information, refer to the [Adding and Deleting Products](#) topic.
5. Click the plus button next to the imported tile to add it to the Installation Dashboard.

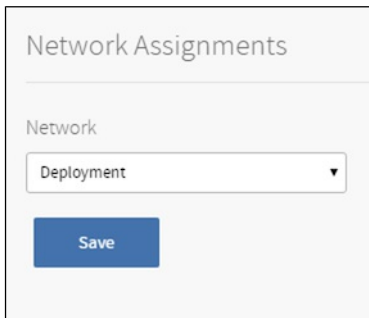

6. Click the PAS tile in the Installation Dashboard.

Step 2: Assign Networks

1. Select **Assign Networks**.
2. From the **Network** dropdown, select the network on which you want to run PAS.

Network Assignments

Network

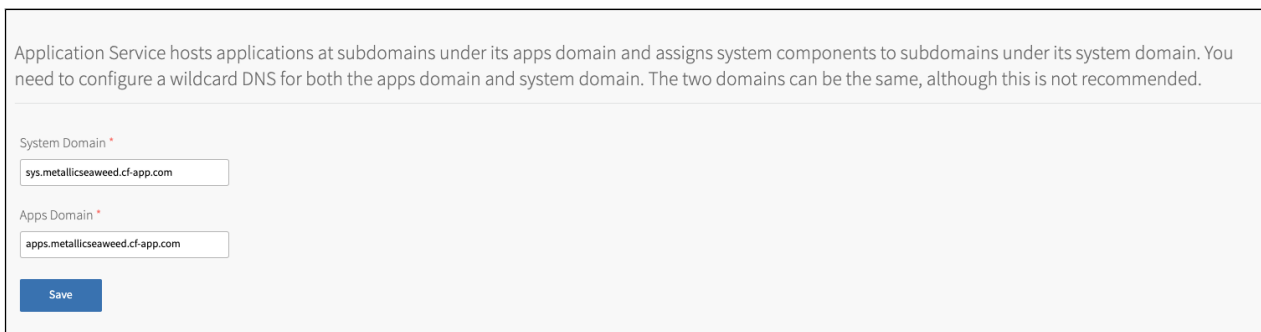

Deployment

Save

3. Click **Save**.

Step 3: Configure Domains

1. Select **Domains**.

Application Service hosts applications at subdomains under its apps domain and assigns system components to subdomains under its system domain. You need to configure a wildcard DNS for both the apps domain and system domain. The two domains can be the same, although this is not recommended.

System Domain *

sys.metallicseaweed.cf-app.com

Apps Domain *

apps.metallicseaweed.cf-app.com

Save

2. Enter the system and application domains.
 - The **System Domain** defines your target when you push apps to PAS. For example, `system.example.com`.
 - The **Apps Domain** defines where PAS should serve your apps. For example, `apps.example.com`.

Note: Pivotal recommends that you use the same domain name but different subdomain names for your system and app domains. Doing so allows you to use a single wildcard certificate for the domain while preventing apps from creating routes that overlap with system routes.

3. Navigate to your DNS provider to create A records that point from your wildcard system and apps domains to the public IP address of your load balancer. For example, if the IP address of your load balancer is 198.51.100.1, then create an A record that points `*.system.example.com` to that address and another A record that points `*.apps.example.com` to that address.

Note: To retrieve the IP address of your load balancer, navigate to the Azure portal, click **All resources**, and click the **Public IP address** resource that ends with `pcf-lb-ip`.

4. Click **Save**.

Step 4: Configure Networking

1. Select **Networking**.
2. Leave the **Router IPs**, **SSH Proxy IPs**, **HAProxy IPs**, and **TCP Router IPs** fields blank. You do not need to complete these fields when deploying PCF to Azure.

Note: You specify load balancers in the **Resource Config** section of PAS later on in the installation process. See the [Configuring Resources](#) section.

3. Under **Certificates and Private Key for HAProxy and Router**, you must provide at least one **Certificate and Private Key** name and certificate keypair for HAProxy and Gorouter. The HAProxy and Gorouter are enabled to receive TLS communication by default. You can configure multiple certificates for HAProxy and Gorouter.
 - a. Click the **Add** button to add a name for the certificate chain and its private keypair. This certificate is the default used by Gorouter and HAProxy.

Certificates and Private Keys for HAProxy and Router Add

▼ example-cert 🗑️

Name *

example-cert A human-readable name describing the use of this certificate.

Certificate and Private Key for HAProxy and Router *

```
-----BEGIN CERTIFICATE-----
MIIE...
-----END CERTIFICATE-----
-----BEGIN RSA PRIVATE KEY-----
...
-----END RSA PRIVATE KEY-----
```

[Generate RSA Certificate](#)

▼ example-cert-2 🗑️

Name *

example-cert-2

Certificate and Private Key for HAProxy and Router *

```
-----BEGIN CERTIFICATE-----
...
-----END CERTIFICATE-----
```

You can either provide a certificate signed by a Certificate Authority (CA) or click on the **Generate RSA Certificate** link to generate a self-signed certificate in Ops Manager.

- b. If you want to configure multiple certificates for HAProxy and Gorouter, click the **Add** button and fill in the appropriate fields for each additional certificate keypair.

For details about generating certificates in Ops Manager for your wildcard system domains, see the [Providing a Certificate for Your SSL/TLS Termination Point](#) topic.

Note: If you configured Ops Manager Front End without a certificate, you can use this new certificate to complete Ops Manager configuration. To configure your Ops Manager Front End certificate, see *Configure Front End* in [Preparing to Deploy Ops Manager on GCP Manually](#).

Note: Ensure that you add any certificates that you generate in this pane to your infrastructure load balancer.

4. (Optional) When validating client requests using mutual TLS, the Gorouter trusts multiple certificate authorities (CAs) by default. If you want to configure the Gorouter and HAProxy to trust additional CAs, enter your CA certificates under **Certificate Authorities Trusted by Router and HAProxy**. All CA certificates should be appended together into a single collection of PEM-encoded entries.

Certificate Authorities Trusted by Router and HAProxy

In addition to well-known, public CAs, and those trusted via the BOSH trusted certificates collection, these certificates can be used to validate the certificates from incoming client requests. All CA certificates should be appended together into a single collection of PEM-encoded entries.

- In the **Minimum version of TLS supported by HAProxy and Router** field, select the minimum version of TLS to use in HAProxy and Gorouter communications. HAProxy and Gorouter use TLS v1.2 by default. If you need to accommodate clients that use an older version of TLS, select a lower minimum version. For a list of TLS ciphers supported by the Gorouter, see [Securing Traffic into Cloud Foundry](#).

Minimum version of TLS supported by HAProxy and Router*

- ☐ TLSv1.0
- ☐ TLSv1.1
- ☒ TLSv1.2

- Configure **Logging of Client IPs in CF Router**. The **Log client IPs** option is set by default. To comply with the General Data Protection Regulation (GDPR), select one of the following options to disable logging of client IP addresses:

- If your load balancer exposes its own source IP address, disable logging of the `X-Forwarded-For` HTTP header only.
- If your load balancer exposes the source IP of the originating client, disable logging of both the source IP address and the `X-Forwarded-For` HTTP header.

Logging of Client IPs in CF Router*

- ☒ Log client IPs
- ☐ Disable logging of X-Forwarded-For header only
- ☐ Disable logging of both source IP and X-Forwarded-For header
- To comply with GDPR, select one of the options to disable logging of client IPs. If the source IP exposed by your load balancer is its own, choose to disable logging of XFF header only. If the source IP exposed by your load balancer is that of the downstream client, choose to disable logging of the source IP also.

- Under **Configure support for the X-Forwarded-Client-Cert header**, configure PCF handles `x-forwarded-client-cert` (XFCC) HTTP headers based on where TLS is terminated for the first time in your deployment.

Configure support for the X-Forwarded-Client-Cert header. This header can be used by applications to verify the requester via mutual TLS. The option you should select depends upon where you will be terminating the TLS connection for the first time. *

- ☒ TLS terminated for the first time at infrastructure load balancer
- ☐ TLS terminated for the first time at HAProxy
- ☐ TLS terminated for the first time at the Router

The following table

indicates which option to choose based on your deployment layout.

| If your deployment is configured as follows: | Then select the following option: | Additional notes: |
|--|--|---|
| <ul style="list-style-type: none"> The Load Balancer is terminating TLS, and Load balancer is configured to put the client certificate from a mutual authentication TLS handshake into the X-Forwarded-Client-Cert HTTP header | TLS terminated for the first time at infrastructure load balancer (default). | Both HAProxy and the Gorouter forward the XFCC header when included in the request. |
| <ul style="list-style-type: none"> The Load Balancer is configured to pass through the TLS handshake via TCP to | TLS terminated for | HAProxy sets the XFCC header with the client certificate received in the TLS handshake. The Gorouter forwards the header. |

| | | |
|--|--|---|
| <ul style="list-style-type: none"> the instances of HAProxy, and HAProxy instance count is > 0 | the first time at HAProxy. |  Breaking Change: In the Router behavior for Client Certificates field, you cannot select the Router does not request client certificates option. |
| <ul style="list-style-type: none"> The Load Balancer is configured to pass through the TLS handshake via TCP to instances of the Gorouter | TLS terminated for the first time at the Gorouter. | <p>The Gorouter strips the XFCC header if it is included in the request and forwards the client certificate received in the TLS handshake in a new XFCC header.</p> <p>If you have deployed instances of HAProxy, app traffic bypasses those instances in this configuration. If you have also configured your load balancer to route requests for ssh directly to the Diego Brain, consider reducing HAProxy instances to 0.</p>  Breaking Change: In the Router behavior for Client Certificates field, you cannot select the Router does not request client certificates option. |

For a description of the behavior of each configuration option, see [Forward Client Certificate to Applications](#).

- To configure HAProxy to handle client certificates, select one of the following options in the **HAProxy behavior for Client Certificate Validation** field.

HAProxy behavior for Client Certificate Validation*

- ☒ HAProxy does not request client certificates.
- ☐ HAProxy requests but does not require client certificates. This option is necessary if you want to enable mTLS for applications and TLS is terminated for the first time at HAProxy

- HAProxy does not request client certificates.** This option requires mutual authentication, which makes it incompatible with XFCC option **TLS terminated for the first time at HAProxy**. HAProxy does not request client certificates, so the client does not provide them and no validation occurs. This is the default configuration.
- HAProxy requests but does not require client certificates.** The HAProxy requests client certificates in TLS handshakes, validates them when presented, but does not require them.

 **warning:** Upon upgrade, PAS will fail to receive requests if your load balancer is configured to present a client certificate in the TLS handshake with HAProxy but HAProxy has not been configured with the certificate authority used to sign it. To mitigate this issue, select **HAProxy does not request client certificates** in the **Networking** pane or configure the HAProxy with the appropriate CA.

- To configure Gorouter behavior for handling client certificates, select one of the following options in the **Router behavior for Client Certificate Validation** field.

Router behavior for Client Certificate Validation*

- ☐ Router does not request client certificates. This option is incompatible with XFCC options "TLS terminated for the first time at HAProxy" and "TLS terminated for the first time at the Router" because these options require mutual authentication.
- ☒ Router requests but does not require client certificates.
- ☐ Router requires client certificates.

- Router does not request client certificates.** This option is incompatible with the XFCC configuration options **TLS terminated for the first time at HAProxy** and **TLS terminated for the first time at the Router** in PAS because these options require mutual authentication. As client certificates are not requested, client will not provide them, and thus validation of client certificates will not occur.
- Router requests but does not require client certificates.** The Gorouter requests client certificates in TLS handshakes, validates them when presented, but does not require them. This is the default configuration.
- Router requires client certificates.** The Gorouter validates that the client certificate is signed by a Certificate Authority that the Gorouter trusts. If the Gorouter cannot validate the client certificate, the TLS handshake fails.

 **warning:** Requests to the platform will fail upon upgrade if your load balancer is configured with client certificates and the Gorouter does not have the certificate authority. To mitigate this issue, select **Router does not request client certificates** for **Router behavior for Client**

Certificate Validation in the Networking pane.

- In the **TLS Cipher Suites for Router** field, review the TLS cipher suites for TLS handshakes between Gorouter and front-end clients such as load balancers or HAProxy. The default value for this field is `ECDHE-RSA-AES128-GCM-SHA256:TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384`. If you want to modify the default configuration, use an ordered, colon-delimited list of Golang-supported TLS cipher suites in the OpenSSL format. Operators should verify that the ciphers are supported by any clients or front-end components that will initiate TLS handshakes with Gorouter. For a list of TLS ciphers supported by Gorouter, see [Securing Traffic into Cloud Foundry](#).

TLS Cipher Suites for Router *

ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384

Verify that every client participating in TLS handshakes with Gorouter has at least one cipher suite in common with Gorouter.

 **Note:** Specify cipher suites that are supported by the versions configured in the **Minimum version of TLS supported by HAProxy and Router** field.

- In the **TLS Cipher Suites for HAProxy** field, review the TLS cipher suites for TLS handshakes between HAProxy and its clients such as load balancers and Gorouter. The default value for this field is the following:
`DHE-RSA-AES128-GCM-SHA256:DHE-RSA-AES256-GCM-SHA384:ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384` If you want to modify the default configuration, use an ordered, colon-delimited list of TLS cipher suites in the OpenSSL format. Operators should verify that the ciphers are supported by any clients or front-end components that will initiate TLS handshakes with HAProxy.

TLS Cipher Suites for HAProxy *

DHE-RSA-AES128-GCM-SHA256:DHE-RSA-AES256-GCM-SHA384:ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384

Verify that every client participating in TLS handshakes with HAProxy has at least one cipher suite in common with HAProxy.

 **Note:** Specify cipher suites that are supported by the versions configured in the **Minimum version of TLS supported by HAProxy and Router** field.

- Under **HAProxy forwards requests to Router over TLS**, select **Enable** or **Disable** based on your deployment layout.

HAProxy forwards requests to Router over TLS. When enabled, HAProxy will forward all requests to the Router over TLS. HAProxy will use the CA provided to verify the certificates provided by the Router. *

☒ Enable

Certificate Authority for HAProxy Backend *

You need to provide a certificate authority for the certificate and key provided in the "Certificate and Private Key for HAProxy and Router" field. HAProxy will verify those certificates using this CA when establishing a connection. If you generated that certificate and key using the "Generate RSA Certificate" feature, then your CA is the Ops Manager CA, and can be found by visiting the "/api/v0/certificate_authorities" API endpoint.

☐ Disable

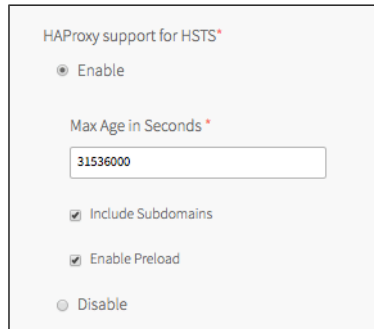

◦ Enable HAProxy forwarding of requests to Router over TLS

| If you want to: | Encrypt communication between HAProxy and the Gorouter |
|-------------------------------|---|
| Then configure the following: | <ol style="list-style-type: none"> 1. Leave Enable selected. 2. In the Certificate Authority for HAProxy Backend field, specify the Certificate Authority (CA) that signed the certificate you configured in the Certificate and Private Key for HAProxy and Router field. <div>  Note: If you used the Generate RSA Certificate link to generate a self-signed certificate, then the CA to specify is the Ops Manager CA, which you can locate at the <code>/api/v0/certificate_authorities</code> endpoint in the Ops Manager API. </div> <ol style="list-style-type: none"> 3. Make sure that Gorouter and HAProxy have TLS cipher suites in common in the TLS Cipher Suites for Router and TLS Cipher Suites for HAProxy fields. |
| See also: | <ul style="list-style-type: none"> ◦ Terminating SSL/TLS at the Load Balancer and Gorouter ◦ Providing a Certificate for Your SSL/TLS Termination Point ◦ Using the Ops Manager API |

◦ Disable HAProxy forwarding of requests to Router over TLS

| If you want to: | Use non-encrypted communication between HAProxy and Gorouter, or you are not using HAProxy |
|-------------------------------|---|
| Then configure the following: | <ol style="list-style-type: none"> 1. Select Disable. 2. If you are not using HAProxy, set the number of HAProxy job instances to <code>0</code> on the Resource Config page. See Disable Unused Resources. |
| See also: | <ul style="list-style-type: none"> ◦ Terminating SSL/TLS at the Gorouter Only ◦ Terminating SSL/TLS at the Load Balancer Only |

13. If you want to force browsers to use HTTPS when making requests to HAProxy, select **Enable** in the **HAProxy support for HSTS** field and complete

HAProxy support for HSTS*

☒ Enable

Max Age in Seconds*

31536000

☒ Include Subdomains

☒ Enable Preload

☐ Disable

the following optional configuration steps:

- (Optional) Enter a **Max Age in Seconds** for the HSTS request. By default, the age is set to one year. HAProxy will force HTTPS requests from browsers for the duration of this setting.
- (Optional) Select the **Include Subdomains** checkbox to force browsers to use HTTPS requests for all component subdomains.
- (Optional) Select the **Enable Preload** checkbox to force instances of Google Chrome, Firefox, and Safari that access your HAProxy to refer to their built-in lists of known hosts that require HTTPS, of which HAProxy is one. This ensures that the first contact a browser has with your HAProxy is an HTTPS request, even if the browser has not yet received an HSTS header from HAProxy.

- If you are not using SSL encryption or if you are using self-signed certificates, select **Disable SSL certificate verification for this environment**. Selecting this checkbox also disables SSL verification for route services.

 **Note:** For production deployments, Pivotal does not recommend disabling SSL certificate verification.

- (Optional) If you want HAProxy or the Gorouter to reject any HTTP (non-encrypted) traffic, select the **Disable HTTP on HAProxy and Gorouter** checkbox. When selected, HAProxy and Gorouter will not listen on port 80.

☐ Disable HTTP on HAProxy and Gorouter

- (Optional) Select the **Disable insecure cookies on the Router** checkbox to set the secure flag for cookies generated by the router.
- (Optional) To disable the addition of Zipkin tracing headers on the Gorouter, deselect the **Enable Zipkin tracing headers on the router** checkbox. Zipkin tracing headers are enabled by default. For more information about using Zipkin trace logging headers, see [Zipkin Tracing in HTTP Headers](#).
- (Optional) To stop the Router from writing access logs to local disk, deselect the **Enable Router to write access logs locally** checkbox. You should consider disabling this checkbox for high traffic deployments since logs may not be rotated fast enough and can fill up the disk.
- By default, the PAS routers handle traffic for applications deployed to an isolation segment created by the PCF Isolation Segment tile. To configure the PAS routers to reject requests for applications within isolation segments, select the **Routers reject requests for Isolation Segments** checkbox.

☐ Routers reject requests for Isolation Segments

Do not enable this option without deploying

routers for each isolation segment. See the following topics for more information:

- [Installing PCF Isolation Segment](#)
- [Sharding Routers for Isolation Segments](#)

- (Optional) By default, Gorouter support for the PROXY protocol is disabled. To enable the PROXY protocol, select **Enable support for PROXY protocol in CF Router**. When enabled, client-side load balancers that terminate TLS but do not support HTTP can pass along information from the originating client. Enabling this option may impact Gorouter performance. For more information about enabling the PROXY protocol in Gorouter, see the *HTTP Header Forwarding* sections in the [Securing Traffic in Cloud Foundry](#) topic.
- In the **Choose whether to enable route services** section, choose either **Enable route services** or **Disable route services**. Route services are a class of [marketplace services](#) that perform filtering or content transformation on application requests and responses. See the [Route Services](#) topic for details.
 - If you enabled route services, you can also configure the **Bypass security checks for route service lookup** field. Pivotal recommends that you do not enable this field because it has potential security concerns. However, you may need to enable it if your load balancer requires mutual TLS from clients. For more information, see [Configuring Route Service Lookup](#).
- (Optional) If you want to limit the number of app connections to the backend, enter a value in the **Max Connections Per Backend** field. You can use this field to prevent a poorly behaving app from all the connections and impacting other apps.

To choose a value for this field, review the peak concurrent connections received by instances of the most popular apps in your deployment. You can determine the number of concurrent connections for an app from the `httpStartStop` event metrics emitted for each app request.

If your deployment uses PCF Metrics, you can also obtain this peak concurrent connection information from [Network Metrics](#). The default value is

Max Connections Per Backend *

500

23. Under **Enable Keepalive Connections for Router**, select **Enable** or **Disable**. Keepalive connections are enabled by default. For more information, see [Keepalive Connections](#) in *HTTP Routing*.

Enable Keepalive Connections for Router *
☒ Enable
☐ Disable

24. (Optional) Increase the number of seconds in the **Router Timeout to Backends** field to accommodate larger uploads over connections with high latency. Set this value to less than or equal to the idle timeout value of the Azure load balancer, which defaults to 4 minutes.

 **Note:** If the router timeout value exceeds the Azure LB timeout, you may experience intermittent TCP resets. For more information about configuring Azure load balancer idle timeout, see the [Azure documentation](#).

25. (Optional) Use the **Frontend Idle Timeout for Gorouter and HAProxy** field to help prevent connections from your load balancer to Gorouter or HAProxy from being closed prematurely. The value you enter sets the duration, in seconds, that Gorouter or HAProxy maintains an idle open connection from a load balancer that supports keep-alive.

In general, set the value higher than your load balancer's backend idle timeout to avoid the race condition where the load balancer sends a request before it discovers that Gorouter or HAProxy has closed the connection.

See the following table for specific guidance and exceptions to this rule:

| IaaS | Guidance |
|-------|---|
| AWS | AWS ELB has a default timeout of 60 seconds, so Pivotal recommends a value greater than <code>60</code> . |
| Azure | By default, Azure load balancer times out at 240 seconds without sending a TCP RST to clients, so as an exception, Pivotal recommends a value lower than <code>240</code> to force the load balancer to send the TCP RST. |
| GCP | GCP has a default timeout of 600 seconds. For GCP HTTP load balancers, Pivotal recommends a value greater than <code>600</code> . For GCP TCP load balancers, Pivotal recommends a value less than <code>600</code> to force the load balancer to send a TCP RST. |
| Other | Set the timeout value to be greater than that of the load balancer's backend idle timeout. |

 **Note:** Do not set a frontend idle timeout lower than six seconds.

26. (Optional) Increase the value of **Load Balancer Unhealthy Threshold** to specify the amount of time, in seconds, that the router continues to accept connections before shutting down. During this period, healthchecks may report the router as unhealthy, which causes load balancers to failover to other routers. Set this value to an amount greater than or equal to the maximum time it takes your load balancer to consider a router instance unhealthy, given contiguous failed healthchecks.

27. (Optional) Modify the value of **Load Balancer Healthy Threshold**. This field specifies the amount of time, in seconds, to wait until declaring the Router instance started. This allows an external load balancer time to register the Router instance as healthy.

Load Balancer Unhealthy Threshold *

Load Balancer Healthy Threshold *

28. (Optional) If app developers in your organization want certain HTTP headers to appear in their app logs with information from the Gorouter, specify them in the **HTTP Headers to Log** field. For example, to support app developers that deploy Spring apps to PCF, you can enter [Spring-specific HTTP](#)

[headers](#) .

HTTP Headers to Log

29. If you expect requests larger than the default maximum of 16 Kbytes, enter a new value (in bytes) for **HAProxy Request Max Buffer Size**. You may need to do this, for example, to support apps that embed a large cookie or query string values in headers.

30. If your PCF deployment uses HAProxy and you want it to receive traffic only from specific sources, use the following fields:

- **HAProxy Protected Domains:** Enter a comma-separated list of domains to protect from unknown source requests.
- **HAProxy Trusted CIDRs:** Optionally, enter a space-separated list of CIDRs to limit which IP addresses from the **Protected Domains** can send traffic to PCF.

HAProxy Protected Domains

A comma-separated list of domains to protect from requests from unknown sources. Use this property in conjunction with "Trusted CIDRs" to protect these domains from requests from unknown sources.

HAProxy Trusted CIDRs

31. The **Loggregator Port** defaults to if left blank. Leave this field blank.

Container Network Interface Plugin*

 Silk

32. For **Container Network Interface Plugin**, ensure **Silk** is selected and review the following fields:

 **Note:** The **External** option exists to support NSX-T integration for vSphere deployments.

- (Optional) You can change the value in the **Applications Network Maximum Transmission Unit (MTU)** field. Pivotal recommends setting the MTU value for your application network to . Some configurations, such as networks that use GRE tunnels, may require a smaller MTU value.
- (Optional) Enter an IP range for the overlay network in the **Overlay Subnet** box. If you do not set a custom range, Ops Manager uses .

 **warning:** The overlay network IP range must not conflict with any other IP addresses in your network.

- Enter a UDP port number in the **VXLAN Tunnel Endpoint Port** box. If you do not set a custom port, Ops Manager uses 4789.
- For **Denied logging interval**, set the per-second rate limit for packets blocked by either a container-specific [networking policy](#) or by [Application Security Group](#) rules applied across the space, org, or deployment. This field defaults to .
- For **UDP logging interval**, set the per-second rate limit for UDP packets sent and received. This field defaults to .
- To enable logging for app traffic, select **Log traffic for all accepted/denied application packets**. See [Manage Logging for Container-to-Container Networking](#) for more information.
- By default, containers use the same DNS servers as the host. If you want to override the DNS servers to be used in containers, enter a comma-separated list of servers in **DNS Servers**.

 **Note:** If your deployment uses BOSH DNS, which is the default, you cannot use this field to override the DNS servers used in containers.

33. For **DNS Search Domains**, enter DNS search domains for your containers as a comma-separated list. DNS on your containers appends these names to its host names, to resolve them into full domain names.

DNS Search Domains

DNS search domains to be used in containers. A comma-separated list can be specified.

34. For **Database Connection Timeout**, set the connection timeout for clients of the policy server and silk databases. The default value is . You may

need to increase this value if your deployment experiences timeout issues related to Container-to-Container Networking.

35. (Optional) TCP Routing is disabled by default. You should enable this feature if your DNS sends TCP traffic through a load balancer rather than directly to a TCP router. To enable TCP routing:

- a. Select **Enable TCP Routing**.
- b. For **TCP Routing Ports**, enter a single port or a range of ports for the load balancer to forward to. These are the same ports that you configured in the [Pre-Deployment Steps](#) of the *Enabling TCP Routing* topic.
 - To support multiple TCP routes, Pivotal recommends allocating multiple ports.
 - To allocate a list of ports rather than a range:
 1. Enter a single port in the **TCP Routing Ports** field.
 2. After deploying PAS, follow the directions in [Configuring a List of TCP Routing Ports](#) to add TCP routing ports using the cf CLI.

Enable TCP requests to your apps via specific ports on the TCP router. You will want to configure a load balancer to forward these TCP requests to the TCP routers. If you do not have a load balancer, then you can also send traffic directly to the TCP router.*

☐ Select this option if you prefer to enable TCP Routing at a later time
☒ **Enable TCP Routing**

TCP Routing Ports (one-time configuration, if you want to update this value you can via the CF CLI) *

1024-1123

- c. For Azure, you also need to specify the name of Azure load balancer in the LOAD BALANCER column of TCP Router job of the **Resource Config** screen. You configure this later on in PAS. See [Configuring Resources](#).

36. (Optional) To disable TCP routing, click **Select this option if you prefer to enable TCP Routing at a later time** For more information, see the [Configuring TCP Routing in PAS](#) [↗](#) topic.

37. Click **Save**.

Step 5: Configure Application Containers

1. Select **Application Containers**.

Enable microservice frameworks, private Docker registries, and other services that support your applications at a container level.

- ☒ Enable Custom Buildpacks
- ☒ Allow SSH access to app containers
- ☒ Enable SSH when an app is created
- ☒ Enable the GrootFS container image plugin for Garden RunC

☐ Router uses TLS to verify application identity

Private Docker Insecure Registry Whitelist

10.10.10.10:8888,example.com:8888

Docker Images Disk-Cleanup Scheduling on Cell VMs*

- ☐ Never clean up Cell disk-space
- ☐ Routinely clean up Cell disk-space
- ☒ Clean up disk-space once threshold is reached

Threshold of Disk-Used (MB) (min: 1) *

10240

- The **Enable Custom Buildpacks** checkbox governs the ability to pass a custom buildpack URL to the `-b` option of the `cf push` command. By default, this ability is enabled, letting developers use custom buildpacks when deploying apps. Disable this option by disabling the checkbox. For more information about custom buildpacks, refer to the [buildpacks](#) section of the PCF documentation.
- The **Allow SSH access to app containers** checkbox controls SSH access to application instances. Enable the checkbox to permit SSH access across your deployment, and disable it to prevent all SSH access. See the [Application SSH Overview](#) topic for information about SSH access permissions at the space and app scope.
- If you want to enable SSH access for new apps by default in spaces that allow SSH, select **Enable SSH when an app is created**. If you deselect the checkbox, developers can still enable SSH after pushing their apps by running `cf enable-ssh APP-NAME`.
- If you want to disable the Garden Root filesystem (GrootFS), deselect the **Enable the GrootFS container image plugin for Garden RunC** checkbox. Pivotal recommends using this plugin, so it is enabled by default. However, some external components are sensitive to dependencies with filesystems such as GrootFS. If you experience issues, such as antivirus or firewall compatibility problems, deselect the checkbox to roll back to the plugin that is built into Garden RunC. For more information about GrootFS, see [Component: Garden](#) and [Container Mechanics](#).

 **Note:** If you modify this setting, Pivotal recommends recreating all VMs in the BOSH Director config. You can do this by selecting the **Recreate all VMs** checkbox in the **Director Config** pane of the BOSH Director tile before you redeploy.

- To enable Gorouter to verify app identity using TLS, select the **Router uses TLS to verify application identity** checkbox.

Verifying app identity using TLS enables encryption between router and app containers and guards against misrouting during control plane failures. For more information about Gorouter route consistency modes, see [Preventing Misrouting](#) in *HTTP Routing*.

 **warning:** TLS routing requires an additional 32 MB of RAM capacity on Diego cells per app instance. It also requires additional CPU capacity on Diego cells. If the total amount of Diego cell memory available is less than 32 MB times the number of running app instances, scale your Diego cells before configuring the Gorouter with TLS.

 **Warning:** You may see an increase of memory and CPU usage for your Gorouters after enabling TLS routing. If the total amount of memory and CPU usage of the Gorouters in your environment are close to the size limit, scale your Gorouters before enabling TLS routing.

7. You can configure Pivotal Application Service (PAS) to run app instances in Docker containers by supplying their IP address ranges in the **Private Docker Insecure Registry Whitelist** textbox. See the [Using Docker Registries](#) topic for more information.
8. Select your preference for **Docker Images Disk-Cleanup Scheduling on Cell VMs**. If you choose **Clean up disk-space once threshold is reached**, enter a **Threshold of Disk-Used** in megabytes. For more information about the configuration options and how to configure a threshold, see [Configuring Docker Images Disk-Cleanup Scheduling](#).
9. Enter a number in the **Max Inflight Container Starts** textbox. This number configures the maximum number of started instances across the Diego cells in your deployment. For more information about this feature, see [Setting a Maximum Number of Started Containers](#).
10. Under **Enabling NFSv3 volume services**, select **Enable** or **Disable**. NFS volume services allow application developers to bind existing NFS volumes to their applications for shared file access. For more information, see the [Enabling NFS Volume Services](#) topic.

 **Note:** In a clean install, NFSv3 volume services is enabled by default. In an upgrade, NFSv3 volume services is set to the same setting as it was in the previous deployment.

11. (Optional) To configure LDAP for NFSv3 volume services, do the following:

Enabling NFSv3 volume services will allow application developers to bind existing NFS volumes to their applications for shared file access. *

☒ Enable

LDAP Service Account User

LDAP Service Account Password

LDAP Server Host

LDAP Server Port

LDAP User Fully-Qualified Domain Name

☐ Disable

Format of timestamps in Diego logs*

☒ RFC3339 timestamps (e.g. 2018-02-09T00:54:13.479724884Z)

☐ Seconds since the Unix epoch (e.g. 1518137653.479724884)

Save

- For **LDAP Service Account User**, enter the username of the service account in LDAP that will manage volume services.
- For **LDAP Service Account Password**, enter the password for the service account.
- For **LDAP Server Host**, enter the hostname or IP address of the LDAP server.
- For **LDAP Server Port**, enter the LDAP server port number. If you do not specify a port number, Ops Manager uses 389.
- For **LDAP User Fully-Qualified Domain Name**, enter the fully qualified path to the LDAP service account. For example, if you have a service account named `volume-services` that belongs to organizational units (OU) named `service-accounts` and `my-company`, and your domain is named `domain`, the fully qualified path looks like the following:

```
CN=volume-services,OU=service-accounts,OU=my-company,DC=domain,DC=com
```

12. By default, PAS manages container images using the [GrootFS](#) plugin for Garden-runC. If you experience issues with GrootFS, you can disable the plugin and use the image plugin built into Garden-runC.

13. Select the **Format of timestamps in Diego logs**, either **RFC3339 timestamps** or **Seconds since the Unix epoch**. Fresh PAS v2.2 installations default to **RFC3339 timestamps**, while upgrades to PAS v2.2 from previous versions default to **Seconds since the Unix epoch**.
14. You can optionally modify the **Default health check timeout**. The value configured for this field is the amount of time allowed to elapse between starting up an app and the first healthy response from the app. If the health check does not receive a healthy response within the configured timeout, then the app is declared unhealthy. The default timeout is seconds and the maximum configurable timeout is seconds.
15. Click **Save**.

Step 6: Configure Application Developer Controls

1. Select **Application Developer Controls**.

Configure restrictions and default settings for applications pushed to Application Service.

Maximum File Upload Size (MB) (min: 1024, max: 2048) *

Default App Memory (MB) (min: 64, max: 2048) *

Default App Memory Quota per Org (MB) (min: 10240, max: 102400) *

Maximum Disk Quota per App (MB) (min: 512, max: 20480) *

Default Disk Quota per App (MB) (min: 512, max: 20480) *

Default Service Instances Quota per Org (min: 0, max: 1000) *

Staging Timeout (Seconds) *

☐ Allow Space Developers to manage network policies

☒ Enable Service Discovery for Apps

Save

2. Enter the **Maximum File Upload Size (MB)**. This is the maximum size of an application upload.
3. Enter the **Default App Memory (MB)**. This is the amount of RAM allocated by default to a newly pushed application if no value is specified with the cf CLI.
4. Enter the **Default App Memory Quota per Org**. This is the default memory limit for all applications in an org. The specified limit only applies to the first installation of PAS. After the initial installation, operators can use the cf CLI to change the default value.

5. Enter the **Maximum Disk Quota per App (MB)**. This is the maximum amount of disk allowed per application.

Note: If you allow developers to push large applications, PAS may have trouble placing them on Cells. Additionally, in the event of a system upgrade or an outage that causes a rolling deploy, larger applications may not successfully re-deploy if there is insufficient disk capacity. Monitor your deployment to ensure your Cells have sufficient disk to run your applications.

6. Enter the **Default Disk Quota per App (MB)**. This is the amount of disk allocated by default to a newly pushed application if no value is specified with the cf CLI.
7. Enter the **Default Service Instances Quota per Org**. The specified limit only applies to the first installation of PAS. After the initial installation, operators can use the cf CLI to change the default value .
8. Enter the **Staging Timeout (Seconds)**. When you stage an application droplet with the Cloud Controller, the server times out after the number of seconds you specify in this field.
9. Select the **Allow Space Developers to manage network policies** checkbox to permit developers to manage their own network policies for their applications.
10. The **Enable Service Discovery for Apps** checkbox, which enables service discovery between applications, is enabled by default. To disable this feature, clear this checkbox. For more information about application service discovery, see the [App Service Discovery](#) section of the *Understanding Container-to-Container Networking* topic.
11. Click **Save**.

Step 7: Review Application Security Group

Setting appropriate [Application Security Groups](#) is critical for a secure deployment. Type ☐ in the box to acknowledge that once the Pivotal Application Service (PAS) deployment completes, you will review and set the appropriate application security groups. See [Restricting App Access to Internal PCF Components](#) for instructions.

Setting appropriate Application Security Groups that control application network policy is the responsibility of the Elastic Runtime administration team. Please refer to the Application Security Groups topic in the Pivotal Cloud Foundry documentation for more detail on completing this activity after the Elastic Runtime deployment completes.

Type X to acknowledge that you understand this message *

Save

Step 8: Configure UAA

1. Select **UAA**.
2. (Optional) Under **JWT Issuer URI**, enter the URI that UAA uses as the issuer when generating tokens.

JWT Issuer URI

3. Under **SAML Service Provider Credentials**, enter a certificate and private key to be used by UAA as a SAML Service Provider for signing outgoing SAML authentication requests. You can provide an existing certificate and private key from your trusted Certificate Authority or generate a self-signed certificate. The following domain must be associated with the certificate: `*.login.YOUR-SYSTEM-DOMAIN`.

Note: The Pivotal Single Sign-On Service and Pivotal Spring Cloud Services tiles require the `*.login.YOUR-SYSTEM-DOMAIN`.

- If the private key specified under **Service Provider Credentials** is password-protected, enter the password under **SAML Service Provider Key**

SAML Service Provider Credentials *

-----BEGIN CERTIFICATE-----
M
U
H
M
-----END CERTIFICATE-----

[Change](#)

SAML Service Provider Key Password

Secret

Password.

- (Optional) To override the default value, enter a custom SAML Entity ID in the **SAML Entity ID Override** field. By default, the SAML Entity ID is `http://login.YOUR-SYSTEM-DOMAIN` where `YOUR-SYSTEM-DOMAIN` is set in the **Domains > System Domain** field.
- For **Signature Algorithm**, choose an algorithm from the dropdown menu to use for signed requests and assertions. The default value is `SHA256`.
- (Optional) In the **Apps Manager Access Token Lifetime**, **Apps Manager Refresh Token Lifetime**, **Cloud Foundry CLI Access Token Lifetime**, and **Cloud Foundry CLI Refresh Token Lifetime** fields, change the lifetimes of tokens granted for Apps Manager and Cloud Foundry Command Line Interface (cf CLI) login access and refresh. Most deployments use the defaults.

Apps Manager Access Token Lifetime (in seconds) *

Apps Manager Refresh Token Lifetime (in seconds) *

Cloud Foundry CLI Access Token Lifetime (in seconds) *

Cloud Foundry CLI Refresh Token Lifetime (in seconds) *

Global Login Session Max Timeout (in seconds) *

Global Login Session Idle Timeout (in seconds) *

Customize Username Label (on login page) *

Customize Password Label (on login page) *

Proxy IPs Regular Expression *

8. (Optional) In the **Global Login Session Max Timeout** and **Global Login Session Idle Timeout** fields, change the maximum number of seconds before a global login times out. These fields apply to the following:
 - **Default zone sessions:** Sessions in Apps Manager, PCF Metrics, and other web UIs that use the UAA default zones
 - **Identity zone sessions:** Sessions in apps that use a UAA identity zone, such as a Single Sign-On service plan
9. (Optional) Customize the text prompts used for username and password from the cf CLI and Apps Manager login popup by entering values for **Customize Username Label (on login page)** and **Customize Password Label (on login page)**.
10. (Optional) The **Proxy IPs Regular Expression** field contains a pipe-delimited set of regular expressions that UAA considers to be reverse proxy IP addresses. UAA respects the `x-forwarded-for` and `x-forwarded-proto` headers coming from IP addresses that match these regular expressions. To configure UAA to respond properly to Gorouter or HAProxy requests coming from a public IP address, append a regular expression or regular expressions to match the public IP address.
11. You can configure UAA to use an internal MySQL database provided with PCF, or you can configure an external database provider. Follow the procedures in either the [Internal Database Configuration](#) or the [External Database Configuration](#) section below.

 **Note:** If you are performing an upgrade, do not modify your existing internal database configuration or you may lose data. You must migrate your existing data before changing the configuration. See [Upgrading Pivotal Cloud Foundry](#) for additional upgrade information, and contact [Pivotal Support](#) for help.

Internal Database Configuration

When you configure the UAA to use an internal MySQL database, it uses the type of database selected in the **Databases** pane. See the [Configure Internal Databases](#) section for details.

1. Select **Internal MySQL**.

Choose the location of your UAA database *

☒ Internal MySQL (preferred for complete high-availability)

☐ External (preferred if, for example, you use AWS RDS)

 **Note:** If you configure your system databases as external in the **Databases** pane, selecting Internal MySQL in the **UAA** pane has no effect.

2. Click **Save**.
3. Ensure that you complete the [Configure Internal MySQL](#) step later in this topic to configure high availability for your internal MySQL databases.

External Database Configuration

1. From the **UAA** section in Pivotal Application Service (PAS), select **External**.

Choose the location of your UAA database *

☐ Internal MySQL (preferred for complete high-availability)

☒ External (preferred if, for example, you use AWS RDS)

Hostname *

TCP Port *

Username *

Password *

2. For **Hostname**, enter the hostname of the database server.
3. For **TCP Port**, enter the port of the database server.
4. For **User Account and Authentication database username**, specify a unique username that can access this specific database on the database server.
5. For **User Account and Authentication database password**, specify a password for the provided username.
6. Click **Save**.

Step 9: Configure CredHub

 **Note:** Enabling CredHub is not required. However, you cannot leave the fields under **Encryption Keys** blank. If you do not intend to use CredHub, enter any text in the **Name** and **Key** fields as placeholder values.

1. Select **CredHub**.
2. Choose the location of your CredHub database. PAS includes this CredHub database for services to store their service instance credentials.

 **Note:** You cannot choose **Internal** for the CredHub database if you choose **External** for your System Databases. See [Configure System](#)

Databases below.

Configure the CredHub Server

Choose the location of your CredHub database *

- ☒ Internal MySQL (preferred for complete high-availability)
- ☐ External (preferred if, for example, you use Google Cloud SQL)

If you chose **External**, enter the following:

- **Hostname.** This is the IP address of your database server.
- **TCP Port.** This is the port of your database server, such as `3306`.
- **Username.** This is a unique username that can access your CredHub database on the database server.
- **Password.** This is the password for the provided username.
- **Database CA Certificate.** This certificate is used when encrypting traffic to and from the database.

3. Under **Encryption Keys**, specify one or more keys to use for encrypting and decrypting the values stored in the CredHub database.

Encryption Keys

Name *

Name of the encryption key.

Provider*

Key *

☐ Primary

- **Name.** This is the name of the encryption key.
 - If you plan to use internal encryption, enter any key name.
 - If you plan to use an HSM as your encryption provider, enter a key name that already exists on your HSM or a new key name. For each new key name, CredHub generates a key in **HSM Provider Partition** that you configure below.
- **Provider.** This is the provider of the encryption key. If you plan to configure an HSM provider and HSM servers below, select **HSM**. Otherwise, select **Internal**.
- **Key.** If you select internal encryption, this key is used for encrypting all data. The key must be at least 20 characters long.
 - If you selected **Internal** above, enter a randomly generated value under **Key**.
 - If you selected **HSM** above, enter a placeholder value under **Key**. CredHub does not use this key for encryption. However, you cannot leave the **Key** field blank.
- **Primary.** This checkbox is used for marking the key you specified above as the primary encryption key. You must mark one key as **Primary**. Do not mark more than one key as **Primary**.

Note: For information about using additional keys for key rotation, see the [Rotating Runtime CredHub Encryption Keys](#) topic.

4. (Optional) To configure CredHub to use an HSM, complete the following fields:

- **HSM Provider Partition.** This is the name of the HSM provider partition.
- **HSM Provider Partition Password.** This password is used to access the HSM provider partition.
- **HSM Provider Client Certificate.** This is the client certificate for the HSM. For more information, see [Create and Register HSM Clients](#) in the

Preparing CredHub HSMs for Configuration topic.

- In the **HSM Provider Servers** section, click **Add** to add an HSM server. You can add multiple HSM servers. For each HSM server, complete the following fields:
 - **Host Address.** This is the host name or IP address of the HSM server.
 - **Port.** This is the port of the HSM server. If you do not know your port address, enter `1792`.
 - **Partition Serial Number.** This is the serial number of the HSM partition.
 - **HSM Certificate.** This is the certificate for the HSM server. The HSM presents this certificate to CredHub to establish a two-way TLS connection.

5. If your deployment uses any PCF services that support storing service instance credentials in CredHub and you want to enable this feature, select the **Secure Service Instance Credentials** checkbox.

6. Click **Save**.

7. Select the **Resource Config** pane.

8. Under the **Job** column of the **CredHub** row, set the number of instances to `2`. This is the minimum instance count required for high availability.

9. Click **Save**.

For more information about using CredHub for securing service instance credentials, see [Securing Service Instance Credentials with Runtime CredHub](#).

Step 10: Configure Authentication and Enterprise SSO

1. Select **Authentication and Enterprise SSO**.

Configure your user store access, which can be an internal user store (managed by Cloud Foundry's UAA) or an external user store (LDAP or SAML). You can also adjust the lifetimes of authentication tokens.

Configure your UAA user account store with either internal or external authentication mechanisms *

☒ Internal UAA (provided by Elastic Runtime; configure your password policy below)

Minimum Password Length *

Minimum Uppercase Characters Required for Password *

Minimum Lowercase Characters Required for Password *

Minimum Numerical Digits Required for Password *

Minimum Special Characters Required for Password *

Maximum Password Entry Attempts Allowed *

2. To authenticate user sign-ons, your deployment can use one of three types of user database: the UAA server's internal user store, an external SAML identity provider, or an external LDAP server.

- To use the internal UAA, select the **Internal** option and follow the instructions in the [Configuring UAA Password Policy](#) topic to configure your password policy.
- To connect to an external identity provider through SAML, scroll down to select the **SAML Identity Provider** option and follow the instructions in the [Configuring PCF for SAML](#) section of the *Configuring Authentication and Enterprise SSO for Pivotal Application Service (PAS)* topic.
- To connect to an external LDAP server, scroll down to select the **LDAP Server** option and follow the instructions in the [Configuring LDAP](#) section of the *Configuring Authentication and Enterprise SSO for PAS* topic.

3. Click **Save**.

Step 11: Configure System Databases

You can configure PAS to use an internal MySQL database provided with PCF, or you can configure an external database provider for the databases required by PAS.

 **Note:** If you are performing an upgrade, do not modify your existing internal database configuration or you may lose data. You must migrate your existing data first before changing the configuration. Contact Pivotal Support for help. See [Upgrading Pivotal Cloud Foundry](#) for additional upgrade information.

Internal Database Configuration

If you want to use internal databases for your deployment, perform the following steps:

1. Select **Databases**.

2. Select one of the **Internal Databases** options:

- **Internal Databases - MySQL - Percona XtraDB Cluster** uses [Percona Server](#) with TLS encryption between server cluster nodes.
- **Internal Databases - MySQL - MariaDB Galera Cluster** uses [MariaDB](#) with cluster nodes communicating over plaintext.

⚠ warning: Changing existing internal databases from **MySQL - MariaDB Galera Cluster** to **MySQL - Percona XtraDB Cluster** migrates the databases after you click **Apply Changes**, causing temporary system downtime. See [Migrate to Internal Percona MySQL](#) for details.

Choose the location of your system databases. Please consult the documentation for migrating existing installations from MariaDB to Percona. *

- ☒ Internal Databases - MySQL - Percona XtraDB Cluster
- ☐ Internal Databases - MySQL - MariaDB Galera Cluster (deprecated - planned to be removed in PAS 2.4)
- ☐ External Databases - (e.g. AWS RDS)

Save

3. Click **Save**.

Then proceed to [Step 12: \(Optional\) Configure Internal MySQL](#) to configure high availability for your internal MySQL databases.

External Database Configuration

⚠ warning: Protect whichever database you use in your deployment with a password.

To create your Pivotal Application Service (PAS) databases, follow the procedure below.

💡 Note: Exact configurations depend on your database provider. The following procedure uses AWS RDS as an example.

1. Add the `ubuntu` account key pair from your IaaS deployment to your local SSH profile so you can access the Ops Manager VM. For example, in AWS, you add a key pair created in AWS:

```
$ ssh-add aws-keypair.pem
```

2. SSH in to your Ops Manager using the Ops Manager FQDN and the username `ubuntu`:

```
$ ssh ubuntu@OPS-MANAGER-FQDN
```

3. Log in to your MySQL database instance using the appropriate hostname and user login values configured in your IaaS account. For example, to log in to your AWS RDS instance, run the following MySQL command:

```
$ mysql --host=RDSHOSTNAME --user=RDSUSERNAME --password=RDSPASSWORD
```

4. Run the following MySQL commands to create databases for the PAS components that require a relational database:

```
CREATE database ccd;
CREATE database notifications;
CREATE database autoscale;
CREATE database app_usage_service;
CREATE database routing;
CREATE database diego;
CREATE database account;
CREATE database nfsvolume;
CREATE database networkpolicyserver;
CREATE database silk;
CREATE database locket;
CREATE database uaa;
CREATE database credhub;
```

💡 Note: The command `CREATE database credhub;` is optional if you have no CredHub instances. By default, CredHub has `0` instances.

5. Type `exit` to quit the MySQL client, and `exit` again to close your connection to the Ops Manager VM.
6. In PAS, select **Databases**.
7. Select the **External Databases** option.

 **Note:** If you configure databases as external, you cannot configure an internal database in the **UAA** pane.

8. For **Hostname**, enter the hostname of the database server.
9. For **TCP Port**, enter the port of the database server.
10. Each component that requires a relational database has two corresponding fields: one for the database username and one for the database password. For each set of fields, specify a unique username that can access this specific database on the database server and a password for the provided username.

 **Note:** Ensure that the networkpolicyserver database user has the `ALL PRIVILEGES` permission.

11. Click **Save**.

Step 12: (Optional) Configure Internal MySQL

 **Note:** You only need to configure this section if you have selected one of the **Internal Databases - MySQL** options in the **Databases** section.

To use internal MySQL in High Availability configuration, you define a load balancer rule that lets PAS components send queries a single hostname backed by two redundant proxies. Each proxy then directs query traffic to three MySQL server nodes.

1. Allocate an internal load balancer rule to balance traffic between two static IP addresses. The static IP addresses cannot be within the range that that you have reserved for PAS.
The load balancer rule is separate from the software provided by Pivotal, and you need to define it within your infrastructure.
 - **Make your idle time out long enough to not interrupt long-running queries.** When queries take a long time, the load balancer can time out and interrupt the query.
For example, [AWS's Elastic Load Balancer](#) has a default idle timeout of 60 seconds, so queries that take longer than this duration sever the MySQL connection and return an error.
 - **Configure a healthcheck or monitor, using TCP against port 1936.** This defaults to TCP port `1936`, to maintain backwards compatibility with previous releases. This port is not configurable. Unauthenticated healthchecks against port 3306 may cause the service to become unavailable and require manual intervention to fix.
 - **Configure the load balancer to route traffic for TCP port 3306 to the IPs of all proxy instances on TCP port 3306.**
 - Record the hostname of the load balancer rule and the two static IP addresses.

 **warning:** You must configure a load balancer to achieve complete high availability.

2. From the PAS tile in Ops Manager, Select **Internal MySQL**.
3. In the **MySQL Proxy IPs** field, enter the static IP addresses used by the internal MySQL load balancer rule.

Only configure this section if you selected Internal Databases - MySQL in the previous Databases section.

A proxy tier routes MySQL connections from internal components to healthy cluster nodes. Configure DNS and/or your own load balancer to point to multiple proxy instances for increased availability. TCP healthchecks can be configured against port 1936.

The automated backups functionality works with any S3-compatible file store that can receive your backup files.

MySQL Proxy IPs

MySQL Service Hostname

4. For **MySQL Service Hostname**, enter the IP address or hostname for your load balancer. If you leave this field blank, components are configured with the IP address of the first proxy instance entered above.
5. In the **Replication canary time period** field, leave the default of 30 seconds or modify the value based on the needs of your deployment. Lower numbers cause the canary to run more frequently, which means that the canary reacts more quickly to replication failure but adds load to the database.
6. In the **Replication canary read delay** field, leave the default of 20 seconds or modify the value based on the needs of your deployment. This field configures how long the canary waits, in seconds, before verifying that data is replicating across each MySQL node. Clusters under heavy load can experience a small replication lag as write-sets are committed across the nodes.
7. (**Required**): In the **E-mail address** field, enter the email address where the MySQL service sends alerts when the cluster experiences a replication issue or when a node is not allowed to auto-rejoin the cluster.
8. To prohibit the creation of command line history files on the MySQL nodes, disable the **Allow Command History** checkbox.
9. To allow the admin and roadmin to connect from any remote host, enable the **Allow Remote Admin Access** checkbox. When the checkbox is disabled, admins must `bosh ssh` into each MySQL VM to connect as the MySQL super user.

 **Note:** Network configuration and Application Security Groups restrictions may still limit a client's ability to establish a connection with the databases.

10. For **Cluster Probe Timeout**, enter the maximum amount of time, in seconds, that a new node will search for existing cluster nodes. If left blank, the default value is 10 seconds.

Replication canary time period *

30

Replication canary read delay *

20

E-mail address (required) *

Fill in your desired email address

☒ Allow Command History

Cluster Probe Timeout

11. For **Max Connections**, enter the maximum number of connections allowed to the database. If left blank, the default value is 1500.
12. If you want to log audit events for internal MySQL, select **Enable server activity logging** under **Server Activity Logging**.
 - a. For the **Event types** field, you can enter the events you want the MySQL service to log. By default, this field includes `connect` and `query`, which tracks who connects to the system and what queries are processed.

13. Enter values for the following fields:
 - **Load Balancer Healthy Threshold:** Specifies the amount of time, in seconds, to wait until declaring the MySQL Proxy instance started. This allows an external load balancer time to register the instance as healthy.
 - **Load Balancer Unhealthy Threshold:** Specifies the amount of time, in seconds, that the MySQL Proxy continues to accept connections before shutting down. During this period, the Healthcheck reports as unhealthy to cause load balancers to fail over to other proxies. You must enter a value greater than or equal to the maximum time it takes your load balancer to consider a proxy instance unhealthy, given repeated failed healthchecks.
14. If you want to enable the MySQL interruptor feature, select the checkbox to **Prevent node auto re-join**. This feature stops all writes to the MySQL database if it notices an inconsistency in the dataset between the nodes. For more information, see the [Interruptor](#) section in the MySQL for PCF documentation.
15. Click **Save**.

For more information on how to monitor the node health of your MySQL Proxy instances, see [Using the MySQL Proxy](#).

Step 13: Configure File Storage

To minimize system downtime, Pivotal recommends using highly resilient and redundant *external* filestores for your Pivotal Application Service (PAS) file storage.

When configuring file storage for the Cloud Controller in PAS, you can select one of the following:

- Internal WebDAV filestore
- External S3-compatible or Ceph-compatible filestore
- External Google Cloud Storage with Access Key and Secret Key
- External Google Cloud Storage with Service Account
- External Azure Cloud Storage

For production-level PCF deployments on Azure, the recommended selection is Azure Storage. For more information about production-level PCF deployments on Azure, see the [Reference Architecture for Pivotal Cloud Foundry on Azure](#).

For more factors to consider when selecting file storage, see [Considerations for Selecting File Storage in Pivotal Cloud Foundry](#).

Internal Filestore

Internal file storage is only appropriate for small, non-production deployments.

To use the PCF internal filestore, perform the following steps:

1. In the Pivotal Application Service (PAS) tile, select **File Storage**.
2. Select **Internal WebDAV**, and click **Save**.

External Azure Storage

To use external Azure file storage for your Pivotal Application Service (PAS) filestore, perform the following steps:

1. Select the **External AzureStorage** option.

Configure your Cloud Controller's filesystem*

☐ Internal WebDAV (provided by Elastic Runtime)
 ☐ External S3-Compatible File Store (if you want to use a service like S3 or Ceph)
 ☐ External Google Cloud Storage
 ☒ External Azure Storage

Account Name *

pcfstorageaccount

Access Key *

.....

Buildpacks Container Name *

pcfbuildpacks

Droplets Container Name *

pcfdroplets

Packages Container Name *

pcfpackages

Resources Container Name *

pcfresources

2. To create a new storage account and storage containers for the PAS filestore, perform the following steps.
 - In the Azure Portal, navigate to the **Storage accounts** tab.
 - Click on the plus icon to add a new storage account.
 - In the **Name** field, enter a unique name (all lowercase, 3 to 24 alphanumeric characters) for the storage account.
 - For the **Deployment model**, select **Resource manager**.
 - For **Account kind**, select **General purpose**.

- For **Performance**, select **Standard**.
 - From the **Replication** dropdown, select **Locally-redundant storage (LRS)**.
 - For **Storage service encryption**, select **Disabled**.
 - From the **Subscription** dropdown, select the subscription where you want to deploy PCF resources.
 - For **Resource group**, select **Use existing** and enter the name of the resource group where you deployed PAS.
 - From **Location** the dropdown, select the **Location** where you are deploying PCF.
 - Click **Create**.
 - After the storage account is created, select the new storage account from the dashboard.
 - Navigate to the **Blob Service** section of the storage account, and then click on **Containers** to create one or more containers in this storage account for buildpacks, droplets, resources, and packages.
 - For each container that you create, set the **Access type** to **Private**.
3. In PAS, enter the name of the storage account you created for **Account Name**.
 4. In the **Secret Key** field, enter one of the access keys provided for the storage account. To obtain a value for this fields, visit the Azure Portal, navigate to the **Storage accounts** tab and click on **Access keys**.
 5. For the **Buildpacks Container Name**, enter the container name for storing your app buildpacks.
 6. For **Droplets Container Name**, enter the container name for your app droplet storage. Pivotal recommends that you use a unique container name, but you can use the same container name as the previous step.
 7. For **Resources Container Name**, enter the container name for resources. Pivotal recommends that you use a unique container name, but you can use the same container name as the previous step.
 8. For **Packages Container Name**, enter the container name for packages. Pivotal recommends that you use a unique container name, but you can use the same container name as the previous step.
 9. Click **Save**.

 **Note:** To enable backup and restore of your PAS tile that uses S3 compatible blobstore, see [Enable External Blobstore Backups](#).

Other IaaS Storage Options

[Google Cloud Storage](#) and [External S3-Compatible File Storage](#) are also available as file storage options but are not recommended for typical PCF on Azure installations.

Step 14: (Optional) Configure System Logging

You can configure system logging in PAS to forward log messages from PAS component VMs to an external service. Pivotal recommends forwarding logs to an external service for use in troubleshooting.

 **Note:** The following instructions explain how to configure system logging for PAS component VMs. To forward logs from PCF tiles to an external service, you must also configure system logging in each tile. See the documentation for the given tiles for information about configuring system logging.

To configure system logging in PAS, do the following:

1. In the PAS **Settings** tab, select the **System Logging** pane. The following image shows the **System Logging** pane.

Optionally configure rsyslog to forward platform component logs to an external service. If you do not fill these fields, platform logs will not be forwarded but will remain available on the component VMs and for download via Ops Manager.

Address

Port

Transport Protocol

Encrypt syslog using TLS?*

- ☒ No
☐ Yes

Syslog Drain Buffer Size (# of messages) *

☒ Include container metrics in SysLog Drains

☒ Enable Cloud Controller security event logging

☐ Use TCP for file forwarding local transport

☒ Don't Forward Debug Logs

Custom rsyslog Configuration

Save

2. For **Address**, enter the IP address of the syslog server.
3. For **Port**, enter the port of the syslog server. The default port for a syslog server is `514`.

 **Note:** The host must be reachable from the PAS network and accept UDP or TCP connections. Ensure the syslog server listens on external interfaces.

4. For **Transport Protocol**, select a transport protocol for log forwarding.
5. For **Encrypt syslog using TLS?**, select **Yes** to use TLS encryption when forwarding logs to a remote server.
 - a. For **Permitted Peer**, enter either the name or SHA1 fingerprint of the remote peer.
 - b. For **TLS CA Certificate**, enter the TLS CA certificate for the remote server.
6. For **Syslog Drain Buffer Size**, enter the number of messages from the Loggregator Agent that the Doppler server can store before it begins to drop messages. See the [Loggregator Guide for Cloud Foundry Operators](#) topic for more details.
7. Disable the **Include container metrics in Syslog Drains** checkbox to prevent the [CF Drain CLI plugin](#) from including app container metrics in syslog drains. This feature is enabled by default.

8. Enable the **Enable Cloud Controller security event logging** checkbox to include security events in the log stream. This feature logs all API requests, including the endpoint, user, source IP address, and request result, in the Common Event Format (CEF).
9. Enable the **Use TCP for file forwarding local transport** checkbox to transmit logs over TCP. This prevents log truncation, but may cause performance issues.
10. Disable the **Don't Forward Debug Logs** checkbox to forward DEBUG syslog messages to an external service. This checkbox is enabled by default.

Note: Some PAS components generate a high volume of DEBUG syslog messages. Enabling the **Don't Forward Debug Logs** checkbox prevents PAS components from forwarding the DEBUG syslog messages to external services. However, PAS still writes the messages to the local disk.

11. For **Custom rsyslog Configuration**, enter a custom syslog rule. For more information about adding custom syslog rules, see [Customizing Syslog Rules](#).
12. Click **Save**.

To configure Ops Manager for system logging, see the [Settings](#) section in the *Using the Ops Manager Interface* topic.

Step 15: (Optional) Customize Apps Manager

This section describes how to configure **Custom Branding** and **Apps Manager** to customize the appearance and functionality of Apps Manager. For more information about the **Custom Branding** configuration settings, see [Custom Branding Apps Manager](#).

1. Select **Custom Branding**. Use this section to configure the text, colors, and images of the interface that developers see when they log in, create an account, reset their password, or use Apps Manager.

Customize colors, images, and text for Apps Manager and the Cloud Foundry login portal.

Company Name

- ▶ Tools 🗑️

Apps Manager Memory Usage (MB) (min: 128)

Invitations Memory Usage (MB) (min: 256)

Apps Manager Polling Interval *

30

Apps manager polling interval in seconds. As a workaround to reduce load on the Cloud Controller API, increase the polling interval or set to 0 to stop polling. Values between 0 and 30 will default to 30 seconds.

Save

4. Select **Enable Invitations** to enable invitations in Apps Manager. Space Managers can invite new users for a given space, Org Managers can invite new users for a given org, and Admins can invite new users across all orgs and spaces. See the [Inviting New Users](#) section of the *Managing User Roles with Apps Manager* topic for more information.
5. Select **Display Marketplace Service Plan Prices** to display the prices for your services plans in the Marketplace.
6. Enter the **Supported currencies as JSON** to appear in the Marketplace. Use the format `{ "CURRENCY-CODE": "SYMBOL" }`. This defaults to `{ "usd": "$", "eur": "€" }`.
7. Use **Product Name**, **Marketplace Name**, and **Customize Sidebar Links** to configure page names and sidebar links in the **Apps Manager** and **Marketplace** pages.
8. The **Apps Manager Memory Usage (MB)** field sets the memory limit with which to deploy the Apps Manager app. Use this field to increase the memory limit if the app fails to start with an `out of memory` error.
9. The **Invitations Memory Usage (MB)** field sets the memory limit with which to deploy the Invitations app. Use this field to increase the memory limit if the app fails to start with an `out of memory` error.

10. The **Apps Manager Polling Interval** field provides a temporary fix if Apps Manager usage degrades Cloud Controller response times. In this case, you can use this field to reduce the load on the Cloud Controller and ensure Apps Manager remains available while you troubleshoot the Cloud Controller. Pivotal recommends that you do not keep this field modified as a long term fix because it can degrade Apps Manager performance. You can optionally do the following:

- Increase the polling interval above the default of `30` seconds.

 **Note:** If you enter a value between `0` and `30`, the field is automatically set to `30`.

- Disable polling by entering `0`. This stops Apps Manager from refreshing data automatically, but users can update displayed data by reloading Apps Manager manually.

11. Click **Save** to save your settings in this section.

Step 16: (Optional) Configure Email Notifications

PAS uses SMTP to send invitations and confirmations to Apps Manager users. You must complete the **Email Notifications** page if you want to enable end-user self-registration.

1. Select **Email Notifications**.

Configure Simple Mail Transfer Protocol for the Notifications application to send email notifications about your deployment. This application is deployed as an errand in Elastic Runtime. If you do not need this service, leave this section blank and disable the Notifications and Notifications UI errands.

From Email

Address of SMTP Server

Port of SMTP Server

SMTP Server Credentials

[Change](#)

☒ SMTP Enable Automatic STARTTLS

SMTP Authentication Mechanism*

SMTP CRAMMD5 secret

Save

2. Enter your reply-to and SMTP email information.

 **Note:** For GCP, you must use port `2525`. Ports `25` and `587` are not allowed on GCP Compute Engine.

3. Verify your authentication requirements with your email administrator and use the **SMTP Authentication Mechanism** dropdown to select `None`, `Plain`, or `CRAMMD5`. If you have no SMTP authentication requirements, select `None`.

- If you selected `CRAMMD5` as your authentication mechanism, enter a secret in the **SMTP CRAMMD5 secret** field.
- Click **Save**.

Note: If you do not configure the SMTP settings using this form, the administrator must create orgs and users using the cf CLI. See [Creating and Managing Users with the cf CLI](#) for more information.

Step 17: (Optional) Configure App Autoscaler

To use App Autoscaler, you must create an instance of the service and bind it to an app. To create an instance of App Autoscaler and bind it to an app, see [Set Up App Autoscaler](#) in the *Scaling an Application Using App Autoscaler* topic.

- Click **App Autoscaler**.

Configure the App Autoscaler

Autoscaler Instance Count (min: 1) *

Autoscaler API Instance Count (min: 1) *

Metric Collection Interval (min: 60, max: 3600) (min: 60, max: 3600) *

Scaling Interval (min: 15, max: 120) (min: 15, max: 120) *

☐ Verbose Logging

☐ Disable API Connection Pooling

☒ Enable Notifications

Save

- Review the following settings:

- Autoscaler Instance Count:** How many instances of the App Autoscaler service you want to deploy. The default value is `3`. For high availability, set this number to `3` or higher. You should set the instance count to an odd number to avoid split-brain scenarios during leadership elections. Larger environments may require more instances than the default number.
- Autoscaler API Instance Count:** How many instances of the App Autoscaler API you want to deploy. The default value is `1`. Larger environments may require more instances than the default number.
- Metric Collection Interval:** How many seconds of data collection you want App Autoscaler to evaluate when making scaling decisions. The minimum interval is 60 seconds, and the maximum interval is 3600 seconds. The default value is `120`. Increase this number if the metrics you use in your scaling rules are emitted less frequently than the existing Metric Collection Interval.
- Scaling Interval:** How frequently App Autoscaler evaluates an app for scaling. The minimum interval is 15 seconds, and the maximum interval is 120 seconds. The default value is `35`.
- Verbose Logging** (checkbox): Enables verbose logging for App Autoscaler. Verbose logging is disabled by default. Select this checkbox to see more detailed logs. Verbose logs show specific reasons why App Autoscaler scaled the app, including information about minimum and maximum instance limits, App Autoscaler's status. For more information about App Autoscaler logs, see [App Autoscaler Events and Notifications](#).
- Disable API Connection Pooling:** API connection pooling increases performance by reducing the cost associated with establishing new connections. If you do not want to keep connections open for reuse, select this option.

3. Click **Save**.

Step 18: Configure Cloud Controller

1. Click **Cloud Controller**.

Configure the Cloud Controller

Cloud Controller DB Encryption Key

Secret

Enabling CF API Rate Limiting will prevent API consumers from overwhelming the platform API servers. Limits are imposed on a per-user or per-client basis and reset on an hourly interval. *

☐ Enable
 ☒ Disable

Save

2. Enter your **Cloud Controller DB Encryption Key** if all of the following are true:

- You deployed Pivotal Application Service (PAS) previously.
- You then stopped PAS or it crashed.
- You are re-deploying PAS with a backup of your Cloud Controller database.

See [Backing Up Pivotal Cloud Foundry](#) for more information.

3. CF API Rate Limiting prevents API consumers from overwhelming the platform API servers. Limits are imposed on a per-user or per-client basis and reset on an hourly interval.

To disable CF API Rate Limiting, select **Disable** under **Enable CF API Rate Limiting**. To enable CF API Rate Limiting, perform the following steps:

- Under **Enable CF API Rate Limiting**, select **Enable**.
- For **General Limit**, enter the number of requests a user or client is allowed to make over an hour interval for all endpoints that do not have a custom limit. The default value is `2000`.
- For **Unauthenticated Limit**, enter the number of requests an unauthenticated client is allowed to make over an hour interval. The default value is `100`.

4. Click **Save**.

Step 19: Configure Smoke Tests

The Smoke Tests errand runs basic functionality tests against your Pivotal Application Service (PAS) deployment after an installation or update. In this section, choose where to run smoke tests. In the **Errands** section, you can choose whether or not to run the Smoke Tests errand.

1. Select **Smoke Tests**.
2. If you have a shared apps domain, select **Temporary space within the system organization**, which creates a temporary space within the `system` organization for running smoke tests and deletes the space afterwards. Otherwise, select **Specified org and space** and complete the fields to specify where you want to run smoke tests.

Specify a Cloud Foundry organization and space where smoke tests can run if in the future you delete your Elastic Runtime deployment domains.

Choose where to deploy applications when running the smoke tests *

- ☐ Temporary space within the system organization (This is deleted after smoke tests finish.)
- ☒ Specified org and space (The org and space must have a domain available for routing.)

Organization *

Space *

Domain *

Save

3. Click **Save**.

Step 20: (Optional) Enable Advanced Features

The **Advanced Features** section of Pivotal Application Service (PAS) includes new functionality that may have certain constraints. Although these features are fully supported, Pivotal recommends caution when using them in production environments.

Diego Cell Memory and Disk Overcommit

If your apps do not use the full allocation of disk space and memory set in the **Resource Config** tab, you might want use this feature. These fields control the amount to overcommit disk and memory resources to each Diego Cell VM.

For example, you might want to use the overcommit if your apps use a small amount of disk and memory capacity compared to the amounts set in the **Resource Config** settings for **Diego Cell**.

Note: Due to the risk of app failure and the deployment-specific nature of disk and memory use, Pivotal has no recommendation about how much, if any, memory or disk space to overcommit.

To enable overcommit, do the following:

1. Select **Advanced Features**.

Cell Memory Capacity (MB) (min: 1)

Cell Disk Capacity (MB) (min: 1)

2. Enter the total desired amount of Diego cell memory value in the **Cell Memory Capacity (MB)** field. Refer to the **Diego Cell** row in the **Resource Config** tab for the current Cell memory capacity settings that this field overrides.
3. Enter the total desired amount of Diego cell disk capacity value in the **Cell Disk Capacity (MB)** field. Refer to the **Diego Cell** row in the **Resource Config** tab for the current Cell disk capacity settings that this field overrides.
4. Click **Save**.

 **Note:** Entries made to each of these two fields set the total amount of resources allocated, not the overage.

Whitelist for Non-RFC-1918 Private Networks

Some private networks require extra configuration so that internal file storage (WebDAV) can communicate with other PCF processes.

The **Whitelist for non-RFC-1918 Private Networks** field is provided for deployments that use a non-RFC 1918 private network. This is typically a private network other than `10.0.0.0/8`, `172.16.0.0/12`, or `192.168.0.0/16`.

Most PCF deployments do not require any modifications to this field.

To add your private network to the whitelist, do the following:

1. Select **Advanced Features**.
2. Append a new `allow` rule to the existing contents of the **Whitelist for non-RFC-1918 Private Networks** field.

Whitelist for non-RFC-1918 Private Networks *

allow 10.0.0.0/8;;allow 172.16.0.0/12;;allow .

If your Elastic Runtime deployment is using a private network that is not RFC 1918 (10.0.0.0/8, 172.16.0.0/12, 192.168.0.0/16), then you must type in "allow <your-network>;" here. It is important to include the word "allow" and the semi-colon at the end. For example, "allow 172.99.0.0/24;"

Include the word `allow`, the network CIDR range to allow, and a semi-colon (`;`) at the end. For example: `allow 172.99.0.0/24;`

3. Click **Save**.

CF CLI Connection Timeout

The **CF CLI Connection Timeout** field allows you to override the default five second timeout of the Cloud Foundry Command Line Interface (cf CLI) used within your PCF deployment. This timeout affects the cf CLI command used to push PAS errand apps such as Notifications, Autoscaler, and Apps Manager.

Set the value of this field to a higher value, in seconds, if you are experiencing domain name resolution timeouts when pushing errands in PAS.

To modify the value of the **CF CLI Connection Timeout**, perform the following steps:

1. Select **Advanced Features**.

CF CLI Connection Timeout

15

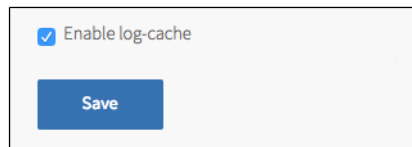

2. Add a value, in seconds, to the **CF CLI Connection Timeout** field.
3. Click **Save**.

Log Cache

Log Cache is an in-memory caching layer for logs and metrics. This Loggregator feature lets users filter and query logs through a CLI or API endpoints. Cached logs are available on demand. For more information about Log Cache, see [Enable Log Cache](#) in the *Configuring Logging in PASTopic*.

To configure the **Enable log-cache** checkbox, do the following:

1. Select **Advanced Features**.

2. Select or deselect the **Enable log-cache** checkbox.
3. Click **Save**.

Database Connection Limits

You can configure the maximum number of concurrent database connections that diego and container networking components can have. Use the field beginning with **Maximum number of open connections...** for a given component. The placeholder values for each field are the default values.

When there are not enough connections available, such as during a time of heavy load, components may experience degraded performance and sometimes failure. To resolve or prevent this, you can increase and fine-tune database connection limits for the component.

⚠ warning: Decreasing the value of this field for a component may affect the amount of time it takes for it to respond to requests.

Step 21: Configure Errands

Errands are scripts that Ops Manager runs automatically when it installs or uninstalls a product, such as a new version of Pivotal Application Service (PAS). There are two types of errands: *post-deploy errands* run after the product is installed, and *pre-delete errands* run before the product is uninstalled.

By default, Ops Manager always runs all errands.

The PAS tile **Errands** pane lets you change these run rules. For each errand, you can select **On** to run it always or **Off** to never run it.

For more information about how Ops Manager manages errands, see the [Managing Errands in Ops Manager](#) topic.

💡 Note: Several errands, such as App Autoscaler and Notifications, deploy apps that provide services for your deployment. When one of these apps is running, selecting **Off** for the corresponding errand on a subsequent installation does not stop the app.

- **Smoke Test Errand** verifies that your deployment can do the following:
 - Push, scale, and delete apps
 - Create and delete orgs and spaces
- **Usage Service Errand** deploys the Pivotal Usage Service application, which Apps Manager depends on.
- **Apps Manager Errand** deploys Apps Manager, a dashboard for managing apps, services, orgs, users, and spaces. Until you deploy Apps Manager, you must perform these functions through the cf CLI. After Apps Manager has been deployed, Pivotal recommends setting this errand to **Off** for subsequent PAS deployments. For more information about Apps Manager, see the [Getting Started with the Apps Manager](#) topic.
- **Notifications Errand** deploys an API for sending email notifications to your PCF platform users.

💡 Note: The Notifications app requires that you [configure SMTP](#) with a username and password, even if you set the value of **SMTP Authentication Mechanism** to `none`.

- **Notifications UI Errand** deploys a dashboard for users to manage notification subscriptions.
- **App Autoscaler Errand** enables you to configure your apps to automatically scale in response to changes in their usage load. See the [Scaling an Application Using Autoscaler](#) topic for more information.
- **NFS Broker Errand** enables you to use NFS Volume Services by installing the NFS Broker app in PAS. See the [Enabling NFS Volume Services](#) topic for more information.

Step 22: Configure Resources

1. Select **Resource Config**.

| Resource Config | | | | |
|---------------------|--------------|----------------------|---|---------------|
| JOB | INSTANCES | PERSISTENT DISK TYPE | VM TYPE | LOAD BALANCER |
| Consul | Automatic: 3 | Automatic: 1 GB | Automatic: Standard_F1s (cpu: 1, ram: 2 GB, disk: 1 | |
| NATS | Automatic: | None | Automatic: Standard_F1s (cpu: 1, ram: 2 GB, disk: 1 | |
| etcd | Automatic: 3 | Automatic: 1 GB | Automatic: Standard_F1s (cpu: 1, ram: 2 GB, disk: 1 | |
| File Storage | Automatic: 1 | Automatic: 100 GB | Automatic: Standard_F2s (cpu: 2, ram: 4 GB, disk: 3 | |
| MySQL Proxy | Automatic: | None | Automatic: Standard_F1s (cpu: 1, ram: 2 GB, disk: 1 | |
| MySQL Server | Automatic: 3 | Automatic: 100 GB | Automatic: Standard_DS11_v2 (cpu: 2, ram: 14 GB, | |
| Backup Prepare Node | 0 | Automatic: 200 GB | Automatic: Standard_F1s (cpu: 1, ram: 2 GB, disk: 1 | |
| UAA | Automatic: 2 | None | Automatic: Standard_F2s (cpu: 2, ram: 4 GB, disk: 3 | |
| Cloud Controller | Automatic: 2 | Automatic: 1 GB | Automatic: Standard_F2s (cpu: 2, ram: 4 GB, disk: 3 | |
| HAProxy | Automatic: 1 | None | Automatic: Standard_F1s (cpu: 1, ram: 2 GB, disk: 1 | |
| Router | Automatic: 3 | None | Automatic: Standard_F1s (cpu: 1, ram: 2 GB, disk: 1 | |

2. Ensure a **Standard** VM type is selected for the **Router** VM. The PAS deployment fails if you select a **Basic** VM type.
3. Retrieve the name(s) of your external ALB by navigating to the Azure portal, clicking **All resources**, and locating your **Load balancer** resource.

 **Note:** The Azure portal sometimes displays the names of resources with incorrect capitalization. Always use the Azure CLI to retrieve the correctly capitalized name of a resource. `az network lb list`

4. Locate the **Router** job in the **Resource Config** pane and enter the name of your external ALB in the field under **Load Balancers**.
5. Retrieve the name of your Diego SSH Load Balancer by navigating to the Azure portal, clicking **All resources**, and locating your **Load balancer** resource.
6. Locate the **Diego Brain** job in the **Resource Config** pane and enter the name of the Diego SSH Load Balancer in the field under **Load Balancers**.
7. Ensure that the **Internet Connected** checkboxes are deselected for all jobs.
8. Scale the number of instances as appropriate for your deployment.

 **Note:** For a high availability deployment of PCF on Azure, Pivotal recommends scaling the number of each PAS job to a minimum of three (3) instances. Using three or more instances for each job creates a sufficient number of availability sets and fault domains for your deployment. For more information, see [Reference Architecture for Pivotal Cloud Foundry on Azure](#).

Step 23: (Optional) Scale Down and Disable Resources

 **Note:** The **Resource Config** pane has fewer VMs if you are installing the [Small Footprint Runtime](#).

 **Note:** The Small Footprint Runtime does not default to a highly available configuration. It defaults to the minimum configuration. If you want to make the Small Footprint Runtime highly available, scale the **Compute**, **Router**, and **Database** VMs to **3** instances and scale the **Control** VM to **2** instances.

Pivotal Application Service (PAS) defaults to a highly available resource configuration. However, you may need to perform additional procedures to make your deployment highly available. See the [Zero Downtime Deployment and Scaling in CF](#) and the [Scaling Instances in PAS](#) topics for more information.

If you do not want a highly available resource configuration, you must scale down your instances manually by using the dropdowns under **Instances** for each job.

By default, PAS also uses an internal filestore and internal databases. If you configure PAS to use external resources, you can disable the corresponding system-provided resources in Ops Manager to reduce costs and administrative overhead.

Complete the following procedures to disable specific VMs in Ops Manager:

1. Click **Resource Config**.

2. If you configured PAS to use an external S3-compatible filestore, enter in **Instances** in the **File Storage** field.
3. If you selected **External** when configuring the UAA, System, and CredHub databases, edit the following fields:
 - **MySQL Proxy:** Enter in **Instances**.
 - **MySQL Server:** Enter in **Instances**.
 - **MySQL Monitor:** Enter in **Instances**.
4. If you disabled TCP routing, enter **Instances** in the **TCP Router** field.
5. Click **Save**.

Step 24: Download Stemcell

This step is only required if your Ops Manager does not already have the stemcell version required by PAS. For more information about importing stemcells, see [Importing and Managing Stemcells](#).

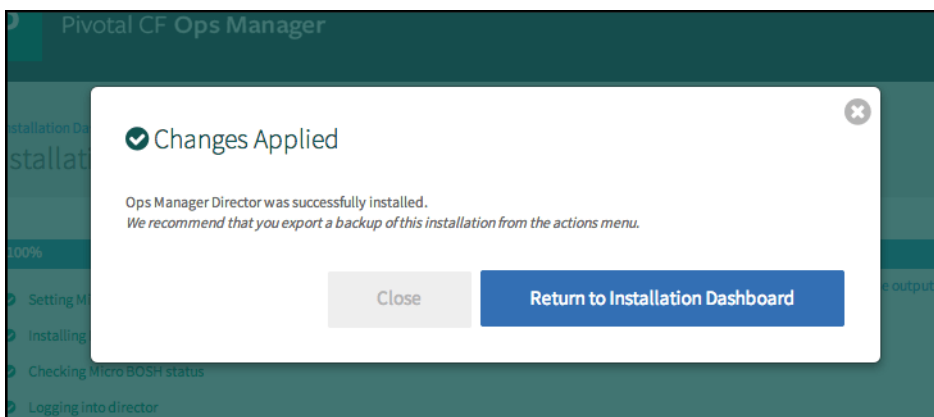

1. Open the [Stemcell product page](#) in the Pivotal Network. *Note, you may have to log in.*
2. Download the appropriate stemcell version targeted for your IaaS.
3. Navigate to **Stemcell Library** in the **Installation Dashboard**.
4. Click **Import Stemcell** to import the downloaded stemcell file.
5. When prompted, enable the Ops Manager product checkbox to stage your stemcell.
6. Click **Apply Stemcell to Products**.

Step 25: Complete the PAS Installation

1. Click the **Installation Dashboard** link to return to the Installation Dashboard.
2. Click **Apply Changes**. If the following ICMP error message appears, click **Ignore errors and start the install**.

The install process generally requires a minimum of 90 minutes to complete. The image shows the Changes Applied window that displays when the installation process successfully completes.

Installing PCF on Azure Using Terraform

This topic explains how to install Pivotal Cloud Foundry (PCF) on Microsoft Azure using Terraform.

To install PCF on Azure using Terraform, do the following:

1. Deploy Ops Manager. See [Deploying Ops Manager on Azure Using Terraform](#).
2. Configure BOSH Director on Azure Using Terraform. See [Configuring BOSH Director on Azure Using Terraform](#).
3. Deploy PAS. See [Deploying PAS on Azure Using Terraform](#).

Deploying Ops Manager on Azure Using Terraform

Page last updated:

This guide describes the preparation steps required to install Ops Manager on Azure using Terraform templates.

The Azure Terraform templates describe a set of Azure resources and properties. For more information about how Terraform creates resources in Azure, see the [Azure Provider](#) topic on the Terraform site.

You may also find it helpful to review different deployment options in the [Reference Architecture for Pivotal Cloud Foundry on Azure](#).

Prerequisites

In addition to fulfilling the prerequisites listed in the [Installing Pivotal Cloud Foundry on Azure](#) topic, ensure you have the following:

- The [Terraform CLI](#)
- In your Azure project, ensure you have completed the steps in [Preparing to Deploy Ops Manager on Azure Using Terraform](#) to create a service principal.

Step 1: Download Templates and Edit Variables File

Before you can run Terraform commands to provision infrastructure resources, you must download the Azure Terraform Templates and create a Terraform template variables file as described below:

1. On [Pivotal Network](#), navigate to the Pivotal Application Service (PAS) release.
2. Download the Azure Terraform ZIP file.
3. Extract the contents of the ZIP file.
4. Move the extracted folder to the `workspace` directory on your local machine.
5. On the command line, navigate to the directory. For example:

```
$ cd ~/workspace/pivotal-cf-terraforming-azure
```

6. Navigate to the `terraforming-pas` or `terraforming-pks` directory that contains the Terraform files for your runtime.
7. In the runtime directory, create a text file named `terraform.tfvars`.
8. Open the `terraform.tfvars` file and add the following:

```
subscription_id = "YOUR-SUBSCRIPTION-ID"
tenant_id       = "YOUR-TENANT-ID"
client_id       = "YOUR-CLIENT-ID"
client_secret   = "YOUR-CLIENT-SECRET"

env_name        = "YOUR-ENVIRONMENT-NAME"
env_short_name  = "YOUR-ENVIRONMENT-SHORTNAME"
location        = "YOUR-AZURE-LOCATION"
ops_manager_image_uri = "YOUR-OPS-MAN-IMAGE-URI"
dns_suffix      = "YOUR-DNS-SUFFIX"
vm_admin_username = "YOUR-ADMIN-USERNAME"
```

9. Edit the values in the file according to the table below.

| Value to replace | Guidance |
|-----------------------------------|--|
| <code>YOUR-SUBSCRIPTION-ID</code> | Enter the subscription ID of your Azure service principal. Terraform uses this ID when creating resources. |
| <code>YOUR-TENANT-ID</code> | Enter the tenant ID of your Azure service principal. Terraform uses this ID when creating resources. |
| <code>YOUR-CLIENT-ID</code> | Enter the client ID of your Azure service principal. Terraform uses this ID when creating |

| | |
|---|--|
| <code>YOUR-CLIENT-SECRET</code> | resources. Enter your Azure service client secret. Terraform requires this secret to create resources. |
| <code>YOUR-ENVIRONMENT-NAME</code> | Enter a name to use to identify resources in Azure. Terraform prepends the names of the resources it creates with this environment name. This environment variable is also used to name the Azure resource group created for the deployment. Example: <code>mypcf</code> . |
| <code>YOUR-ENVIRONMENT-SHORTNAME</code> | Enter a name to use when creating storage accounts in Azure. Must be a-z only and no longer than 10 characters. Example: <code>myazure</code> . |
| <code>YOUR-AZURE-LOCATION</code> | Enter the name of the Azure location in which you want Terraform to create resources. Example: <code>Central US</code> . |
| <code>YOUR-OPS-MAN-IMAGE-URI</code> | Enter the URL for the Ops Manager Azure image you want to boot. You can find this code in the PDF included with the Ops Manager release on Pivotal Network . |
| <code>YOUR-DNS-SUFFIX</code> | Enter a domain name to use as part of the system domain for your deployment. Terraform creates DNS records in Azure using <code>YOUR-ENVIRONMENT-NAME</code> and <code>YOUR-DNS-SUFFIX</code> . For example, if you enter <code>example.com</code> for your DNS suffix and have <code>pcf</code> as your environment name, Terraform creates DNS records at <code>pcf.example.com</code> . |
| <code>YOUR-ADMIN-USERNAME</code> | Enter the admin username you want to use for your Ops Manager deployment. |

Step 2: (Optional) Add Variables for Isolation Segment

Complete this section if you plan to deploy the Isolation Segment tile.

 **Note:** You can see the configurable options by opening the `variables.tf` file and looking for variables with default values.

Add the following variable to your `terraform.tfvars` file. This causes Terraform to create an additional HTTP load balancer and DNS record to use for the Isolation Segment tile.

```
isolation_segment = "true"
```

Step 3: Create Azure Resources with Terraform

Follow these steps to use the Terraform CLI to create resources on Azure:

1. From the directory that contains the Terraform files, run `terraform init` to initialize the directory based on the information you specified in the `terraform.tfvars` file.

```
$ terraform init
```

2. Run the following command to create the execution plan for Terraform.

```
$ terraform plan -out=plan
```

3. Run the following command to execute the plan from the previous step. It may take several minutes for Terraform to create all the resources in Azure.

```
$ terraform apply plan
```

Step 4: Create DNS Record

1. In a browser, navigate to the DNS provider for the DNS suffix you entered in your `terraform.tfvars` file.
2. Create a new NS (Name server) record for your system domain. Your system domain is `YOUR-ENVIRONMENT-NAME.YOUR-DNS-SUFFIX`.
3. In this record, enter the name servers included in `env_dns_zone_name_servers` from your Terraform output.

Next Steps

Proceed to the next step in the deployment, [Configuring BOSH Director on Azure Using Terraform](#).

Configuring BOSH Director on Azure Using Terraform

Page last updated:

This topic describes how to configure the BOSH Director tile within Ops Manager on Azure after [Deploying Ops Manager to Azure Using Terraform](#).

Note: You can also perform the procedures in this topic using the Ops Manager API. For more information, see the [Using the Ops Manager API](#) topic.

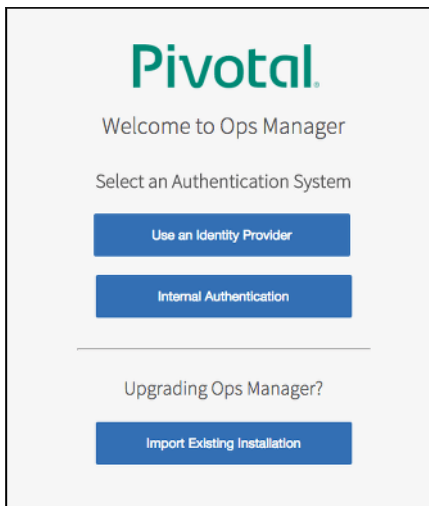

Prerequisite

To complete the procedures in this topic, you must have access to the output from when you ran `terraform apply` to create resources for this deployment. You can view this output at any time by running `terraform output`. You use the values in your Terraform output to configure the BOSH Director tile.

Step 1: Access Ops Manager

Note: For security, Ops Manager v1.7 and later require that you log in using a fully qualified domain name.

1. In a web browser, navigate to the fully qualified domain name (FQDN) of the BOSH Director. Use the `ops_manager_dns` value from running `terraform output`.
2. When Ops Manager starts for the first time, you must choose one of the following:
 - [Use an Identity Provider](#): If you use an Identity Provider, an external identity server maintains your user database.
 - [Internal Authentication](#): If you use Internal Authentication, Ops Manager maintains your user database.

Use an Identity Provider (IdP)

1. Log in to your IdP console and download the IdP metadata XML. Optionally, if your IdP supports metadata URL, you can copy the metadata URL instead of the XML.

2. Copy the IdP metadata XML or URL to the Ops Manager **Use an Identity Provider** login page.

Note: The same IdP metadata URL or XML is applied for the BOSH Director. If you use a separate IdP for BOSH, copy the metadata XML or URL from that IdP and enter it into the BOSH IdP Metadata text box in the Ops Manager login page.

3. Enter values for the fields listed below. Failure to provide values in these fields results in a `500` error.

Note: These attributes are case-sensitive.

- **SAML admin group:** Enter the name of the SAML group that contains all Ops Manager administrators.
- **SAML groups attribute:** Enter the groups attribute tag name with which you configured the SAML server.

4. Enter your **Decryption passphrase**. Read the **End User License Agreement**, and select the checkbox to accept the terms.

5. Your Ops Manager login page appears. Enter your username and password. Click **Login**.

6. Download your SAML Service Provider metadata (SAML Relying Party metadata) by navigating to the following URLs:

- **6a.** Ops Manager SAML service provider metadata: `https://OPS-MAN-FQDN:443/uaa/saml/metadata`
- **6b.** BOSH Director SAML service provider metadata: `https://BOSH-IP-ADDRESS:8443/saml/metadata`

Note: To retrieve your `BOSH-IP-ADDRESS`, navigate to the **BOSH Director** tile > **Status** tab. Record the **BOSH Director** IP address.

7. Configure your IdP with your SAML Service Provider metadata. Import the Ops Manager SAML provider metadata from Step 6a above to your IdP. If your IdP does not support importing, provide the values below.

- **Single sign on URL:** `https://OPS-MAN-FQDN:443/uaa/saml/SSO/alias/OPS-MAN-FQDN`
- **Audience URI (SP Entity ID):** `https://OP-MAN-FQDN:443/uaa`
- **Name ID:** Email Address
- SAML authentication requests are always signed

8. Import the BOSH Director SAML provider metadata from Step 6b to your IdP. If the IdP does not support an import, provide the values below.

- **Single sign on URL:** `https://BOSH-IP:8443/saml/SSO/alias/BOSH-IP`
- **Audience URI (SP Entity ID):** `https://BOSH-IP:8443`
- **Name ID:** Email Address
- SAML authentication requests are always signed

9. Return to the **BOSH Director** tile, and continue with the configuration steps below.

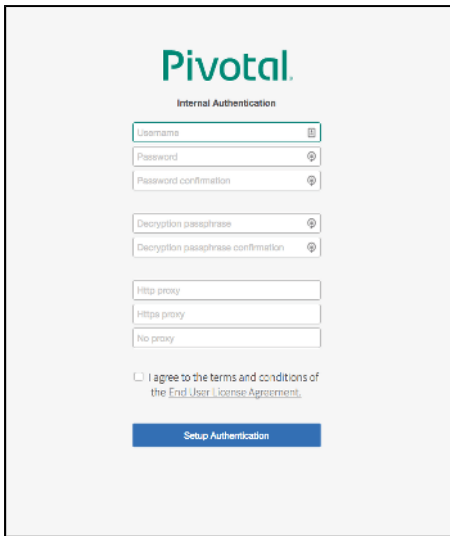

Internal Authentication

1. When redirected to the **Internal Authentication** page, do the following:

- Enter a **Username**, **Password**, and **Password confirmation** to create an Admin user.
- Enter a **Decryption passphrase** and the **Decryption passphrase confirmation**. This passphrase encrypts the Ops Manager datastore, and is not

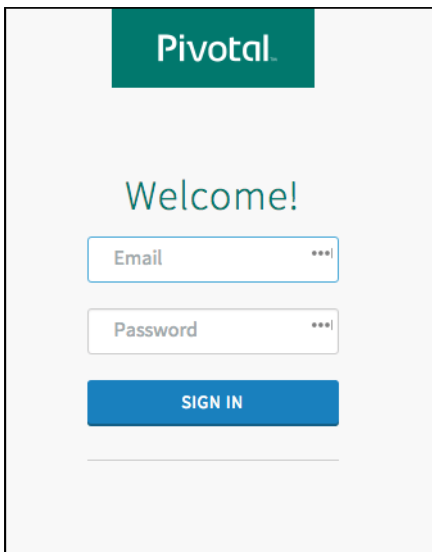

recoverable if lost.

- If you are using an **HTTP proxy** or **HTTPS proxy**, follow the instructions in the [Configuring Proxy Settings for the BOSH CPI](#) topic.
- Read the **End User License Agreement**, and select the checkbox to accept the terms.
- Click **Setup Authentication**.

The image shows the 'Internal Authentication' setup page in Pivotal. It features the Pivotal logo at the top. Below the logo, the title 'Internal Authentication' is centered. The form contains several input fields: 'Username', 'Password', 'Password confirmation', 'Decryption passphrase', and 'Decryption passphrase confirmation'. Each of these fields has a small icon to its right. Below these fields are three radio button options for 'Http proxy': 'Http proxy', 'Https proxy', and 'No proxy'. At the bottom of the form, there is a checkbox labeled 'I agree to the terms and conditions of the End User License Agreement'. A blue button labeled 'Setup Authentication' is positioned at the bottom center of the form.

2. Log in to Ops Manager with the Admin username and password that you created in the previous step.

The image shows the 'Welcome!' login page in Pivotal. It features the Pivotal logo at the top. Below the logo, the title 'Welcome!' is centered. The form contains two input fields: 'Email' and 'Password'. Each field has a small icon to its right. A blue button labeled 'SIGN IN' is positioned below the 'Password' field. A horizontal line is located at the bottom of the form.

Step 2: Azure Config Page

1. Click the **BOSH Director** tile.

2. Select **Azure Config**.

Installation Dashboard

Ops Manager Director

Settings Status Credentials

☐ Use Storage Accounts

Deployments Storage Account Name

Default Security Group*

SSH Public Key*

SSH Private Key*

Save

- Complete the following fields with information you obtained in the [Preparing to Deploy Ops Manager on Azure Using Terraform](#) topic.
 - Subscription ID:** Enter the ID of your Azure subscription.
 - Tenant ID:** Enter your `TENANT_ID`.
 - Application ID:** Enter the `APPLICATION_ID` that you created in the [Create an AAD Application](#) step of the *Preparing to Deploy Ops Manager on Azure Using Terraform* topic.
 - Client Secret:** Enter your `CLIENT_SECRET`.
- Complete the following fields:
 - Resource Group Name:** Enter the name of your resource group, which is exported from Terraform as the output `pcf_resource_group_name`.
 - BOSH Storage Account Name:** Enter the name of your storage account, which is exported from Terraform as the output `bosh_root_storage_account`.
- For **Cloud Storage Type**, select **Use Managed Disks**. For **Storage Account Type**, select **Premium_LRS** which corresponds to SSD-based storage.

See [Azure Managed Disks Overview](#) in the Microsoft documentation for more information.

Cloud Storage Type

☒ Use Managed Disks

Storage Account Type

Premium_LRS Storage Account Type to use with managed disks

☐ Use Storage Accounts

Warning: You can update your deployment from using storage accounts to using managed disks. However, after you select **Use Managed Disks** and deploy Ops Manager, you cannot change your deployment back to use storage accounts.

- For **Default Security Group**, enter the `bosh_deployed_vms_security_group_name` output from Terraform.
- For **SSH Public Key**, enter the `ops_manager_ssh_public_key` output from Terraform.
- For **SSH Private Key**, enter the `ops_manager_ssh_private_key` output from Terraform.
- For **Azure Environment**, select **Azure Commercial Cloud**.
- Click **Save**.

Step 3: Director Config Page

- Select **Director Config** to open the **Director Config** page.

Director Config

NTP Servers (comma delimited)*

time.nist.gov

JMX Provider IP Address

Bosh HM Forwarder IP Address

☐ Enable VM Resurrector Plugin

☐ Enable Post Deploy Scripts

☐ Recreate all VMs

This will force BOSH to recreate all VMs on the next deploy. Persistent disk will be preserved

☐ Enable bosh deploy retries

This will attempt to re-deploy a failed deployment up to 5 times.

☐ Keep Unreachable Director VMs

- In the **NTP Servers (comma delimited)** field, enter a comma-separated list of valid NTP servers.

Note: The NTP server configuration only updates after VM recreation. Ensure that you select the **Recreate all VMs** checkbox if you modify the value of this field.

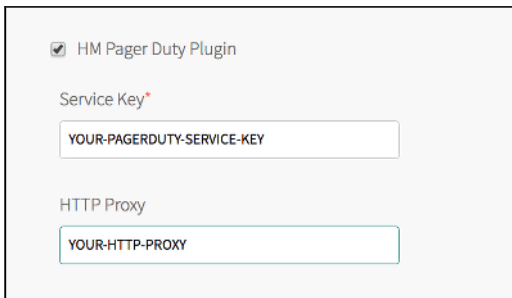

- Leave the **JMX Provider IP Address** field blank.

Note: BOSH-reported system metrics are available in the Loggregator Firehose by default. Therefore, if you continue to use PCF JMX Bridge for consuming them outside of the Firehose, you may receive duplicate data. To prevent this, leave the **JMX Provider IP Address** field blank.

4. Leave the **Bosh HM Forwarder IP Address** field blank.

Note: BOSH-reported system metrics are available in the Loggregator Firehose by default. Therefore, if you continue to use the BOSH HM Forwarder for consuming them, you may receive duplicate data. To prevent this, leave the **Bosh HM Forwarder IP Address** field blank.

5. Select the **Enable VM Resurrector Plugin** checkbox to enable the Ops Manager Resurrector functionality and increase Pivotal Application Service (PAS) availability.
6. Select **Enable Post Deploy Scripts** to run a post-deploy script after deployment. This script allows the job to execute additional commands against a deployment.
7. Select **Recreate all VMs** to force BOSH to recreate all VMs on the next deploy. This process does not destroy any persistent disk data.
8. Select **Enable bosh deploy retries** if you want Ops Manager to retry failed BOSH operations up to five times.
9. (Optional) Disable **Allow Legacy Agents** if all of your tiles have stemcells v3468 or later. Disabling the field will allow Ops Manager to implement TLS secure communications.
10. Select **Keep Unreachable Director VMs** if you want to preserve BOSH Director VMs after a failed deployment for troubleshooting purposes.
11. Select **HM Pager Duty Plugin** to enable Health Monitor integration with PagerDuty.

☒ HM Pager Duty Plugin

Service Key*

YOUR-PAGERDUTY-SERVICE-KEY

HTTP Proxy

YOUR-HTTP-PROXY

- **Service Key:** Enter your API service key from PagerDuty.
- **HTTP Proxy:** Enter an HTTP proxy for use with PagerDuty.

12. Select **HM Email Plugin** to enable Health Monitor integration with email.

☒ HM Email Plugin

Host*

Port*

Domain*

From*

Recipients*

Username

Password

☒ Enable TLS

- **Host:** Enter your email hostname.
- **Port:** Enter your email port number.
- **Domain:** Enter your domain.
- **From:** Enter the address for the sender.
- **Recipients:** Enter comma-separated addresses of intended recipients.
- **Username:** Enter the username for your email server.
- **Password:** Enter the password for your email server.
- **Enable TLS:** Select this checkbox to enable Transport Layer Security.

- For **CredHub Encryption Provider**, you can choose whether BOSH CredHub stores its encryption key internally on the BOSH Director and CredHub VM, or in an external hardware security module (HSM). The HSM option is more secure.

Before configuring an HSM encryption provider in the **Director Config** pane, you must follow the procedures and collect information described in [Preparing CredHub HSMs for Configuration](#).

 **Note:** After you deploy Ops Manager with an HSM encryption provider, you cannot change BOSH CredHub to store encryption keys internally.

CredHub Encryption Provider

☒ Internal
 ☐ Luna HSM

Encryption Key Name*

Provider Partition*

Provider Partition Password*

Provider Client Certificate*

Provider Client Certificate Private Key*

HSM Host Address*

HSM Port Address*

Partition Serial Number*

HSM Certificate*

- **Internal:** Select this option for internal CredHub key storage. This option is selected by default and requires no additional configuration.
- **Luna HSM:** Select this option to use a SafeNet Luna HSM as your permanent CredHub encryption provider, and fill in the following fields:
 1. **Encryption Key Name:** Any name to identify the key that the HSM uses to encrypt and decrypt the CredHub data. Changing this key name after you deploy Ops Manager can cause service downtime.
 2. **Provider Partition:** The partition that stores your encryption key. Changing this partition after you deploy Ops Manager could cause service downtime. For this value and the ones below, use values gathered in [Preparing CredHub HSMs for Configuration](#).
 3. **Provider Partition Password**
 4. **Provider Client Certificate:** The certificate that validates the identity of the HSM when CredHub connects as a client.
 5. **Provider Client Certificate Private Key**
 6. **HSM Host Address**
 7. **HSM Port Address:** If you do not know your port address, enter `1792`.
 8. **Partition Serial Number**
 9. **HSM Certificate:** The certificate that the HSM presents to CredHub to establish a two-way mTLS connection.

14. Select a **Blobstore Location** to either configure the blobstore as an internal server or an external endpoint. Because the internal server is unscalable and less secure, Pivotal recommends that you configure an external blobstore.

 **Note:** After you deploy Ops Manager, you cannot change the blobstore location.

Blobstore Location

☒ Internal
☐ S3 Compatible Blobstore

S3 Endpoint*

Bucket Name*

Access Key*

Secret Key*

☒ V2 Signature
☐ V4 Signature

Region*

☐ GCS Blobstore

Bucket Name*

Storage Class*

Regional

Service Account Key*

- o **Internal:** Select this option to use an internal blobstore. Ops Manager creates a new VM for blob storage. No additional configuration is required.
- o **S3 Compatible Blobstore:** Select this option to use an external S3-compatible endpoint. Follow the procedures in [Sign up for Amazon S3](#) and [Creating a Bucket](#) in the AWS documentation. When you have created an S3 bucket, complete the following steps:
 1. **S3 Endpoint:** Navigate to the [Regions and Endpoints](#) topic in the AWS documentation.
 - a. Locate the endpoint for your region in the **Amazon Simple Storage Service (S3)** table and construct a URL using your region's endpoint. For example, if you are using the `us-west-2` region, the URL you create would be `https://s3-us-west-2.amazonaws.com`. Enter this URL into the **S3 Endpoint** field.
 - b. On a command line, run `ssh ubuntu@OPS-MANAGER-FQDN` to SSH into the Ops Manager VM. Replace `OPS-MANAGER-FQDN` with the fully qualified domain name of Ops Manager.
 - c. Copy the custom public CA certificate you used to sign the S3 endpoint into `/etc/ssl/certs` on the Ops Manager VM.
 - d. On the Ops Manager VM, run `sudo update-ca-certificates -f -v` to import the custom CA certificate into the Ops Manager VM truststore.

 **Note:** You must also add this custom CA certificate into the **Trusted Certificates** field in the **Security** page. See [Security Page](#) for instructions.

2. **Bucket Name:** Enter the name of the S3 bucket.
3. **Access Key** and **Secret Key:** Enter the keys you generated when creating your S3 bucket.
4. Select **V2 Signature** or **V4 Signature**. If you select **V4 Signature**, enter your **Region**.

 **Note:** AWS recommends using Signature Version 4. For more information about AWS S3 Signatures, see [Authenticating Requests](#) in the AWS documentation.

- **Enable TLS:** Select this checkbox to enable TLS.

 **Note:** If you are using Linux stemcells, make sure you have configured [Linux stemcell v3586.16 or later](#) for all tiles before enabling TLS.

 **Note:** If you are using PAS for Windows 2016, make sure you have configured [Windows stemcell v1709.10 or later](#) for all tiles before enabling TLS.

- **GCS Blobstore:** Select this option to use an external GCS endpoint. To create a GCS bucket, you must have a GCS account. Follow the procedures in [Creating Storage Buckets](#) in the GCS documentation to create a GCS bucket. When you have created a GCS bucket, complete the following steps:
 1. **Bucket Name:** Enter the name of your GCS bucket.
 2. **Storage Class:** Select the storage class for your GCS bucket. See [Storage Classes](#) in the GCP documentation for more information.
 3. **Service Account Key:** Follow the steps in the [Set up an IAM Service Account](#) section of *Preparing to Deploy Ops Manager on GCP Manually* to download a JSON file with a private key. Enter the contents of the JSON file into the field.

15. For **Database Location**, select **Internal**.

16. (Optional) **Director Workers** sets the number of workers available to execute Director tasks. This field defaults to `5`.

17. (Optional) **Max Threads** sets the maximum number of threads that the BOSH Director can run simultaneously. Pivotal recommends that you leave the field blank to use the default value, unless doing so results in rate limiting or errors on your IaaS.

18. (Optional) To add a custom URL for your BOSH Director, enter a valid hostname in **Director Hostname**. You can also use this field to configure a load balancer in front of your BOSH Director. For more information, see [How to set up a load balancer in front of BOSH Director](#) in the Pivotal Knowledge Base.

 **Warning:** In Ops Manager v2.2.7 and earlier, if you change the **Director Hostname** after your initial deployment, VMs become unavailable. This causes downtime. To restore VM availability, enable **Recreate All VMs** and redeploy. This issue is resolved in [Ops Manager v2.2.8](#) and later.

19. (Optional) Enter your list of comma-separated **Excluded Recursors** to declare which IP addresses and ports should not be used by the DNS server.

20. (Optional) To disable BOSH DNS, select the **Disable BOSH DNS server for troubleshooting purposes** checkbox. For more information about the BOSH DNS service discovery mechanism, see [BOSH DNS Enabled by Default](#) in the Ops Manager v2.2 Release Notes.

 **Breaking Change:** Do not disable BOSH DNS without consulting Pivotal Support.

21. (Optional) To set a custom banner that users see when logging in to the Director using SSH, enter text in the **Custom SSH Banner** field.

☐ Disable BOSH DNS server for troubleshooting purposes

Custom SSH Banner

22. (Optional) Enter your comma-separated custom **Identification Tags**. For example, `iaas:foundation1, hello:world`. You can use the tags to identify your foundation when viewing VMs or disks from your IaaS.

 **Note:** Azure has limited space for identification tags. Pivotal recommends entering no more than five tags.

23. Click **Save**.

Step 4: Create Networks Page

Select **Create Networks** and follow the procedures in this section to add the network configuration you created for your VPC.

Create the Infrastructure Network

1. Click **Add Network**.
 2. (Optional) Select **Enable ICMP checks** to enable ICMP on your networks. Ops Manager uses ICMP checks to confirm that components within your network are reachable.
 3. For **Name**, enter the name of the network you want to create. For example, `infrastructure`.
 4. Under **Subnets**, complete the following fields:
 - **Azure Network Name:** Enter `NETWORK-NAME/SUBNET-NAME`, where `NETWORK-NAME` is the `network_name` output from Terraform and `SUBNET-NAME` is the `infrastructure_subnet_name` output from Terraform.
-  **Note:** The Azure portal sometimes displays the names of resources with incorrect capitalization. Always use the Azure CLI to retrieve the correctly capitalized name of a resource.
- **CIDR:** Enter the CIDR listed under `infrastructure_subnet_cidrs` output from Terraform. For example, `10.0.8.0/26`.
 - **Reserved IP Ranges:** Enter the first nine IP addresses of the subnet. For example, `10.0.8.1-10.0.8.9`.
 - **DNS:** Enter `168.63.129.16`.
 - **Gateway:** Enter the first IP address of the subnet. For example, `10.0.8.1`.

Create Networks

Warning: Pivotal recommends keeping the IP settings throughout the life of your installation. Ops Manager may prevent you from changing them in the future.
Contact Pivotal support for help completing such a change.

Verification Settings

☐ Enable ICMP checks

Networks

One or many IP ranges upon which your products will be deployed

▼ infrastructure 

Name*

Subnets 

Azure Network Name*

CIDR*

Reserved IP Ranges

DNS*

Gateway*

5. Click **Save**.

 **Note:** After you deploy Ops Manager, you add subnets with overlapping Availability Zones to expand your network. For more information about configuring additional subnets, see [Expanding Your Network with Additional Subnets](#).

Create the PAS Network

- Click **Add Network**.
- (Optional) Select **Enable ICMP checks** to enable ICMP on your networks. Ops Manager uses ICMP checks to confirm that components within your network are reachable.
- For **Name**, enter the name of the network you want to create. For example, `pas`.
- Under **Subnets**, complete the following fields:
 - Azure Network Name:** Enter `NETWORK-NAME/SUBNET-NAME`, where `NETWORK-NAME` is the `network_name` output from Terraform and `SUBNET-NAME` is the `pas_subnet_name` output from Terraform.
 - CIDR:** Enter the CIDR listed under `pas_subnet_cidrs` output from Terraform. For example, `10.0.0.0/22`.
 - Reserved IP Ranges:** Enter the first nine IP addresses of the subnet. For example, `10.0.0.1-10.0.0.9`.
 - DNS:** Enter `168.63.129.16`.
 - Gateway:** Enter the first IP address of the subnet. For example, `10.0.0.1`.

▼ pas

Name*

DNS*

168.63.129.16

Gateway*

10.0.12.1

5. Click **Save**.

Create the Services Network

1. (Optional) Select **Enable ICMP checks** to enable ICMP on your networks. Ops Manager uses ICMP checks to confirm that components within your network are reachable.
2. For **Name**, enter the name of the network you want to create. For example, `services`.
3. Under **Subnets**, complete the following fields:
 - **Azure Network Name:** Enter `NETWORK-NAME/SUBNET-NAME`, where `NETWORK-NAME` is the `network_name` output from Terraform and `SUBNET-NAME` is the `services_subnet_name` output from Terraform.
 - **CIDR:** Enter the CIDR listed under `services_subnet_cidrs` output from Terraform. For example, `10.0.4.0/22`.
 - **Reserved IP Ranges:** Enter the first nine IP addresses of the subnet. For example, `10.0.4.1-10.0.4.9`.
 - **DNS:** Enter `168.63.129.16`.
 - **Gateway:** Enter the first IP address of the subnet. For example, `10.0.4.1`.

4. Click **Save**. If you do not have **Enable ICMP checks** selected, you may see red warnings which you can safely ignore.

Step 5: Assign Networks Page

1. Select **Assign Networks**.

Network Assignments

Network

infrastructure

Save

2. Use the dropdown to select the `infrastructure` network for your BOSH Director.
3. Click **Save**.

Step 6: Security Page

[illegible]

1. Select **Security**.
2. In **Trusted Certificates**, enter your custom certificate authority (CA) certificates to insert into your organization's certificate trust chain. This feature enables all BOSH-deployed components in your deployment to trust custom root certificates.

To enter multiple certificates, paste your certificates one after the other. For example, format your certificates like the following:

```

-----BEGIN CERTIFICATE-----
ABCEDEFGH12345678ABCEDEFGH12345678ABCEDEFGH12345678AB
EFGH12345678ABCEDEFGH12345678ABCEDEFGH12345678ABCEDEF
GH12345678ABCEDEFGH12345678ABCEDEFGH12345678...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
BCDEFGH12345678ABCEDEFGH12345678ABCEDEFGH12345678ABB
EFGH12345678ABCEDEFGH12345678ABCEDEFGH12345678ABCEDEF
GH12345678ABCEDEFGH12345678ABCEDEFGH12345678...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
CDEFGH12345678ABCEDEFGH12345678ABCEDEFGH12345678ABBB
EFGH12345678ABCEDEFGH12345678ABCEDEFGH12345678ABCEDEF
GH12345678ABCEDEFGH12345678ABCEDEFGH12345678...
-----END CERTIFICATE-----

```

 Note: If you want to use Docker Registries for running app instances in Docker containers, enter the certificate for your private Docker Registry in this field. See [Using Docker Registries](#) for more information on running app instances in PAS using Docker Registries.

3. Choose **Generate passwords** or **Use default BOSH password**. Pivotal recommends that you use the **Generate passwords** option for greater security.
4. Click **Save**. To view your saved Director password, click the **Credentials** tab.

Step 7: Syslog Page

1. Select **Syslog**.

Syslog

Do you want to configure Syslog for Bosh Director?

☐ No
 ☒ Yes

Address*

The address or host for the syslog server

Port*

Transport Protocol*

TCP

☐ Enable TLS

Permitted Peer*

SSL Certificate*

Save

- (Optional) Select **Yes** to send BOSH Director system logs to a remote server.
- In the **Address** field, enter the IP address or DNS name for the remote server.
- In the **Port** field, enter the port number that the remote server listens on.
- In the **Transport Protocol** dropdown menu, select **TCP**, **UDP**, or **REL**. This selection determines which transport protocol is used to send the logs to the remote server.
- (Optional) Pivotal strongly recommends that you enable TLS encryption when forwarding logs as they may contain sensitive information. For example, these logs may contain cloud provider credentials. To enable TLS, perform the following steps.
 - In the **Permitted Peer** field, enter either the name or SHA1 fingerprint of the remote peer.
 - In the **SSL Certificate** field, enter the SSL certificate for the remote server.
- Click **Save**.

Step 8: Resource Config Page

- Select **Resource Config**.

Resource Config

| JOB | INSTANCES | PERSISTENT DISK TYPE | VM TYPE | LOAD BALANCERS | INTERNET CONNECTED |
|------------------------|--------------|----------------------|---|----------------|--------------------------|
| Ops Manager Director | Automatic: 1 | Automatic: 50 GB | Automatic: Standard_DS2_v2 (cpu: 2, ram | | <input type="checkbox"/> |
| Master Compilation Job | Automatic: 4 | None | Automatic: Standard_F4s (cpu: 4, ram: 8 G | | <input type="checkbox"/> |

Save

- Adjust any values as necessary for your deployment. Under the **Instances**, **Persistent Disk Type**, and **VM Type** fields, choose **Automatic** from the dropdown to allocate the recommended resources for the job. If the **Persistent Disk Type** field reads **None**, the job does not require persistent disk space.

 **Note:** Pivotal recommends provisioning a BOSH Director VM with at least 8 GB memory.

 **Note:** If you set a field to **Automatic** and the recommended resource allocation changes in a future version, Ops Manager automatically uses the new recommended allocation.

 **Note:** If you install PAS for Windows, provision your **Master Compilation Job** with at least 100 GB of disk space.

- (Optional) For **Load Balancers**, enter your Azure application gateway name for each associated job. To create an application gateway, follow the procedures in [Create an application gateway with SSL termination using Azure PowerShell](#) from the Azure documentation. When you create the application gateway, associate the gateway's IP with your system domain.
- Click **Save**.

Step 9: (Optional) Add Custom VM Extensions

Use the Ops Manager API to add custom properties to your VMs such as associated security groups and load balancers. For more information, see [Managing Custom VM Extensions](#).

Step 10: Complete the BOSH Director Installation

- Click the **Installation Dashboard** link to return to the Installation Dashboard.
- Click **Apply Changes**. If the following ICMP error message appears, click **Ignore errors and start the install**.

PCF Ops Manager

pivotal-cf

 Please review the errors below

- Cannot reach gateway with IP 10.0.16.1 (ignorable if ICMP is disabled)
- Cannot reach DNS with IP 10.0.0.2 (ignorable if ICMP is disabled)

Ignore errors and start the install

Stop and fix errors

- BOSH Director installs. This may take a few moments. When the installation process successfully completes, the **Changes Applied** window appears.

Next Steps

After you complete this procedure, follow the procedures in [Deploying PAS on Azure Using Terraform](#).

Deploying PAS on Azure Using Terraform

Page last updated:

This topic describes how to install and configure Pivotal Application Service (PAS) on Azure.

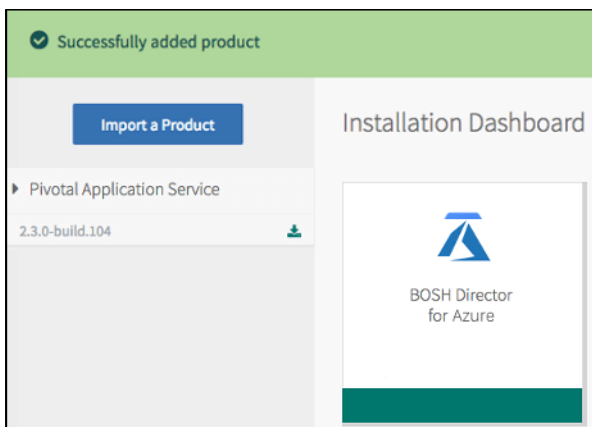

Before you perform the procedures in this topic, you must have completed the procedures in [Deploying Ops Manager to Azure Using Terraform](#), the [Launching a BOSH Director Instance on Azure Using Terraform](#) topic, and the [Configuring BOSH Director on Azure Using Terraform](#) topic.

Note: If you plan to [install the PCF IPsec add-on](#), you must do so before installing any other tiles. Pivotal recommends installing IPsec immediately after Ops Manager, and before installing the Pivotal Application Service (PAS) tile.

Note: The Azure portal sometimes displays the names of resources with incorrect capitalization. Always use the Azure CLI to retrieve the correctly capitalized name of a resource.

Step 1: Add PAS to Ops Manager

1. If you have not already downloaded PAS, log in to [Pivotal Network](#), and click on PAS.
2. From the **Releases** drop-down, select the release to install and choose one of the following:
 - a. Click PAS to download the PAS `.pivotal` file.
 - b. Click **PCF Small Footprint PAS** to download the Small Footprint Runtime `.pivotal` file. For more information, see [Getting Started with Small Footprint Runtime](#).
3. Navigate to the Ops Manager Installation Dashboard.
4. Click **Import a Product** and select the downloaded `.pivotal` file. For more information, refer to the [Adding and Deleting Products](#) topic.
5. Click the plus button next to the imported tile to add it to the Installation Dashboard.

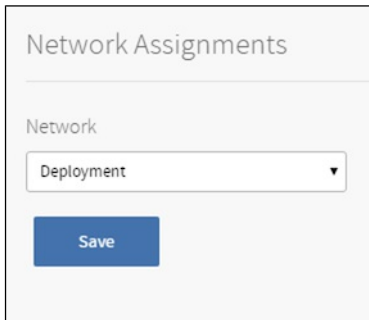

6. Click the PAS tile in the Installation Dashboard.

Step 2: Assign Networks

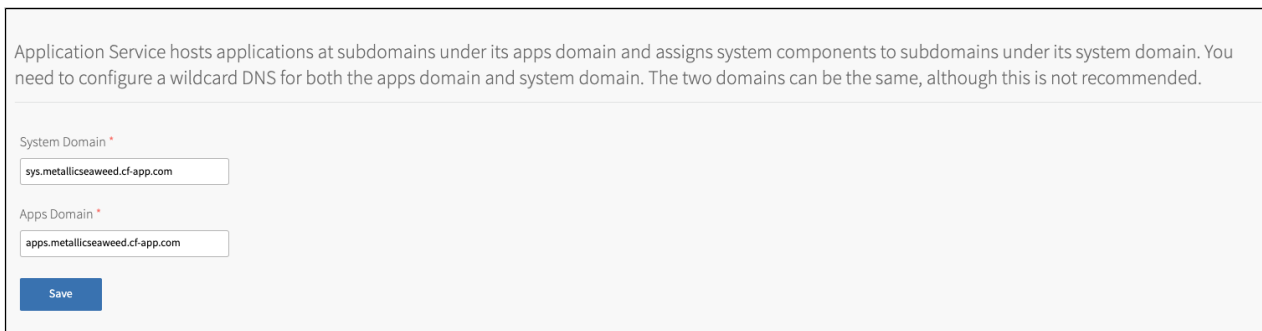

1. Select **Assign Networks**.
2. From the **Network** dropdown, select the network on which you want to run PAS.

3. Click **Save**.

Step 3: Configure Domains

1. Select **Domains**.

2. Enter the system and application domains.
 - For **System Domain**, enter the value of `sys_domain` from the Terraform output. This defines your target when you push apps to PAS.
 - For **Apps Domain**, enter the value of `apps_domain` from the Terraform output. This defines where PAS should serve your apps.

 **Note:** You configured a wildcard DNS record for these domains in an earlier step.

3. Click **Save**.

Step 4: Configure Networking

1. Select **Networking**.
2. Leave the **Router IPs**, **SSH Proxy IPs**, **HAProxy IPs**, and **TCP Router IPs** fields blank. You do not need to complete these fields when deploying PCF to Azure.

 **Note:** You specify load balancers in the **Resource Config** section of PAS later on in the installation process. See the [Configuring Resources](#) section.

3. Under **Certificates and Private Key for HAProxy and Router**, you must provide at least one **Certificate and Private Key** name and certificate keypair for HAProxy and Gorouter. The HAProxy and Gorouter are enabled to receive TLS communication by default. You can configure multiple certificates for HAProxy and Gorouter.
 - a. Click the **Add** button to add a name for the certificate chain and its private keypair. This certificate is the default used by Gorouter and HAProxy.

Certificates and Private Keys for HAProxy and Router

Add

▼ example-cert

Name *

example-cert

A human-readable name describing the use of this certificate.

Certificate and Private Key for HAProxy and Router *

-----BEGIN CERTIFICATE-----

MIIE...

-----END CERTIFICATE-----

-----BEGIN RSA PRIVATE KEY-----

MIIE...

-----END RSA PRIVATE KEY-----

Generate RSA Certificate

▼ example-cert-2

Name *

example-cert-2

Certificate and Private Key for HAProxy and Router *

-----BEGIN CERTIFICATE-----

MIIE...

-----END CERTIFICATE-----

-----BEGIN RSA PRIVATE KEY-----

MIIE...

-----END RSA PRIVATE KEY-----

You can either provide a certificate signed by a Certificate Authority (CA) or click on the **Generate RSA Certificate** link to generate a self-signed certificate in Ops Manager.

- b. If you want to configure multiple certificates for HAProxy and Gorouter, click the **Add** button and fill in the appropriate fields for each additional certificate keypair.

For details about generating certificates in Ops Manager for your wildcard system domains, see the [Providing a Certificate for Your SSL/TLS Termination Point](#) topic.

Note: If you configured Ops Manager Front End without a certificate, you can use this new certificate to complete Ops Manager configuration. To configure your Ops Manager Front End certificate, see *Configure Front End* in [Preparing to Deploy Ops Manager on GCP Manually](#).

Note: Ensure that you add any certificates that you generate in this pane to your infrastructure load balancer.

4. (Optional) When validating client requests using mutual TLS, the Gorouter trusts multiple certificate authorities (CAs) by default. If you want to configure the Gorouter and HAProxy to trust additional CAs, enter your CA certificates under **Certificate Authorities Trusted by Router and HAProxy**. All CA certificates should be appended together into a single collection of PEM-encoded entries.

Certificate Authorities Trusted by Router and HAProxy

In addition to well-known, public CAs, and those trusted via the BOSH trusted certificates collection, these certificates can be used to validate the certificates from incoming client requests. All CA certificates should be appended together into a single collection of PEM-encoded entries.

- In the **Minimum version of TLS supported by HAProxy and Router** field, select the minimum version of TLS to use in HAProxy and Gorouter communications. HAProxy and Gorouter use TLS v1.2 by default. If you need to accommodate clients that use an older version of TLS, select a lower minimum version. For a list of TLS ciphers supported by the Gorouter, see [Securing Traffic into Cloud Foundry](#).

Minimum version of TLS supported by HAProxy and Router*

- ☐ TLSv1.0
- ☐ TLSv1.1
- ☒ TLSv1.2

- Configure **Logging of Client IPs in CF Router**. The **Log client IPs** option is set by default. To comply with the General Data Protection Regulation (GDPR), select one of the following options to disable logging of client IP addresses:

- If your load balancer exposes its own source IP address, disable logging of the `X-Forwarded-For` HTTP header only.
- If your load balancer exposes the source IP of the originating client, disable logging of both the source IP address and the `X-Forwarded-For` HTTP header.

Logging of Client IPs in CF Router*

- ☒ Log client IPs
- ☐ Disable logging of X-Forwarded-For header only
- ☐ Disable logging of both source IP and X-Forwarded-For header
- To comply with GDPR, select one of the options to disable logging of client IPs. If the source IP exposed by your load balancer is its own, choose to disable logging of XFF header only. If the source IP exposed by your load balancer is that of the downstream client, choose to disable logging of the source IP also.

- Under **Configure support for the X-Forwarded-Client-Cert header**, configure PCF handles `x-forwarded-client-cert` (XFCC) HTTP headers based on where TLS is terminated for the first time in your deployment.

Configure support for the X-Forwarded-Client-Cert header. This header can be used by applications to verify the requester via mutual TLS. The option you should select depends upon where you will be terminating the TLS connection for the first time. *

- ☒ TLS terminated for the first time at infrastructure load balancer
- ☐ TLS terminated for the first time at HAProxy
- ☐ TLS terminated for the first time at the Router

The following table

indicates which option to choose based on your deployment layout.

| If your deployment is configured as follows: | Then select the following option: | Additional notes: |
|--|--|---|
| <ul style="list-style-type: none"> The Load Balancer is terminating TLS, and Load balancer is configured to put the client certificate from a mutual authentication TLS handshake into the X-Forwarded-Client-Cert HTTP header | TLS terminated for the first time at infrastructure load balancer (default). | Both HAProxy and the Gorouter forward the XFCC header when included in the request. |
| <ul style="list-style-type: none"> The Load Balancer is configured to pass through the TLS handshake via TCP to | TLS terminated for | HAProxy sets the XFCC header with the client certificate received in the TLS handshake. The Gorouter forwards the header. |

| | | |
|--|--|---|
| the instances of HAProxy, and o HAProxy instance count is > 0 | the first time at HAProxy. |  Breaking Change: In the Router behavior for Client Certificates field, you cannot select the Router does not request client certificates option. |
| o The Load Balancer is configured to pass through the TLS handshake via TCP to instances of the Gorouter | TLS terminated for the first time at the Gorouter. | <p>The Gorouter strips the XFCC header if it is included in the request and forwards the client certificate received in the TLS handshake in a new XFCC header.</p> <p>If you have deployed instances of HAProxy, app traffic bypasses those instances in this configuration. If you have also configured your load balancer to route requests for ssh directly to the Diego Brain, consider reducing HAProxy instances to 0.</p>  Breaking Change: In the Router behavior for Client Certificates field, you cannot select the Router does not request client certificates option. |

For a description of the behavior of each configuration option, see [Forward Client Certificate to Applications](#).

8. To configure HAProxy to handle client certificates, select one of the following options in the **HAProxy behavior for Client Certificate Validation** field.

HAProxy behavior for Client Certificate Validation*

- ☒ HAProxy does not request client certificates.
- ☐ HAProxy requests but does not require client certificates. This option is necessary if you want to enable mTLS for applications and TLS is terminated for the first time at HAProxy

- o **HAProxy does not request client certificates.** This option requires mutual authentication, which makes it incompatible with XFCC option **TLS terminated for the first time at HAProxy**. HAProxy does not request client certificates, so the client does not provide them and no validation occurs. This is the default configuration.
- o **HAProxy requests but does not require client certificates.** The HAProxy requests client certificates in TLS handshakes, validates them when presented, but does not require them.

 **warning:** Upon upgrade, PAS will fail to receive requests if your load balancer is configured to present a client certificate in the TLS handshake with HAProxy but HAProxy has not been configured with the certificate authority used to sign it. To mitigate this issue, select **HAProxy does not request client certificates** in the **Networking** pane or configure the HAProxy with the appropriate CA.

9. To configure Gorouter behavior for handling client certificates, select one of the following options in the **Router behavior for Client Certificate Validation** field.

Router behavior for Client Certificate Validation*

- ☐ Router does not request client certificates. This option is incompatible with XFCC options "TLS terminated for the first time at HAProxy" and "TLS terminated for the first time at the Router" because these options require mutual authentication.
- ☒ Router requests but does not require client certificates.
- ☐ Router requires client certificates.

- o **Router does not request client certificates.** This option is incompatible with the XFCC configuration options **TLS terminated for the first time at HAProxy** and **TLS terminated for the first time at the Router** in PAS because these options require mutual authentication. As client certificates are not requested, client will not provide them, and thus validation of client certificates will not occur.
- o **Router requests but does not require client certificates.** The Gorouter requests client certificates in TLS handshakes, validates them when presented, but does not require them. This is the default configuration.
- o **Router requires client certificates.** The Gorouter validates that the client certificate is signed by a Certificate Authority that the Gorouter trusts. If the Gorouter cannot validate the client certificate, the TLS handshake fails.

 **warning:** Requests to the platform will fail upon upgrade if your load balancer is configured with client certificates and the Gorouter does not have the certificate authority. To mitigate this issue, select **Router does not request client certificates** for **Router behavior for Client**

Certificate Validation in the Networking pane.

- In the **TLS Cipher Suites for Router** field, review the TLS cipher suites for TLS handshakes between Gorouter and front-end clients such as load balancers or HAProxy. The default value for this field is `ECDHE-RSA-AES128-GCM-SHA256:TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384`. If you want to modify the default configuration, use an ordered, colon-delimited list of Golang-supported TLS cipher suites in the OpenSSL format. Operators should verify that the ciphers are supported by any clients or front-end components that will initiate TLS handshakes with Gorouter. For a list of TLS ciphers supported by Gorouter, see [Securing Traffic into Cloud Foundry](#).

TLS Cipher Suites for Router *

ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384

Verify that every client participating in TLS handshakes with Gorouter has at least one cipher suite in common with Gorouter.

 **Note:** Specify cipher suites that are supported by the versions configured in the **Minimum version of TLS supported by HAProxy and Router** field.

- In the **TLS Cipher Suites for HAProxy** field, review the TLS cipher suites for TLS handshakes between HAProxy and its clients such as load balancers and Gorouter. The default value for this field is the following:
`DHE-RSA-AES128-GCM-SHA256:DHE-RSA-AES256-GCM-SHA384:ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384` If you want to modify the default configuration, use an ordered, colon-delimited list of TLS cipher suites in the OpenSSL format. Operators should verify that the ciphers are supported by any clients or front-end components that will initiate TLS handshakes with HAProxy.

TLS Cipher Suites for HAProxy *

DHE-RSA-AES128-GCM-SHA256:DHE-RSA-AES256-GCM-SHA384:ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384

Verify that every client participating in TLS handshakes with HAProxy has at least one cipher suite in common with HAProxy.

 **Note:** Specify cipher suites that are supported by the versions configured in the **Minimum version of TLS supported by HAProxy and Router** field.

- Under **HAProxy forwards requests to Router over TLS**, select **Enable** or **Disable** based on your deployment layout.

HAProxy forwards requests to Router over TLS. When enabled, HAProxy will forward all requests to the Router over TLS. HAProxy will use the CA provided to verify the certificates provided by the Router. *

☒ Enable

Certificate Authority for HAProxy Backend *

You need to provide a certificate authority for the certificate and key provided in the "Certificate and Private Key for HAProxy and Router" field. HAProxy will verify those certificates using this CA when establishing a connection. If you generated that certificate and key using the "Generate RSA Certificate" feature, then your CA is the Ops Manager CA, and can be found by visiting the "/api/v0/certificate_authorities" API endpoint.

☐ Disable

◦ Enable HAProxy forwarding of requests to Router over TLS

| If you want to: | Encrypt communication between HAProxy and the Gorouter |
|-------------------------------|---|
| Then configure the following: | <ol style="list-style-type: none"> 1. Leave Enable selected. 2. In the Certificate Authority for HAProxy Backend field, specify the Certificate Authority (CA) that signed the certificate you configured in the Certificate and Private Key for HAProxy and Router field. <div>  Note: If you used the Generate RSA Certificate link to generate a self-signed certificate, then the CA to specify is the Ops Manager CA, which you can locate at the <code>/api/v0/certificate_authorities</code> endpoint in the Ops Manager API. </div> <ol style="list-style-type: none"> 3. Make sure that Gorouter and HAProxy have TLS cipher suites in common in the TLS Cipher Suites for Router and TLS Cipher Suites for HAProxy fields. |
| See also: | <ul style="list-style-type: none"> ◦ Terminating SSL/TLS at the Load Balancer and Gorouter ◦ Providing a Certificate for Your SSL/TLS Termination Point ◦ Using the Ops Manager API |

◦ Disable HAProxy forwarding of requests to Router over TLS

| If you want to: | Use non-encrypted communication between HAProxy and Gorouter, or you are not using HAProxy |
|-------------------------------|---|
| Then configure the following: | <ol style="list-style-type: none"> 1. Select Disable. 2. If you are not using HAProxy, set the number of HAProxy job instances to <code>0</code> on the Resource Config page. See Disable Unused Resources. |
| See also: | <ul style="list-style-type: none"> ◦ Terminating SSL/TLS at the Gorouter Only ◦ Terminating SSL/TLS at the Load Balancer Only |

13. If you are not using SSL encryption or if you are using self-signed certificates, select **Disable SSL certificate verification for this environment**. Selecting this checkbox also disables SSL verification for route services.

 **Note:** For production deployments, Pivotal does not recommend disabling SSL certificate verification.

14. (Optional) If you want HAProxy or the Gorouter to reject any HTTP (non-encrypted) traffic, select the **Disable HTTP on HAProxy and Gorouter** checkbox. When selected, HAProxy and Gorouter will not listen on port 80.

☐ Disable HTTP on HAProxy and Gorouter

15. (Optional) Select the **Disable insecure cookies on the Router** checkbox to set the secure flag for cookies generated by the router.
16. (Optional) To disable the addition of Zipkin tracing headers on the Gorouter, deselect the **Enable Zipkin tracing headers on the router** checkbox. Zipkin tracing headers are enabled by default. For more information about using Zipkin trace logging headers, see [Zipkin Tracing in HTTP Headers](#).
17. (Optional) To stop the Router from writing access logs to local disk, deselect the **Enable Router to write access logs locally** checkbox. You should consider disabling this checkbox for high traffic deployments since logs may not be rotated fast enough and can fill up the disk.
18. By default, the PAS routers handle traffic for applications deployed to an isolation segment created by the PCF Isolation Segment tile. To configure the PAS routers to reject requests for applications within isolation segments, select the **Routers reject requests for Isolation Segments** checkbox.

☐ Routers reject requests for Isolation Segments

Do not enable this option without deploying

routers for each isolation segment. See the following topics for more information:

- [Installing PCF Isolation Segment](#)
- [Sharding Routers for Isolation Segments](#)

19. In the **Choose whether to enable route services** section, choose either **Enable route services** or **Disable route services**. Route services are a class of [marketplace services](#) that perform filtering or content transformation on application requests and responses. See the [Route Services](#) topic for details.
 - a. If you enabled route services, you can also configure the **Bypass security checks for route service lookup** field. Pivotal recommends that you do not enable this field because it has potential security concerns. However, you may need to enable it if your load balancer requires mutual TLS from clients. For more information, see [Configuring Route Service Lookup](#).
20. (Optional) If you want to limit the number of app connections to the backend, enter a value in the **Max Connections Per Backend** field. You can use this field to prevent a poorly behaving app from all the connections and impacting other apps.

To choose a value for this field, review the peak concurrent connections received by instances of the most popular apps in your deployment. You can determine the number of concurrent connections for an app from the `httpStartStop` event metrics emitted for each app request.

If your deployment uses PCF Metrics, you can also obtain this peak concurrent connection information from [Network Metrics](#). The default value is

Max Connections Per Backend *

0

500

21. Under **Enable Keepalive Connections for Router**, select **Enable** or **Disable**. Keepalive connections are enabled by default. For more information, see [Keepalive Connections](#) in *HTTP Routing*.

Enable Keepalive Connections for Router *

- ☒ Enable
- ☐ Disable

22. (Optional) Increase the number of seconds in the **Router Timeout to Backends** field to accommodate larger uploads over connections with high latency. Set this value to less than or equal to the idle timeout value of the Azure load balancer, which defaults to 4 minutes.

Note: If the router timeout value exceeds the Azure LB timeout, you may experience intermittent TCP resets. For more information about configuring Azure load balancer idle timeout, see the [Azure documentation](#).

23. (Optional) Use the **Frontend Idle Timeout for Gorouter and HAProxy** field to help prevent connections from your load balancer to Gorouter or HAProxy from being closed prematurely. The value you enter sets the duration, in seconds, that Gorouter or HAProxy maintains an idle open connection from a load balancer that supports keep-alive.

In general, set the value higher than your load balancer's backend idle timeout to avoid the race condition where the load balancer sends a request before it discovers that Gorouter or HAProxy has closed the connection.

See the following table for specific guidance and exceptions to this rule:

| IaaS | Guidance |
|-------|---|
| AWS | AWS ELB has a default timeout of 60 seconds, so Pivotal recommends a value greater than <code>60</code> . |
| Azure | By default, Azure load balancer times out at 240 seconds without sending a TCP RST to clients, so as an exception, Pivotal recommends a value lower than <code>240</code> to force the load balancer to send the TCP RST. |
| GCP | GCP has a default timeout of 600 seconds. For GCP HTTP load balancers, Pivotal recommends a value greater than <code>600</code> . For GCP TCP load balancers, Pivotal recommends a value less than <code>600</code> to force the load balancer to send a TCP RST. |
| Other | Set the timeout value to be greater than that of the load balancer's backend idle timeout. |

 **Note:** Do not set a frontend idle timeout lower than six seconds.

24. (Optional) Increase the value of **Load Balancer Unhealthy Threshold** to specify the amount of time, in seconds, that the router continues to accept connections before shutting down. During this period, healthchecks may report the router as unhealthy, which causes load balancers to failover to other routers. Set this value to an amount greater than or equal to the maximum time it takes your load balancer to consider a router instance unhealthy, given contiguous failed healthchecks.
25. (Optional) Modify the value of **Load Balancer Healthy Threshold**. This field specifies the amount of time, in seconds, to wait until declaring the Router instance started. This allows an external load balancer time to register the Router instance as healthy.

Load Balancer Unhealthy Threshold *

Load Balancer Healthy Threshold *

26. (Optional) If app developers in your organization want certain HTTP headers to appear in their app logs with information from the Gorouter, specify them in the **HTTP Headers to Log** field. For example, to support app developers that deploy Spring apps to PCF, you can enter [Spring-specific HTTP headers](#).

HTTP Headers to Log

27. If you expect requests larger than the default maximum of 16 Kbytes, enter a new value (in bytes) for **HAProxy Request Max Buffer Size**. You may need to do this, for example, to support apps that embed a large cookie or query string values in headers.

28. If your PCF deployment uses HAProxy and you want it to receive traffic only from specific sources, use the following fields:

- **HAProxy Protected Domains:** Enter a comma-separated list of domains to protect from unknown source requests.
- **HAProxy Trusted CIDRs:** Optionally, enter a space-separated list of CIDRs to limit which IP addresses from the **Protected Domains** can send traffic to PCF.

HAProxy Protected Domains

A comma-separated list of domains to protect from requests from unknown sources. Use this property in conjunction with "Trusted CIDRs" to protect these domains from requests from unknown sources.

HAProxy Trusted CIDRs

29. The **Loggregator Port** defaults to `443` if left blank. Leave this field blank.

Container Network Interface Plugin *

 Silk

30. For **Container Network Interface Plugin**, ensure **Silk** is selected and review the following fields:

 **Note:** The **External** option exists to support NSX-T integration for vSphere deployments.

- a. (Optional) You can change the value in the **Applications Network Maximum Transmission Unit (MTU)** field. Pivotal recommends setting the MTU value for your application network to `1454`. Some configurations, such as networks that use GRE tunnels, may require a smaller MTU value.
- b. (Optional) Enter an IP range for the overlay network in the **Overlay Subnet** box. If you do not set a custom range, Ops Manager uses `10.255.0.0/16`.

 **warning:** The overlay network IP range must not conflict with any other IP addresses in your network.

- c. Enter a UDP port number in the **VXLAN Tunnel Endpoint Port** box. If you do not set a custom port, Ops Manager uses 4789.
- d. For **Denied logging interval**, set the per-second rate limit for packets blocked by either a container-specific [networking policy](#) or by [Application Security Group](#) rules applied across the space, org, or deployment. This field defaults to `1`.
- e. For **UDP logging interval**, set the per-second rate limit for UDP packets sent and received. This field defaults to `100`.
- f. To enable logging for app traffic, select **Log traffic for all accepted/denied application packets**. See [Manage Logging for Container-to-Container Networking](#) for more information.
- g. By default, containers use the same DNS servers as the host. If you want to override the DNS servers to be used in containers, enter a comma-separated list of servers in **DNS Servers**.

 **Note:** If your deployment uses BOSH DNS, which is the default, you cannot use this field to override the DNS servers used in containers.

- h. For **Database Connection Timeout**, set the connection timeout for clients of the policy server and silk databases. The default value is `120`. You may need to increase this value if your deployment experiences timeout issues related to Container-to-Container Networking.

31. For **DNS Search Domains**, enter DNS search domains for your containers as a comma-separated list. DNS on your containers appends these names to its host names, to resolve them into full domain names.

DNS Search Domains

DNS search domains to be used in containers. A comma-separated list can be specified.

32. For **Database Connection Timeout**, set the connection timeout for clients of the policy server and silk databases. The default value is `120`. You may need to increase this value if your deployment experiences timeout issues related to Container-to-Container Networking.

33. (Optional) TCP Routing is disabled by default. You should enable this feature if your DNS sends TCP traffic through a load balancer rather than directly to a TCP router. To enable TCP routing:

- a. Select **Enable TCP Routing**.
- b. For **TCP Routing Ports**, enter a single port or a range of ports for the load balancer to forward to. These are the same ports that you configured in the [Pre-Deployment Steps](#) of the *Enabling TCP Routing* topic.

- To support multiple TCP routes, Pivotal recommends allocating multiple ports.
- To allocate a list of ports rather than a range:

1. Enter a single port in the **TCP Routing Ports** field.
2. After deploying PAS, follow the directions in [Configuring a List of TCP Routing Ports](#) to add TCP routing ports using the cf CLI.

Enable TCP requests to your apps via specific ports on the TCP router. You will want to configure a load balancer to forward these TCP requests to the TCP routers. If you do not have a load balancer, then you can also send traffic directly to the TCP router.*

☐ Select this option if you prefer to enable TCP Routing at a later time
 ☒ **Enable TCP Routing**

TCP Routing Ports (one-time configuration, if you want to update this value you can via the CF CLI) *

- c. For Azure, you also need to specify the name of Azure load balancer in the LOAD BALANCER column of TCP Router job of the **Resource Config** screen. You configure this later on in PAS. See [Configuring Resources](#).

34. (Optional) To disable TCP routing, click **Select this option if you prefer to enable TCP Routing at a later time** For more information, see the [Configuring TCP Routing in PAS](#) topic.

35. Click **Save**.

Step 5: Configure Application Containers

1. Select **Application Containers**.

Enable microservice frameworks, private Docker registries, and other services that support your applications at a container level.

- ☒ Enable Custom Buildpacks
- ☒ Allow SSH access to app containers
- ☒ Enable SSH when an app is created
- ☒ Enable the GrootFS container image plugin for Garden RunC
- ☐ Router uses TLS to verify application identity

Private Docker Insecure Registry Whitelist

Docker Images Disk-Cleanup Scheduling on Cell VMs*

- ☐ Never clean up Cell disk-space
- ☐ Routinely clean up Cell disk-space
- ☒ Clean up disk-space once threshold is reached

Threshold of Disk-Used (MB) (min: 1) *

- The **Enable Custom Buildpacks** checkbox governs the ability to pass a custom buildpack URL to the `-b` option of the `cf push` command. By default, this ability is enabled, letting developers use custom buildpacks when deploying apps. Disable this option by disabling the checkbox. For more information about custom buildpacks, refer to the [buildpacks](#) section of the PCF documentation.
- The **Allow SSH access to app containers** checkbox controls SSH access to application instances. Enable the checkbox to permit SSH access across your deployment, and disable it to prevent all SSH access. See the [Application SSH Overview](#) topic for information about SSH access permissions at the space and app scope.
- If you want to enable SSH access for new apps by default in spaces that allow SSH, select **Enable SSH when an app is created**. If you deselect the checkbox, developers can still enable SSH after pushing their apps by running `cf enable-ssh APP-NAME`.
- If you want to disable the Garden Root filesystem (GrootFS), deselect the **Enable the GrootFS container image plugin for Garden RunC** checkbox. Pivotal recommends using this plugin, so it is enabled by default. However, some external components are sensitive to dependencies with filesystems such as GrootFS. If you experience issues, such as antivirus or firewall compatibility problems, deselect the checkbox to roll back to the plugin that is built into Garden RunC. For more information about GrootFS, see [Component: Garden](#) and [Container Mechanics](#).

 **Note:** If you modify this setting, Pivotal recommends recreating all VMs in the BOSH Director config. You can do this by selecting the **Recreate all VMs** checkbox in the **Director Config** pane of the BOSH Director tile before you redeploy.

- To enable Gorouter to verify app identity using TLS, select the **Router uses TLS to verify application identity** checkbox.

Verifying app identity using TLS enables encryption between router and app containers and guards against misrouting during control plane failures. For more information about Gorouter route consistency modes, see [Preventing Misrouting](#) in *HTTP Routing*.

 **warning:** TLS routing requires an additional 32 MB of RAM capacity on Diego cells per app instance. It also requires additional CPU capacity on Diego cells. If the total amount of Diego cell memory available is less than 32 MB times the number of running app instances, scale your Diego cells before configuring the Gorouter with TLS.

Warning: You may see an increase of memory and CPU usage for your Gorouters after enabling TLS routing. If the total amount of memory and CPU usage of the Gorouters in your environment are close to the size limit, scale your Gorouters before enabling TLS routing.

- You can configure Pivotal Application Service (PAS) to run app instances in Docker containers by supplying their IP address ranges in the **Private Docker Insecure Registry Whitelist** textbox. See the [Using Docker Registries](#) topic for more information.
- Select your preference for **Docker Images Disk-Cleanup Scheduling on Cell VMs**. If you choose **Clean up disk-space once threshold is reached**, enter a **Threshold of Disk-Used** in megabytes. For more information about the configuration options and how to configure a threshold, see [Configuring Docker Images Disk-Cleanup Scheduling](#).
- Enter a number in the **Max Inflight Container Starts** textbox. This number configures the maximum number of started instances across the Diego cells in your deployment. For more information about this feature, see [Setting a Maximum Number of Started Containers](#).
- Under **Enabling NFSv3 volume services**, select **Enable** or **Disable**. NFS volume services allow application developers to bind existing NFS volumes to their applications for shared file access. For more information, see the [Enabling NFS Volume Services](#) topic.

Note: In a clean install, NFSv3 volume services is enabled by default. In an upgrade, NFSv3 volume services is set to the same setting as it was in the previous deployment.

- (Optional) To configure LDAP for NFSv3 volume services, do the following:

Enabling NFSv3 volume services will allow application developers to bind existing NFS volumes to their applications for shared file access. *

☒ Enable

LDAP Service Account User

LDAP Service Account Password

LDAP Server Host

LDAP Server Port

LDAP User Fully-Qualified Domain Name

☐ Disable

Format of timestamps in Diego logs *

☒ RFC3339 timestamps (e.g. 2018-02-09T00:54:13.479724884Z)

☐ Seconds since the Unix epoch (e.g. 1518137653.479724884)

Save

- For **LDAP Service Account User**, enter the username of the service account in LDAP that will manage volume services.
- For **LDAP Service Account Password**, enter the password for the service account.
- For **LDAP Server Host**, enter the hostname or IP address of the LDAP server.
- For **LDAP Server Port**, enter the LDAP server port number. If you do not specify a port number, Ops Manager uses 389.
- For **LDAP User Fully-Qualified Domain Name**, enter the fully qualified path to the LDAP service account. For example, if you have a service account named `volume-services` that belongs to organizational units (OU) named `service-accounts` and `my-company`, and your domain is named `domain`, the fully qualified path looks like the following:

```
CN=volume-services,OU=service-accounts,OU=my-company,DC=domain,DC=com
```

12. By default, PAS manages container images using the [GrootFS](#) plugin for Garden-runC. If you experience issues with GrootFS, you can disable the plugin and use the image plugin built into Garden-runC.
13. Select the **Format of timestamps in Diego logs**, either **RFC3339 timestamps** or **Seconds since the Unix epoch**. Fresh PAS v2.2 installations default to **RFC3339 timestamps**, while upgrades to PAS v2.2 from previous versions default to **Seconds since the Unix epoch**.
14. You can optionally modify the **Default health check timeout**. The value configured for this field is the amount of time allowed to elapse between starting up an app and the first healthy response from the app. If the health check does not receive a healthy response within the configured timeout, then the app is declared unhealthy. The default timeout is seconds and the maximum configurable timeout is seconds.
15. Click **Save**.

Step 6: Configure Application Developer Controls

1. Select **Application Developer Controls**.

Configure restrictions and default settings for applications pushed to Application Service.

Maximum File Upload Size (MB) (min: 1024, max: 2048) *

Default App Memory (MB) (min: 64, max: 2048) *

Default App Memory Quota per Org (MB) (min: 10240, max: 102400) *

Maximum Disk Quota per App (MB) (min: 512, max: 20480) *

Default Disk Quota per App (MB) (min: 512, max: 20480) *

Default Service Instances Quota per Org (min: 0, max: 1000) *

Staging Timeout (Seconds) *

☐ Allow Space Developers to manage network policies

☒ Enable Service Discovery for Apps

Save

2. Enter the **Maximum File Upload Size (MB)**. This is the maximum size of an application upload.
3. Enter the **Default App Memory (MB)**. This is the amount of RAM allocated by default to a newly pushed application if no value is specified with the cf CLI.

4. Enter the **Default App Memory Quota per Org**. This is the default memory limit for all applications in an org. The specified limit only applies to the first installation of PAS. After the initial installation, operators can use the cf CLI to change the default value.
5. Enter the **Maximum Disk Quota per App (MB)**. This is the maximum amount of disk allowed per application.

 **Note:** If you allow developers to push large applications, PAS may have trouble placing them on Cells. Additionally, in the event of a system upgrade or an outage that causes a rolling deploy, larger applications may not successfully re-deploy if there is insufficient disk capacity. Monitor your deployment to ensure your Cells have sufficient disk to run your applications.

6. Enter the **Default Disk Quota per App (MB)**. This is the amount of disk allocated by default to a newly pushed application if no value is specified with the cf CLI.
7. Enter the **Default Service Instances Quota per Org**. The specified limit only applies to the first installation of PAS. After the initial installation, operators can use the cf CLI to change the default value .
8. Enter the **Staging Timeout (Seconds)**. When you stage an application droplet with the Cloud Controller, the server times out after the number of seconds you specify in this field.
9. Select the **Allow Space Developers to manage network policies** checkbox to permit developers to manage their own network policies for their applications.
10. The **Enable Service Discovery for Apps** checkbox, which enables service discovery between applications, is enabled by default. To disable this feature, clear this checkbox. For more information about application service discovery, see the [App Service Discovery](#) section of the *Understanding Container-to-Container Networking* topic.
11. Click **Save**.

Step 7: Review Application Security Group

Setting appropriate [Application Security Groups](#) is critical for a secure deployment. Type ☐ in the box to acknowledge that once the Pivotal Application Service (PAS) deployment completes, you will review and set the appropriate application security groups. See [Restricting App Access to Internal PCF Components](#) for instructions.

Setting appropriate Application Security Groups that control application network policy is the responsibility of the Elastic Runtime administration team. Please refer to the Application Security Groups topic in the Pivotal Cloud Foundry documentation for more detail on completing this activity after the Elastic Runtime deployment completes.

Type X to acknowledge that you understand this message *

Save

Step 8: Configure UAA

1. Select **UAA**.
2. (Optional) Under **JWT Issuer URI**, enter the URI that UAA uses as the issuer when generating tokens.

JWT Issuer URI

- Under **SAML Service Provider Credentials**, enter a certificate and private key to be used by UAA as a SAML Service Provider for signing outgoing SAML authentication requests. You can provide an existing certificate and private key from your trusted Certificate Authority or generate a self-signed certificate. The following domain must be associated with the certificate: `*.login.YOUR-SYSTEM-DOMAIN`.

Note: The Pivotal Single Sign-On Service and Pivotal Spring Cloud Services tiles require the `*.login.YOUR-SYSTEM-DOMAIN`.

- If the private key specified under **Service Provider Credentials** is password-protected, enter the password under **SAML Service Provider Key**

SAML Service Provider Credentials *

-----BEGIN CERTIFICATE-----
M
U
H
M
-----END CERTIFICATE-----

-----BEGIN PRIVATE KEY-----
-----END PRIVATE KEY-----

[Change](#)

SAML Service Provider Key Password

Secret

Password.

- (Optional) To override the default value, enter a custom SAML Entity ID in the **SAML Entity ID Override** field. By default, the SAML Entity ID is `http://login.YOUR-SYSTEM-DOMAIN` where `YOUR-SYSTEM-DOMAIN` is set in the **Domains > System Domain** field.
- For **Signature Algorithm**, choose an algorithm from the dropdown menu to use for signed requests and assertions. The default value is `SHA256`.
- (Optional) In the **Apps Manager Access Token Lifetime**, **Apps Manager Refresh Token Lifetime**, **Cloud Foundry CLI Access Token Lifetime**, and **Cloud Foundry CLI Refresh Token Lifetime** fields, change the lifetimes of tokens granted for Apps Manager and Cloud Foundry Command Line Interface (cf CLI) login access and refresh. Most deployments use the defaults.

Apps Manager Access Token Lifetime (in seconds) *

Apps Manager Refresh Token Lifetime (in seconds) *

Cloud Foundry CLI Access Token Lifetime (in seconds) *

Cloud Foundry CLI Refresh Token Lifetime (in seconds) *

Global Login Session Max Timeout (in seconds) *

Global Login Session Idle Timeout (in seconds) *

Customize Username Label (on login page) *

Customize Password Label (on login page) *

Proxy IPs Regular Expression *

8. (Optional) In the **Global Login Session Max Timeout** and **Global Login Session Idle Timeout** fields, change the maximum number of seconds before a global login times out. These fields apply to the following:
 - **Default zone sessions:** Sessions in Apps Manager, PCF Metrics, and other web UIs that use the UAA default zones
 - **Identity zone sessions:** Sessions in apps that use a UAA identity zone, such as a Single Sign-On service plan
9. (Optional) Customize the text prompts used for username and password from the cf CLI and Apps Manager login popup by entering values for **Customize Username Label (on login page)** and **Customize Password Label (on login page)**.
10. (Optional) The **Proxy IPs Regular Expression** field contains a pipe-delimited set of regular expressions that UAA considers to be reverse proxy IP addresses. UAA respects the `x-forwarded-for` and `x-forwarded-proto` headers coming from IP addresses that match these regular expressions. To configure UAA to respond properly to Gorouter or HAProxy requests coming from a public IP address, append a regular expression or regular expressions to match the public IP address.
11. You can configure UAA to use an internal MySQL database provided with PCF, or you can configure an external database provider. Follow the procedures in either the [Internal Database Configuration](#) or the [External Database Configuration](#) section below.

 **Note:** If you are performing an upgrade, do not modify your existing internal database configuration or you may lose data. You must migrate your existing data before changing the configuration. See [Upgrading Pivotal Cloud Foundry](#) for additional upgrade information, and contact [Pivotal Support](#) for help.

Internal Database Configuration

When you configure the UAA to use an internal MySQL database, it uses the type of database selected in the **Databases** pane. See the [Configure Internal Databases](#) section for details.

1. Select **Internal MySQL**.

Choose the location of your UAA database *

☒ Internal MySQL (preferred for complete high-availability)
☐ External (preferred if, for example, you use AWS RDS)

 **Note:** If you configure your system databases as external in the **Databases** pane, selecting Internal MySQL in the **UAA** pane has no effect.

2. Click **Save**.
3. Ensure that you complete the [Configure Internal MySQL](#) step later in this topic to configure high availability for your internal MySQL databases.

External Database Configuration

1. From the **UAA** section in Pivotal Application Service (PAS), select **External**.

Choose the location of your UAA database *

☐ Internal MySQL (preferred for complete high-availability)
☒ External (preferred if, for example, you use AWS RDS)

Hostname *

TCP Port *

Username *

Password *

Secret

2. For **Hostname**, enter the hostname of the database server.
3. For **TCP Port**, enter the port of the database server.
4. For **User Account and Authentication database username**, specify a unique username that can access this specific database on the database server.
5. For **User Account and Authentication database password**, specify a password for the provided username.
6. Click **Save**.

Step 9: Configure CredHub

 **Note:** Enabling CredHub is not required. However, you cannot leave the fields under **Encryption Keys** blank. If you do not intend to use CredHub, enter any text in the **Name** and **Key** fields as placeholder values.

1. Select **CredHub**.
2. Choose the location of your CredHub database. PAS includes this CredHub database for services to store their service instance credentials.

 **Note:** You cannot choose **Internal** for the CredHub database if you choose **External** for your System Databases. See [Configure System](#)

Databases below.

Configure the CredHub Server

Choose the location of your CredHub database *

- ☒ Internal MySQL (preferred for complete high-availability)
- ☐ External (preferred if, for example, you use Google Cloud SQL)

If you chose **External**, enter the following:

- **Hostname.** This is the IP address of your database server.
- **TCP Port.** This is the port of your database server, such as `3306`.
- **Username.** This is a unique username that can access your CredHub database on the database server.
- **Password.** This is the password for the provided username.
- **Database CA Certificate.** This certificate is used when encrypting traffic to and from the database.

3. Under **Encryption Keys**, specify one or more keys to use for encrypting and decrypting the values stored in the CredHub database.

Encryption Keys

Name *

Name of the encryption key.

Provider*

Key *

☐ Primary

- **Name.** This is the name of the encryption key.
 - If you plan to use internal encryption, enter any key name.
 - If you plan to use an HSM as your encryption provider, enter a key name that already exists on your HSM or a new key name. For each new key name, CredHub generates a key in **HSM Provider Partition** that you configure below.
- **Provider.** This is the provider of the encryption key. If you plan to configure an HSM provider and HSM servers below, select **HSM**. Otherwise, select **Internal**.
- **Key.** If you select internal encryption, this key is used for encrypting all data. The key must be at least 20 characters long.
 - If you selected **Internal** above, enter a randomly generated value under **Key**.
 - If you selected **HSM** above, enter a placeholder value under **Key**. CredHub does not use this key for encryption. However, you cannot leave the **Key** field blank.
- **Primary.** This checkbox is used for marking the key you specified above as the primary encryption key. You must mark one key as **Primary**. Do not mark more than one key as **Primary**.

Note: For information about using additional keys for key rotation, see the [Rotating Runtime CredHub Encryption Keys](#) topic.

4. (Optional) To configure CredHub to use an HSM, complete the following fields:

- **HSM Provider Partition.** This is the name of the HSM provider partition.
- **HSM Provider Partition Password.** This password is used to access the HSM provider partition.
- **HSM Provider Client Certificate.** This is the client certificate for the HSM. For more information, see [Create and Register HSM Clients](#) in the

Preparing CredHub HSMs for Configuration topic.

- In the **HSM Provider Servers** section, click **Add** to add an HSM server. You can add multiple HSM servers. For each HSM server, complete the following fields:
 - **Host Address.** This is the host name or IP address of the HSM server.
 - **Port.** This is the port of the HSM server. If you do not know your port address, enter `1792`.
 - **Partition Serial Number.** This is the serial number of the HSM partition.
 - **HSM Certificate.** This is the certificate for the HSM server. The HSM presents this certificate to CredHub to establish a two-way TLS connection.

5. If your deployment uses any PCF services that support storing service instance credentials in CredHub and you want to enable this feature, select the **Secure Service Instance Credentials** checkbox.

6. Click **Save**.

7. Select the **Resource Config** pane.

8. Under the **Job** column of the **CredHub** row, set the number of instances to `2`. This is the minimum instance count required for high availability.

9. Click **Save**.

For more information about using CredHub for securing service instance credentials, see [Securing Service Instance Credentials with Runtime CredHub](#).

Step 10: Configure Authentication and Enterprise SSO

1. Select **Authentication and Enterprise SSO**.

Configure your user store access, which can be an internal user store (managed by Cloud Foundry's UAA) or an external user store (LDAP or SAML). You can also adjust the lifetimes of authentication tokens.

Configure your UAA user account store with either internal or external authentication mechanisms *

☒ Internal UAA (provided by Elastic Runtime; configure your password policy below)

Minimum Password Length *

Minimum Uppercase Characters Required for Password *

Minimum Lowercase Characters Required for Password *

Minimum Numerical Digits Required for Password *

Minimum Special Characters Required for Password *

Maximum Password Entry Attempts Allowed *

2. To authenticate user sign-ons, your deployment can use one of three types of user database: the UAA server's internal user store, an external SAML identity provider, or an external LDAP server.

- To use the internal UAA, select the **Internal** option and follow the instructions in the [Configuring UAA Password Policy](#) topic to configure your password policy.
- To connect to an external identity provider through SAML, scroll down to select the **SAML Identity Provider** option and follow the instructions in the [Configuring PCF for SAML](#) section of the *Configuring Authentication and Enterprise SSO for Pivotal Application Service (PAS)* topic.
- To connect to an external LDAP server, scroll down to select the **LDAP Server** option and follow the instructions in the [Configuring LDAP](#) section of the *Configuring Authentication and Enterprise SSO for PAS* topic.

3. Click **Save**.

Step 11: Configure System Databases

You can configure PAS to use an internal MySQL database provided with PCF, or you can configure an external database provider for the databases required by PAS.

 **Note:** If you are performing an upgrade, do not modify your existing internal database configuration or you may lose data. You must migrate your existing data first before changing the configuration. Contact Pivotal Support for help. See [Upgrading Pivotal Cloud Foundry](#) for additional upgrade information.

Internal Database Configuration

If you want to use internal databases for your deployment, perform the following steps:

1. Select **Databases**.

2. Select one of the **Internal Databases** options:

- Internal Databases - MySQL - Percona XtraDB Cluster uses [Percona Server](#) with TLS encryption between server cluster nodes.
- Internal Databases - MySQL - MariaDB Galera Cluster uses [MariaDB](#) with cluster nodes communicating over plaintext.

⚠ warning: Changing existing internal databases from **MySQL - MariaDB Galera Cluster** to **MySQL - Percona XtraDB Cluster** migrates the databases after you click **Apply Changes**, causing temporary system downtime. See [Migrate to Internal Percona MySQL](#) for details.

Choose the location of your system databases. Please consult the documentation for migrating existing installations from MariaDB to Percona. *

- ☒ Internal Databases - MySQL - Percona XtraDB Cluster
- ☐ Internal Databases - MySQL - MariaDB Galera Cluster (deprecated - planned to be removed in PAS 2.4)
- ☐ External Databases - (e.g. AWS RDS)

Save

3. Click **Save**.

Then proceed to [Step 12: \(Optional\) Configure Internal MySQL](#) to configure high availability and automatic backups for your internal MySQL databases.

External Database Configuration

⚠ warning: Protect whichever database you use in your deployment with a password.

To create your Pivotal Application Service (PAS) databases, follow the procedure below.

💡 Note: Exact configurations depend on your database provider. The following procedure uses AWS RDS as an example.

- Add the `ubuntu` account key pair from your IaaS deployment to your local SSH profile so you can access the Ops Manager VM. For example, in AWS, you add a key pair created in AWS:

```
$ ssh-add aws-keypair.pem
```

- SSH in to your Ops Manager using the Ops Manager FQDN and the username `ubuntu`:

```
$ ssh ubuntu@OPS-MANAGER-FQDN
```

- Log in to your MySQL database instance using the appropriate hostname and user login values configured in your IaaS account. For example, to log in to your AWS RDS instance, run the following MySQL command:

```
$ mysql --host=RDSHOSTNAME --user=RDSUSERNAME --password=RDSPASSWORD
```

- Run the following MySQL commands to create databases for the PAS components that require a relational database:

```
CREATE database ccd;
CREATE database notifications;
CREATE database autoscale;
CREATE database app_usage_service;
CREATE database routing;
CREATE database diego;
CREATE database account;
CREATE database nfsvolume;
CREATE database networkpolicyserver;
CREATE database silk;
CREATE database locket;
CREATE database uaa;
CREATE database credhub;
```

💡 Note: The command `CREATE database credhub;` is optional if you have no CredHub instances. By default, CredHub has `0` instances.

5. Type `exit` to quit the MySQL client, and `exit` again to close your connection to the Ops Manager VM.
6. In PAS, select **Databases**.
7. Select the **External Databases** option.

 **Note:** If you configure databases as external, you cannot configure an internal database in the **UAA** pane.

8. For **Hostname**, enter the hostname of the database server.
9. For **TCP Port**, enter the port of the database server.
10. Each component that requires a relational database has two corresponding fields: one for the database username and one for the database password. For each set of fields, specify a unique username that can access this specific database on the database server and a password for the provided username.

 **Note:** Ensure that the networkpolicyserver database user has the `ALL PRIVILEGES` permission.

11. Click **Save**.

Step 12: (Optional) Configure Internal MySQL

 **Note:** You only need to configure this section if you have selected one of the **Internal Databases - MySQL** options in the **Databases** section.

To use internal MySQL in High Availability configuration, you define a load balancer rule that lets PAS components send queries a single hostname backed by two redundant proxies. Each proxy then directs query traffic to three MySQL server nodes.

1. Allocate an internal load balancer rule to balance traffic between two static IP addresses. The static IP addresses cannot be within the range that that you have reserved for PAS.
The load balancer rule is separate from the software provided by Pivotal, and you need to define it within your infrastructure.
 - **Make your idle time out long enough to not interrupt long-running queries.** When queries take a long time, the load balancer can time out and interrupt the query.
For example, [AWS's Elastic Load Balancer](#) has a default idle timeout of 60 seconds, so queries that take longer than this duration sever the MySQL connection and return an error.
 - **Configure a healthcheck or monitor, using TCP against port 1936.** This defaults to TCP port `1936`, to maintain backwards compatibility with previous releases. This port is not configurable. Unauthenticated healthchecks against port 3306 may cause the service to become unavailable and require manual intervention to fix.
 - **Configure the load balancer to route traffic for TCP port 3306 to the IPs of all proxy instances on TCP port 3306.**
 - Record the hostname of the load balancer rule and the two static IP addresses.

 **warning:** You must configure a load balancer to achieve complete high availability.

2. From the PAS tile in Ops Manager, Select **Internal MySQL**.
3. In the **MySQL Proxy IPs** field, enter the static IP addresses used by the internal MySQL load balancer rule.

Only configure this section if you selected Internal Databases - MySQL in the previous Databases section.

A proxy tier routes MySQL connections from internal components to healthy cluster nodes. Configure DNS and/or your own load balancer to point to multiple proxy instances for increased availability. TCP healthchecks can be configured against port 1936.

The automated backups functionality works with any S3-compatible file store that can receive your backup files.

MySQL Proxy IPs

MySQL Service Hostname

4. For **MySQL Service Hostname**, enter the IP address or hostname for your load balancer. If you leave this field blank, components are configured with the IP address of the first proxy instance entered above.
5. In the **Replication canary time period** field, leave the default of 30 seconds or modify the value based on the needs of your deployment. Lower numbers cause the canary to run more frequently, which means that the canary reacts more quickly to replication failure but adds load to the database.
6. In the **Replication canary read delay** field, leave the default of 20 seconds or modify the value based on the needs of your deployment. This field configures how long the canary waits, in seconds, before verifying that data is replicating across each MySQL node. Clusters under heavy load can experience a small replication lag as write-sets are committed across the nodes.
7. (**Required**): In the **E-mail address** field, enter the email address where the MySQL service sends alerts when the cluster experiences a replication issue or when a node is not allowed to auto-rejoin the cluster.
8. To prohibit the creation of command line history files on the MySQL nodes, disable the **Allow Command History** checkbox.
9. To allow the admin and roadmin to connect from any remote host, enable the **Allow Remote Admin Access** checkbox. When the checkbox is disabled, admins must `bosh ssh` into each MySQL VM to connect as the MySQL super user.

 **Note:** Network configuration and Application Security Groups restrictions may still limit a client's ability to establish a connection with the databases.

10. For **Cluster Probe Timeout**, enter the maximum amount of time, in seconds, that a new node will search for existing cluster nodes. If left blank, the default value is 10 seconds.

Replication canary time period *

30

Replication canary read delay *

20

E-mail address (required) *

Fill in your desired email address

☒ Allow Command History

Cluster Probe Timeout

11. For **Max Connections**, enter the maximum number of connections allowed to the database. If left blank, the default value is 1500.
12. If you want to log audit events for internal MySQL, select **Enable server activity logging** under **Server Activity Logging**.
 - a. For the **Event types** field, you can enter the events you want the MySQL service to log. By default, this field includes `connect` and `query`, which tracks who connects to the system and what queries are processed.

13. Enter values for the following fields:
 - **Load Balancer Healthy Threshold:** Specifies the amount of time, in seconds, to wait until declaring the MySQL Proxy instance started. This allows an external load balancer time to register the instance as healthy.
 - **Load Balancer Unhealthy Threshold:** Specifies the amount of time, in seconds, that the MySQL Proxy continues to accept connections before shutting down. During this period, the Healthcheck reports as unhealthy to cause load balancers to fail over to other proxies. You must enter a value greater than or equal to the maximum time it takes your load balancer to consider a proxy instance unhealthy, given repeated failed healthchecks.
14. If you want to enable the MySQL interruptor feature, select the checkbox to **Prevent node auto re-join**. This feature stops all writes to the MySQL database if it notices an inconsistency in the dataset between the nodes. For more information, see the [Interruptor](#) section in the MySQL for PCF documentation.
15. Click **Save**.

For more information on how to monitor the node health of your MySQL Proxy instances, see [Using the MySQL Proxy](#).

Step 13: Configure File Storage

To minimize system downtime, Pivotal recommends using highly resilient and redundant *external* filestores for your Pivotal Application Service (PAS) file storage.

When configuring file storage for the Cloud Controller in PAS, you can select one of the following:

- Internal WebDAV filestore
- External S3-compatible or Ceph-compatible filestore
- External Google Cloud Storage with Access Key and Secret Key
- External Google Cloud Storage with Service Account
- External Azure Cloud Storage

For production-level PCF deployments on Azure, the recommended selection is Azure Storage. For more information about production-level PCF deployments on Azure, see the [Reference Architecture for Pivotal Cloud Foundry on Azure](#).

For more factors to consider when selecting file storage, see [Considerations for Selecting File Storage in Pivotal Cloud Foundry](#).

Internal Filestore

Internal file storage is only appropriate for small, non-production deployments.

To use the PCF internal filestore, perform the following steps:

1. In the Pivotal Application Service (PAS) tile, select **File Storage**.
2. Select **Internal WebDAV**, and click **Save**.

External Azure Storage

To use external Azure file storage for your Pivotal Application Service (PAS) filestore, perform the following steps:

1. Select the **External AzureStorage** option.

Configure your Cloud Controller's filesystem*

☐ Internal WebDAV (provided by Elastic Runtime)
 ☐ External S3-Compatible File Store (if you want to use a service like S3 or Ceph)
 ☐ External Google Cloud Storage
 ☒ External Azure Storage

Account Name *

pcfstorageaccount

Access Key *

.....

Buildpacks Container Name *

pcfbuildpacks

Droplets Container Name *

pcfdroplets

Packages Container Name *

pcfpackages

Resources Container Name *

pcfresources

2. To create a new storage account and storage containers for the PAS filestore, perform the following steps.
 - In the Azure Portal, navigate to the **Storage accounts** tab.
 - Click on the plus icon to add a new storage account.
 - In the **Name** field, enter a unique name (all lowercase, 3 to 24 alphanumeric characters) for the storage account.
 - For the **Deployment model**, select **Resource manager**.
 - For **Account kind**, select **General purpose**.

- For **Performance**, select **Standard**.
 - From the **Replication** dropdown, select **Locally-redundant storage (LRS)**.
 - For **Storage service encryption**, select **Disabled**.
 - From the **Subscription** dropdown, select the subscription where you want to deploy PCF resources.
 - For **Resource group**, select **Use existing** and enter the name of the resource group where you deployed PAS.
 - From **Location** the dropdown, select the **Location** where you are deploying PCF.
 - Click **Create**.
 - After the storage account is created, select the new storage account from the dashboard.
 - Navigate to the **Blob Service** section of the storage account, and then click on **Containers** to create one or more containers in this storage account for buildpacks, droplets, resources, and packages.
 - For each container that you create, set the **Access type** to **Private**.
3. In PAS, enter the name of the storage account you created for **Account Name**.
 4. In the **Secret Key** field, enter one of the access keys provided for the storage account. To obtain a value for this fields, visit the Azure Portal, navigate to the **Storage accounts** tab and click on **Access keys**.
 5. For the **Buildpacks Container Name**, enter the container name for storing your app buildpacks.
 6. For **Droplets Container Name**, enter the container name for your app droplet storage. Pivotal recommends that you use a unique container name, but you can use the same container name as the previous step.
 7. For **Resources Container Name**, enter the container name for resources. Pivotal recommends that you use a unique container name, but you can use the same container name as the previous step.
 8. For **Packages Container Name**, enter the container name for packages. Pivotal recommends that you use a unique container name, but you can use the same container name as the previous step.
 9. Click **Save**.

 **Note:** To enable backup and restore of your PAS tile that uses S3 compatible blobstore, see [Enable External Blobstore Backups](#).

Other IaaS Storage Options

[Google Cloud Storage](#) and [External S3-Compatible File Storage](#) are also available as file storage options but are not recommended for typical PCF on Azure installations.

Step 14: (Optional) Configure System Logging

You can configure system logging in PAS to forward log messages from PAS component VMs to an external service. Pivotal recommends forwarding logs to an external service for use in troubleshooting.

 **Note:** The following instructions explain how to configure system logging for PAS component VMs. To forward logs from PCF tiles to an external service, you must also configure system logging in each tile. See the documentation for the given tiles for information about configuring system logging.

To configure system logging in PAS, do the following:

1. In the PAS **Settings** tab, select the **System Logging** pane. The following image shows the **System Logging** pane.

Optionally configure rsyslog to forward platform component logs to an external service. If you do not fill these fields, platform logs will not be forwarded but will remain available on the component VMs and for download via Ops Manager.

Address

Port

Transport Protocol

Encrypt syslog using TLS?*

- ☒ No
☐ Yes

Syslog Drain Buffer Size (# of messages) *

☒ Include container metrics in SysLog Drains

☒ Enable Cloud Controller security event logging

☐ Use TCP for file forwarding local transport

☒ Don't Forward Debug Logs

Custom rsyslog Configuration

Save

2. For **Address**, enter the IP address of the syslog server.
3. For **Port**, enter the port of the syslog server. The default port for a syslog server is `514`.

 **Note:** The host must be reachable from the PAS network and accept UDP or TCP connections. Ensure the syslog server listens on external interfaces.

4. For **Transport Protocol**, select a transport protocol for log forwarding.
5. For **Encrypt syslog using TLS?**, select **Yes** to use TLS encryption when forwarding logs to a remote server.
 - a. For **Permitted Peer**, enter either the name or SHA1 fingerprint of the remote peer.
 - b. For **TLS CA Certificate**, enter the TLS CA certificate for the remote server.
6. For **Syslog Drain Buffer Size**, enter the number of messages from the Loggregator Agent that the Doppler server can store before it begins to drop messages. See the [Loggregator Guide for Cloud Foundry Operators](#) topic for more details.
7. Disable the **Include container metrics in Syslog Drains** checkbox to prevent the [CF Drain CLI plugin](#) from including app container metrics in syslog drains. This feature is enabled by default.

8. Enable the **Enable Cloud Controller security event logging** checkbox to include security events in the log stream. This feature logs all API requests, including the endpoint, user, source IP address, and request result, in the Common Event Format (CEF).
9. Enable the **Use TCP for file forwarding local transport** checkbox to transmit logs over TCP. This prevents log truncation, but may cause performance issues.
10. Disable the **Don't Forward Debug Logs** checkbox to forward DEBUG syslog messages to an external service. This checkbox is enabled by default.

Note: Some PAS components generate a high volume of DEBUG syslog messages. Enabling the **Don't Forward Debug Logs** checkbox prevents PAS components from forwarding the DEBUG syslog messages to external services. However, PAS still writes the messages to the local disk.

11. For **Custom rsyslog Configuration**, enter a custom syslog rule. For more information about adding custom syslog rules, see [Customizing Syslog Rules](#).
12. Click **Save**.

To configure Ops Manager for system logging, see the [Settings](#) section in the *Using the Ops Manager Interface* topic.

Step 15: (Optional) Customize Apps Manager

This section describes how to configure **Custom Branding** and **Apps Manager** to customize the appearance and functionality of Apps Manager. For more information about the **Custom Branding** configuration settings, see [Custom Branding Apps Manager](#).

1. Select **Custom Branding**. Use this section to configure the text, colors, and images of the interface that developers see when they log in, create an account, reset their password, or use Apps Manager.

Customize colors, images, and text for Apps Manager and the Cloud Foundry login portal.

Company Name

Accent Color

Marketplace Name

Customize Sidebar Links Add

You may configure up to 10 links in the Apps Manager sidebar.

- ▶ Marketplace 🗑️
- ▶ Docs 🗑️
- ▶ Tools 🗑️

Apps Manager Memory Usage (MB) (min: 128)

Invitations Memory Usage (MB) (min: 256)

Apps Manager Polling Interval *

30

Apps manager polling interval in seconds. As a workaround to reduce load on the Cloud Controller API, increase the polling interval or set to 0 to stop polling. Values between 0 and 30 will default to 30 seconds.

Save

4. Select **Enable Invitations** to enable invitations in Apps Manager. Space Managers can invite new users for a given space, Org Managers can invite new users for a given org, and Admins can invite new users across all orgs and spaces. See the [Inviting New Users](#) section of the *Managing User Roles with Apps Manager* topic for more information.
5. Select **Display Marketplace Service Plan Prices** to display the prices for your services plans in the Marketplace.
6. Enter the **Supported currencies as JSON** to appear in the Marketplace. Use the format `{ "CURRENCY-CODE": "SYMBOL" }`. This defaults to `{ "usd": "$", "eur": "€" }`.
7. Use **Product Name**, **Marketplace Name**, and **Customize Sidebar Links** to configure page names and sidebar links in the **Apps Manager** and **Marketplace** pages.
8. The **Apps Manager Memory Usage (MB)** field sets the memory limit with which to deploy the Apps Manager app. Use this field to increase the memory limit if the app fails to start with an `out of memory` error.
9. The **Invitations Memory Usage (MB)** field sets the memory limit with which to deploy the Invitations app. Use this field to increase the memory limit if the app fails to start with an `out of memory` error.

10. The **Apps Manager Polling Interval** field provides a temporary fix if Apps Manager usage degrades Cloud Controller response times. In this case, you can use this field to reduce the load on the Cloud Controller and ensure Apps Manager remains available while you troubleshoot the Cloud Controller. Pivotal recommends that you do not keep this field modified as a long term fix because it can degrade Apps Manager performance. You can optionally do the following:

- Increase the polling interval above the default of `30` seconds.

 **Note:** If you enter a value between `0` and `30`, the field is automatically set to `30`.

- Disable polling by entering `0`. This stops Apps Manager from refreshing data automatically, but users can update displayed data by reloading Apps Manager manually.

11. Click **Save** to save your settings in this section.

Step 16: (Optional) Configure Email Notifications

PAS uses SMTP to send invitations and confirmations to Apps Manager users. You must complete the **Email Notifications** page if you want to enable end-user self-registration.

1. Select **Email Notifications**.

Configure Simple Mail Transfer Protocol for the Notifications application to send email notifications about your deployment. This application is deployed as an errand in Elastic Runtime. If you do not need this service, leave this section blank and disable the Notifications and Notifications UI errands.

From Email

Address of SMTP Server

Port of SMTP Server

SMTP Server Credentials

[Change](#)

☒ SMTP Enable Automatic STARTTLS

SMTP Authentication Mechanism*

SMTP CRAMMD5 secret

Save

2. Enter your reply-to and SMTP email information.

 **Note:** For GCP, you must use port `2525`. Ports `25` and `587` are not allowed on GCP Compute Engine.

3. Verify your authentication requirements with your email administrator and use the **SMTP Authentication Mechanism** dropdown to select `None`, `Plain`, or `CRAMMD5`. If you have no SMTP authentication requirements, select `None`.

- If you selected `CRAMMD5` as your authentication mechanism, enter a secret in the **SMTP CRAMMD5 secret** field.
- Click **Save**.

 **Note:** If you do not configure the SMTP settings using this form, the administrator must create orgs and users using the cf CLI. See [Creating and Managing Users with the cf CLI](#) for more information.

Step 17: Configure Cloud Controller

- Click **Cloud Controller**.

Configure the Cloud Controller

Cloud Controller DB Encryption Key

Secret

Enabling CF API Rate Limiting will prevent API consumers from overwhelming the platform API servers. Limits are imposed on a per-user or per-client basis and reset on an hourly interval. *

☐ Enable
☒ Disable

Save

- Enter your **Cloud Controller DB Encryption Key** if all of the following are true:

- You deployed Pivotal Application Service (PAS) previously.
- You then stopped PAS or it crashed.
- You are re-deploying PAS with a backup of your Cloud Controller database.

See [Backing Up Pivotal Cloud Foundry](#) for more information.

- CF API Rate Limiting prevents API consumers from overwhelming the platform API servers. Limits are imposed on a per-user or per-client basis and reset on an hourly interval.

To disable CF API Rate Limiting, select **Disable** under **Enable CF API Rate Limiting**. To enable CF API Rate Limiting, perform the following steps:

- Under **Enable CF API Rate Limiting**, select **Enable**.
- For **General Limit**, enter the number of requests a user or client is allowed to make over an hour interval for all endpoints that do not have a custom limit. The default value is `2000`.
- For **Unauthenticated Limit**, enter the number of requests an unauthenticated client is allowed to make over an hour interval. The default value is `100`.

- Click **Save**.

Step 18: Configure Smoke Tests

The Smoke Tests errand runs basic functionality tests against your Pivotal Application Service (PAS) deployment after an installation or update. In this section, choose where to run smoke tests. In the **Errands** section, you can choose whether or not to run the Smoke Tests errand.

- Select **Smoke Tests**.
- If you have a shared apps domain, select **Temporary space within the system organization**, which creates a temporary space within the `system` organization for running smoke tests and deletes the space afterwards. Otherwise, select **Specified org and space** and complete the fields to specify

where you want to run smoke tests.

Specify a Cloud Foundry organization and space where smoke tests can run if in the future you delete your Elastic Runtime deployment domains.

Choose where to deploy applications when running the smoke tests *

☐ Temporary space within the system organization (This is deleted after smoke tests finish.)

☒ Specified org and space (The org and space must have a domain available for routing.)

Organization *

Space *

Domain *

Save

3. Click **Save**.

Step 19: (Optional) Enable Advanced Features

The **Advanced Features** section of Pivotal Application Service (PAS) includes new functionality that may have certain constraints. Although these features are fully supported, Pivotal recommends caution when using them in production environments.

Diego Cell Memory and Disk Overcommit

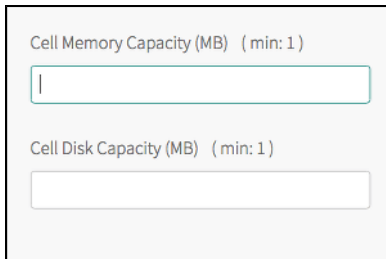

If your apps do not use the full allocation of disk space and memory set in the **Resource Config** tab, you might want use this feature. These fields control the amount to overcommit disk and memory resources to each Diego Cell VM.

For example, you might want to use the overcommit if your apps use a small amount of disk and memory capacity compared to the amounts set in the **Resource Config** settings for **Diego Cell**.

 **Note:** Due to the risk of app failure and the deployment-specific nature of disk and memory use, Pivotal has no recommendation about how much, if any, memory or disk space to overcommit.

To enable overcommit, do the following:

1. Select **Advanced Features**.

Cell Memory Capacity (MB) (min: 1)

Cell Disk Capacity (MB) (min: 1)

2. Enter the total desired amount of Diego cell memory value in the **Cell Memory Capacity (MB)** field. Refer to the **Diego Cell** row in the **Resource Config** tab for the current Cell memory capacity settings that this field overrides.
3. Enter the total desired amount of Diego cell disk capacity value in the **Cell Disk Capacity (MB)** field. Refer to the **Diego Cell** row in the **Resource Config** tab for the current Cell disk capacity settings that this field overrides.
4. Click **Save**.

 **Note:** Entries made to each of these two fields set the total amount of resources allocated, not the overage.

Whitelist for Non-RFC-1918 Private Networks

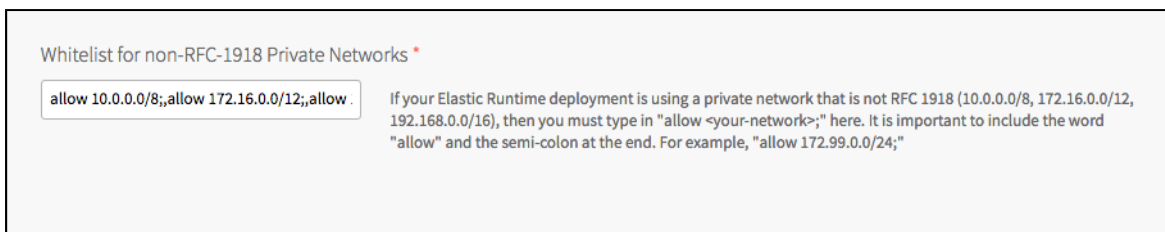

Some private networks require extra configuration so that internal file storage (WebDAV) can communicate with other PCF processes.

The **Whitelist for non-RFC-1918 Private Networks** field is provided for deployments that use a non-RFC 1918 private network. This is typically a private network other than `10.0.0.0/8`, `172.16.0.0/12`, or `192.168.0.0/16`.

Most PCF deployments do not require any modifications to this field.

To add your private network to the whitelist, do the following:

1. Select **Advanced Features**.
2. Append a new `allow` rule to the existing contents of the **Whitelist for non-RFC-1918 Private Networks** field.

Whitelist for non-RFC-1918 Private Networks *

`allow 10.0.0.0/8;;allow 172.16.0.0/12;;allow .`

If your Elastic Runtime deployment is using a private network that is not RFC 1918 (10.0.0.0/8, 172.16.0.0/12, 192.168.0.0/16), then you must type in "allow <your-network>;" here. It is important to include the word "allow" and the semi-colon at the end. For example, "allow 172.99.0.0/24;"

Include the word `allow`, the network CIDR range to allow, and a semi-colon (`;`) at the end. For example: `allow 172.99.0.0/24;`

3. Click **Save**.

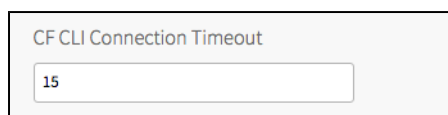

CF CLI Connection Timeout

The **CF CLI Connection Timeout** field allows you to override the default five second timeout of the Cloud Foundry Command Line Interface (cf CLI) used within your PCF deployment. This timeout affects the cf CLI command used to push PAS errand apps such as Notifications, Autoscaler, and Apps Manager.

Set the value of this field to a higher value, in seconds, if you are experiencing domain name resolution timeouts when pushing errands in PAS.

To modify the value of the **CF CLI Connection Timeout**, perform the following steps:

1. Select **Advanced Features**.

CF CLI Connection Timeout

2. Add a value, in seconds, to the **CF CLI Connection Timeout** field.

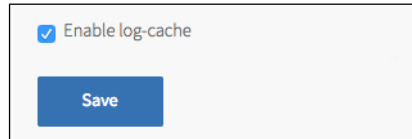

3. Click **Save**.

Log Cache

Log Cache is an in-memory caching layer for logs and metrics. This Loggregator feature lets users filter and query logs through a CLI or API endpoints. Cached logs are available on demand. For more information about Log Cache, see [Enable Log Cache](#) in the *Configuring Logging in PAS* topic.

To configure the **Enable log-cache** checkbox, do the following:

1. Select **Advanced Features**.

2. Select or deselect the **Enable log-cache** checkbox.
3. Click **Save**.

Database Connection Limits

You can configure the maximum number of concurrent database connections that diego and container networking components can have. Use the field beginning with **Maximum number of open connections...** for a given component. The placeholder values for each field are the default values.

When there are not enough connections available, such as during a time of heavy load, components may experience degraded performance and sometimes failure. To resolve or prevent this, you can increase and fine-tune database connection limits for the component.

Warning: Decreasing the value of this field for a component may affect the amount of time it takes for it to respond to requests.

Step 20: Configure Errands

Errands are scripts that Ops Manager runs automatically when it installs or uninstalls a product, such as a new version of Pivotal Application Service (PAS). There are two types of errands: *post-deploy errands* run after the product is installed, and *pre-delete errands* run before the product is uninstalled.

By default, Ops Manager always runs all errands.

The PAS tile **Errands** pane lets you change these run rules. For each errand, you can select **On** to run it always or **Off** to never run it.

For more information about how Ops Manager manages errands, see the [Managing Errands in Ops Manager](#) topic.

Note: Several errands, such as App Autoscaler and Notifications, deploy apps that provide services for your deployment. When one of these apps is running, selecting **Off** for the corresponding errand on a subsequent installation does not stop the app.

- **Smoke Test Errand** verifies that your deployment can do the following:
 - Push, scale, and delete apps
 - Create and delete orgs and spaces
- **Usage Service Errand** deploys the Pivotal Usage Service application, which Apps Manager depends on.
- **Apps Manager Errand** deploys Apps Manager, a dashboard for managing apps, services, orgs, users, and spaces. Until you deploy Apps Manager, you must perform these functions through the cf CLI. After Apps Manager has been deployed, Pivotal recommends setting this errand to **Off** for subsequent PAS deployments. For more information about Apps Manager, see the [Getting Started with the Apps Manager](#) topic.
- **Notifications Errand** deploys an API for sending email notifications to your PCF platform users.

Note: The Notifications app requires that you [configure SMTP](#) with a username and password, even if you set the value of **SMTP Authentication Mechanism** to `none`.

- **Notifications UI Errand** deploys a dashboard for users to manage notification subscriptions.

- **App Autoscaler Errand** enables you to configure your apps to automatically scale in response to changes in their usage load. See the [Scaling an Application Using Autoscaler](#) topic for more information.
- **NFS Broker Errand** enables you to use NFS Volume Services by installing the NFS Broker app in PAS. See the [Enabling NFS Volume Services](#) topic for more information.

Step 21: Configure Resources

1. Select **Resource Config**.

| Resource Config | | | | |
|---------------------|--------------|----------------------|---|---------------|
| JOB | INSTANCES | PERSISTENT DISK TYPE | VM TYPE | LOAD BALANCER |
| Consul | Automatic: 3 | Automatic: 1 GB | Automatic: Standard_F1s (cpu: 1, ram: 2 GB, disk: 1 | |
| NATS | Automatic: | None | Automatic: Standard_F1s (cpu: 1, ram: 2 GB, disk: 1 | |
| etcd | Automatic: 3 | Automatic: 1 GB | Automatic: Standard_F1s (cpu: 1, ram: 2 GB, disk: 1 | |
| File Storage | Automatic: 1 | Automatic: 100 GB | Automatic: Standard_F2s (cpu: 2, ram: 4 GB, disk: 3 | |
| MySQL Proxy | Automatic: | None | Automatic: Standard_F1s (cpu: 1, ram: 2 GB, disk: 1 | |
| MySQL Server | Automatic: 3 | Automatic: 100 GB | Automatic: Standard_DS11_v2 (cpu: 2, ram: 14 GB, | |
| Backup Prepare Node | 0 | Automatic: 200 GB | Automatic: Standard_F1s (cpu: 1, ram: 2 GB, disk: 1 | |
| UAA | Automatic: 2 | None | Automatic: Standard_F2s (cpu: 2, ram: 4 GB, disk: 3 | |
| Cloud Controller | Automatic: 2 | Automatic: 1 GB | Automatic: Standard_F2s (cpu: 2, ram: 4 GB, disk: 3 | |
| HAProxy | Automatic: 1 | None | Automatic: Standard_F1s (cpu: 1, ram: 2 GB, disk: 1 | |
| Router | Automatic: 3 | None | Automatic: Standard_F1s (cpu: 1, ram: 2 GB, disk: 1 | |

- Ensure a **Standard** VM type is selected for the **Router** VM. The PAS deployment fails if you select a **Basic** VM type.
- Enter the value of `web_lb_name` from your Terraform output in the **Resource Config** pane under **Load Balancers** for the **Router** job.
 - Enter the value of `diego_ssh_lb_name` from your Terraform output in the **Resource Config** pane under **Load Balancers** for the **Diego Brain** job.
 - Ensure that the **Internet Connected** checkboxes are deselected for all jobs.
 - Scale the number of instances as appropriate for your deployment.

Note: For a high availability deployment of PCF on Azure, Pivotal recommends scaling the number of each PAS job to a minimum of three (3) instances. Using three or more instances for each job creates a sufficient number of availability sets and fault domains for your deployment. For more information, see [Reference Architecture for Pivotal Cloud Foundry on Azure](#).

Step 22: (Optional) Scale Down and Disable Resources

Note: The **Resource Config** pane has fewer VMs if you are installing the [Small Footprint Runtime](#).

Note: The Small Footprint Runtime does not default to a highly available configuration. It defaults to the minimum configuration. If you want to make the Small Footprint Runtime highly available, scale the **Compute**, **Router**, and **Database** VMs to **3** instances and scale the **Control** VM to **2** instances.

Pivotal Application Service (PAS) defaults to a highly available resource configuration. However, you may need to perform additional procedures to make your deployment highly available. See the [Zero Downtime Deployment and Scaling in CF](#) and the [Scaling Instances in PAS](#) topics for more information.

If you do not want a highly available resource configuration, you must scale down your instances manually by using the dropdowns under **Instances** for each job.

By default, PAS also uses an internal filestore and internal databases. If you configure PAS to use external resources, you can disable the corresponding system-provided resources in Ops Manager to reduce costs and administrative overhead.

Complete the following procedures to disable specific VMs in Ops Manager:

1. Click **Resource Config**.
2. If you configured PAS to use an external S3-compatible filestore, enter in **Instances** in the **File Storage** field.
3. If you selected **External** when configuring the UAA, System, and CredHub databases, edit the following fields:
 - **MySQL Proxy**: Enter in **Instances**.
 - **MySQL Server**: Enter in **Instances**.
 - **MySQL Monitor**: Enter in **Instances**.
4. If you disabled TCP routing, enter **Instances** in the **TCP Router** field.
5. Click **Save**.

Step 23: Download Stemcell

This step is only required if your Ops Manager does not already have the stemcell version required by PAS. For more information about importing stemcells, see [Importing and Managing Stemcells](#).

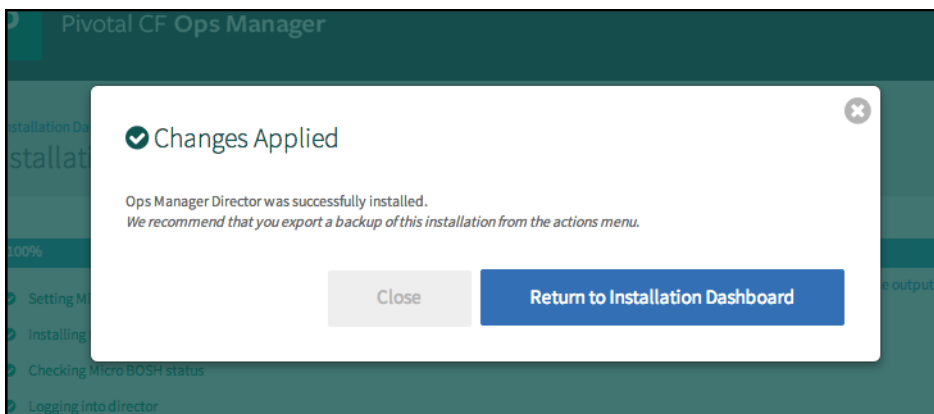

1. Open the [Stemcell product page](#) in the Pivotal Network. *Note, you may have to log in.*
2. Download the appropriate stemcell version targeted for your IaaS.
3. Navigate to **Stemcell Library** in the **Installation Dashboard**.
4. Click **Import Stemcell** to import the downloaded stemcell file.
5. When prompted, enable the Ops Manager product checkbox to stage your stemcell.
6. Click **Apply Stemcell to Products**.

Step 24: Complete the PAS Installation

1. Click the **Installation Dashboard** link to return to the Installation Dashboard.
2. Click **Apply Changes**. If the following ICMP error message appears, click **Ignore errors and start the install**.

The install process generally requires a minimum of 90 minutes to complete. The image shows the Changes Applied window that displays when the installation process successfully completes.

Troubleshooting PCF on Azure

Page last updated:

This topic describes how to troubleshoot known issues when deploying or running Pivotal Cloud Foundry (PCF) on Azure.

Installation Issues

Cannot Copy the Ops Manager Image

Symptom

Cannot copy the Ops Manager image into your storage account as part of *Step 4: Boot Ops Manager* in [Deploying Ops Manager on Azure Manually](#).

Explanation

You have an outdated version of the Azure CLI. You need the Azure CLI version 2.0.0 or greater. Run `az --version` from the command line to display your current Azure CLI version.

Solution

Install the Azure CLI 2.0 by following the instructions for your operating system in the [Azure documentation](#).

Deployment Fails at “create-env”

Symptom

After clicking **Apply Changes** to install Ops Manager and PAS, the deployment fails at `create-env` with an error message similar to the following:

```
Command 'deploy' failed:
Deploying:
Creating instance 'bosh/0':
Waiting until instance is ready:
Starting SSH tunnel:
Parsing private key file '/tmp/bosh_ec2_private_key.pem':
asn1: structure error: tags don't match (16 vs {class:3 tag:28 length:127
isCompound:false}) {optional:false explicit:false application:false
defaultValue:<nil> tag:<nil> stringType:0 timeType:0 set:false omitEmpty:false} pkcs1PrivateKey @2
===== 2016-09-29 16:28:22 UTC Finished "bosh create-env"
/var/tempest/workspaces/default/deployments/bosh.yml";
Duration: 328s; Exit Status: 1
Exited with 1.
```

Explanation

You provided a passphrase when creating your key pair in *Step 4: Boot Ops Manager* of [Deploying Ops Manager on Azure Manually](#).

Solution

Create a new key pair with no passphrase and redo the installation. See *Step 4: Boot Ops Manager* in [Deploying Ops Manager on Azure Manually](#).

Insufficient External Database Permissions

Upgrade issues can be caused when the external database user used for the network policy DB is given insufficient permissions. To avoid this upgrade issue, ensure that the networkpolicyserver database user has the

ALL
PRIVILEGES

permission.

Operation Issues

Slow Performance or Timeouts

Symptom

Developers suffer from slow performance or timeouts when pushing or managing apps, and end users suffer from slow performance or timeouts when accessing apps

Explanation

The Azure Load Balancer (ALB) disconnects active TCP connections lying idle for over four minutes.

Solution

To mitigate slow performance or timeouts, the default value of the **Router Timeout to Backends (in seconds)** field is set to 900 seconds. This default value is set high to mitigate performance issues but operators should tune this parameter to fit their infrastructure.

To edit the **Router Timeout to Backends (in seconds)** field:

1. Select the Pivotal Application Service (PAS) tile that is located within your **Installation Dashboard**.
2. Select the **Networking** tab.
3. Enter your desired time, in seconds, within the **Router Timeout to Backends (in seconds)** field.

Router Timeout to Backends (in seconds) (min: 1) *

Timeout for connections from Router (and HAProxy, if you use it) to applications and system components. Increase this to accommodate larger uploads over connections with high latency.

4. Click **Save**.

Service Instance Creation Times Out

Symptom

You are unable to provision a service instance of a Java or Go service. `cf create-service` fails with error

Failure provisioning service instance... Timed out after 8 minutes...

or similar.

Explanation

HTTP libraries for Java and Go, running with default settings, prune idle (for 240 seconds) connections from their connection pool without sending a TCP reset message back to the client service broker. This removes the ability of the broker to provision new service instances.

Solution

In the PAS tile **Configure Networking** pane, set **Frontend Idle Timeout** to 240 seconds or less, so that Cloud Foundry regenerates the front-end connection before it times out.

See the Knowledge Base article [Azure Networking Connection Idle for more than Four minutes](#) [↗](#) for details.

Deleting a PCF on Azure Installation

Page last updated:

When you deploy [Pivotal Cloud Foundry](#) (PCF) to Azure, you provision a set of resources. This topic describes how to delete the resources associated with a PCF deployment.

The fastest way to remove resources is to delete the resource group, or resource groups, associated with your PCF on Azure installation.

Delete the Resource Group

Perform the following steps to delete a resource group:

1. Navigate to the [Azure Portal](#).
2. Within your subscription, select **Resource Groups**.
3. Click on the resource group you wish to delete.
4. In the details pane for the resource group, click on the trash can icon. Review the information in the confirmation screen before proceeding.
5. To confirm deletion, type in the resource group name and click **Delete**.

For more information about managing resource groups in Azure, see the [Azure documentation](#).

Upgrading BOSH Director on Azure

This topic describes how to upgrade BOSH Director for Pivotal Cloud Foundry (PCF) on Azure.

Complete the tasks in this topic as part of the Ops Manager upgrade process. For more information, see [Upgrading Pivotal Cloud Foundry](#).

Overview

In this procedure, you create an Ops Manager VM instance to host the upgraded version of Ops Manager. Then, to complete the Ops Manager upgrade, you export your existing Ops Manager installation onto this new VM.

 **Note:** The Azure portal sometimes displays the names of resources with incorrect capitalization. Always use the Azure CLI to retrieve the correctly capitalized name of a resource.

To create an Ops Manager VM instance, do the following:

1. Export environment variables. See [Export Environment Variables](#).
2. Copy the Ops Manager image into your storage account. See [Copy the Ops Manager Image](#).
3. Configure the Ops Manager IP Address. See [Configure Ops Manager IP Address](#).
4. Create Ops Manager VM instance. See [Create Ops Manager VM Instance](#).

Prerequisites

To complete the Ops Manager upgrade, you must have your Ops Manager decryption passphrase. You defined this decryption passphrase during the initial installation of Ops Manager.

Export Environment Variables

Export the `connectionString` variable for your Azure account and assign it to a new environment variable. You use the `connectionString` environment variable when you copy the Ops Manager image in the following procedure.

To export environment variables, do the following:

1. Install the Azure CLI 2.0 by following the instructions for your operating system in the [Azure documentation](#).
2. Set your cloud:

```
$ az cloud set --name AzureCloud
```

If you deployed PCF in an environment other than Azure Cloud, consult the following list:

- For Azure China, replace `AzureCloud` with `AzureChinaCloud`. If logging in to `AzureChinaCloud` fails with a `CERT_UNTRUSTED` error, use the latest version of node, 4.x or later.
- For Azure Government Cloud, replace `AzureCloud` with `AzureUSGovernment`.
- For Azure Germany, replace `AzureCloud` with `AzureGermanCloud`.

3. Log in:

```
$ az login
```

Authenticate by navigating to the URL in the output, entering the provided code, and clicking your account.

4. Ensure that the following environment variables are set to the names of the resources you created when deploying Ops Manager as part of the procedures in [Deploying Ops Manager on Azure Manually](#).
 - `$RESOURCE_GROUP`: This should be set to the name of your resource group. Run `az group list` to list the resource groups for your subscription.

- `$LOCATION` : This should be set to your location, such as `westus` . For a list of available locations, run `az account list-locations` .
- `$STORAGE_NAME` : This should be set to your BOSH storage account name. Run `az storage account list` to list your storage accounts.

5. Retrieve the connection string for the account.

```
$ az storage account show-connection-string \
--name $STORAGE_NAME --resource-group $RESOURCE_GROUP
```

The command returns output similar to the following:

```
{
  "connectionString": "DefaultEndpointsProtocol=https;EndpointSuffix=core.windows.net;AccountName=cfdocsboshstorage;AccountKey=EXAMPLExXXXXXXXXXXXXLprnc5igFyYWsgq0"
}
```

6. From the `data:` field in the output above, record the full value of `connectionString` from the output above, starting with and including `DefaultEndpointsProtocol=` .
7. Export the value of `connectionString` as the environment variable `$AZURE_STORAGE_CONNECTION_STRING` .

```
$ export AZURE_STORAGE_CONNECTION_STRING="YOUR-ACCOUNT-KEY-STRING"
```

Copy the Ops Manager Image

Copy the Ops Manager image into your storage account. You use the Ops Manager image to create the VM that hosts that the new version of Ops Manager.

To copy the Ops Manager image into your storage account, do the following:

1. Navigate to [Pivotal Network](#) and download the release of **Pivotal Cloud Foundry Ops Manager for Azure** you want to upgrade to.
2. View the downloaded PDF and locate the Ops Manager image URL appropriate for your region.
3. Export the Ops Manager image URL as an environment variable.

```
$ export OPS_MAN_IMAGE_URL="YOUR-OPS-MAN-IMAGE-URL"
```

This command overrides the old Ops Manager image URL with the new Ops Manager image URL.

4. Copy the Ops Manager image into your storage account. For compatibility when upgrading to future versions of Ops Manager, choose a unique name for the image that includes the Ops Manager version number. For example, replace `opsman-image-version` in the following examples with `opsman-image-2.0.1` .

```
$ az storage blob copy start --source-uri $OPS_MAN_IMAGE_URL \
--connection-string $AZURE_STORAGE_CONNECTION_STRING \
--destination-container opsmanager \
--destination-blob opsman-image-version.vhd
```

5. Copying the image may take several minutes. Run the following command and examine the output under `"copy"` :

```
$ az storage blob show --name opsman-image-version.vhd \
--container-name opsmanager \
--account-name $STORAGE_NAME
...
"copy": {
  "completionTime": "2017-06-26T22:24:11+00:00",
  "id": "b9c8b272-a562-4574-baa6-fla04afcefd",
  "progress": "53687091712/53687091712",
  "source": "https://opsmanagerwestus.blob.core.windows.net/images/ops-manager-2.0.x.vhd",
  "status": "success",
  "statusDescription": null
},
```

When `status` reads `success` , continue to the next step.

Configure Ops Manager IP Address

Remove the old Ops Manager VM and record the IP address for the Ops Manager network interface. You use this IP address when creating the new Ops Manager VM that hosts the upgraded version of Ops Manager.

To configure the Ops Manager IP address, do one of the following:

- [Reuse the existing dynamic public IP address.](#)
- [Use a new dynamic public IP address.](#)

Reuse Existing Dynamic Public IP Address

To reuse an existing dynamic public IP address, do the following:

1. List your VMs and record the name of your Ops Manager VM:

```
$ az vm list
```

2. Delete your old Ops Manager VM:

```
$ az vm delete --name YOUR-OPS-MAN-VM --resource-group $RESOURCE_GROUP
```

3. List your network interfaces and record the name of the Ops Manager network interface:

```
$ az resource list --resource-group $RESOURCE_GROUP \
--resource-type Microsoft.Network/networkInterfaces
```

Use a New Dynamic Public IP Address

To use a new dynamic public IP address, do the following:

1. Create a new public IP address named `ops-manager-ip-new`.

```
$ az network public-ip create --name ops-manager-ip-new \
--resource-group $RESOURCE_GROUP --location $LOCATION \
--allocation-method Static
{
  "publicIp": {
    "dnsSettings": null,
    "etag": "W/\"4450ebe2-9e97-4b17-9ef2-44838339c661\"",
    "id": "/subscriptions/995b7eed-77cf-45ff-a5c9-1a405ffb8243/resourceGroups/cf-docs/providers/Microsoft.Network/publicIPAddresses/ops-manager-ip-new",
    "idleTimeoutInMinutes": 4,
    "ipAddress": "40.83.148.183",
    "ipConfiguration": null,
    "location": "westus",
    "name": "ops-manager-ip-new",
    "provisioningState": "Succeeded",
    "publicIpAddressVersion": "IPv4",
    "publicIpAllocationMethod": "Static",
    "resourceGroup": "cf-docs",
    "resourceGuid": "950d4831-1bec-42da-8a79-959beddea9dd",
    "tags": null,
    "type": "Microsoft.Network/publicIPAddresses"
  }
}
```

2. Record the value for `ipAddress` from the output above. This is the public IP address of Ops Manager.

3. Create a network interface for Ops Manager.

```
$ az network nic create --vnet-name pcf-net \
--subnet pcf --network-security-group opsmgr-nsg \
--private-ip-address 10.0.0.5 \
--public-ip-address ops-manager-ip-new \
--resource-group $RESOURCE_GROUP \
--name ops-manager-nic-new --location $LOCATION
```

4. Shut down your old Ops Manager VM, if it still exists:

```
$ az vm deallocate --name ops-manager --resource-group $RESOURCE_GROUP
```

If your Ops Manager VM is not named `ops-manager`, provide the correct name. To list all VMs in your account, use `az vm list`.

5. Update your DNS record to point to your new public IP address of Ops Manager.

Create Ops Manager VM Instance

Create an Ops Manager VM instance to host the new version of Ops Manager.

To create an Ops Manager VM instance, do the following:

1. To use the key pair from your previous Ops Manager, locate the path to the file on your local machine. To create a new key pair, enter the following command:

```
$ ssh-keygen -t rsa -f opsman -C ubuntu
```

When prompted for a passphrase, press the `enter` key to provide an empty passphrase.

2. Create the Ops Manager VM.

- If you are using unmanaged disks, run the following command to create your Ops Manager VM, replacing `PATH-TO-PUBLIC-KEY` with the path to your public key .pub file, and replacing `opsman-image-version` with the version of Ops Manager you are deploying, for example

```
opsman-image-2.0.1 :
```

```
$ az vm create --name opsman-version --resource-group $RESOURCE_GROUP \
--location $LOCATION \
--nics opsman-nic \
--image https://$STORAGE_NAME.my-azure-instance.com/opsmanager/opsman-image-version.vhd \
--os-disk-name opsman-version-osdisk \
--os-disk-size-gb 128 \
--os-type Linux \
--use-unmanaged-disk \
--storage-account $STORAGENAME \
--storage-container-name opsmanager \
--admin-username ubuntu \
--ssh-key-value PATH-TO-PUBLIC-KEY
```

Replace `my-azure-instance.com` with the URL of your Azure instance. Find the complete source URL in the Azure UI by viewing the **Blob properties** of the Ops Manager image you created earlier in this procedure.

- If you are using Azure managed disks, perform the following steps, replacing `opsman-image-version` with the version of Ops Manager you are deploying, for example `opsman-image-2.0.1` .:

1. Create a managed image from the Ops Manager VHD file:

```
$ az image create --resource-group $RESOURCE_GROUP \
--name opsman-image-version \
--source https://$STORAGE_NAME.blob.core.windows.net/opsmanager/opsman-image-version.vhd \
--location $LOCATION \
--os-type Linux
```

If you are using Azure China, Azure Government Cloud, or Azure Germany, replace `blob.core.windows.net` with the following:

- For Azure China, use `blob.core.chinacloudapi.cn`. See the [Azure documentation](#) for more information.
- For Azure Government Cloud, use `blob.core.usgovcloudapi.net`. See the [Azure documentation](#) for more information.
- For Azure Germany, use `blob.core.cloudapi.de`. See the [Azure documentation](#) for more information.

2. Create your Ops Manager VM, replacing `PATH-TO-PUBLIC-KEY` with the path to your public key `.pub` file, and replacing `opsman-version` and `opsman-image-version` with the version of Ops Manager you are deploying, for example `opsman-2.0.1`, `opsman-2.0.1-osdisk`, and `opsman-image-2.0.1`.

```
$ az vm create --name opsman-version --resource-group $RESOURCE_GROUP \
--location $LOCATION \
--nics opsman-nic \
--image opsman-image-version \
--os-disk-name opsman-version-osdisk \
--admin-username ubuntu \
--size Standard_DS2_v2 \
--storage-sku Standard_LRS \
--ssh-key-value PATH-TO-PUBLIC-KEY
```

3. If you have deployed more than one tile in this Ops Manager installation, perform the following steps to increase the size of the Ops Manager VM disk. You can repeat this process and increase the disk again at a later time if necessary.

 **Note:** If you use Azure Stack, you must increase the Ops Manager VM disk size using the Azure Stack UI.

- a. Run the following command to stop the VM and detach the disk, replacing `opsman-version` with the version of Ops Manager you are deploying, for example `opsman-2.0.1`:

```
$ az vm deallocate --name opsman-version \
--resource-group $RESOURCE_GROUP
```

- b. Run the following command to resize the disk to 128 GB, replacing `opsman-version` with the version of Ops Manager you are deploying, for example `opsman-2.0.1`:

```
$ az disk update --size-gb 128 --name opsman-version-osdisk \
--resource-group $RESOURCE_GROUP
```

- c. Run the following command to start the VM, replacing `opsman-version` with the version of Ops Manager you are deploying, for example `opsman-2.0.1`:

```
$ az vm start --name opsman-version --resource-group $RESOURCE_GROUP
```

Next Steps

After you complete this procedure, continue the upgrade instructions in [Upgrading Pivotal Cloud Foundry](#) topic.

Installing Pivotal Cloud Foundry on GCP

Page last updated:

This topic describes how to install [Pivotal Cloud Foundry](#) (PCF) on Google Cloud Platform (GCP).

It includes resource requirements, prerequisites, instructions for installing PCF on GCP, and additional resources.

Overview

You can install PCF on GCP with either the Pivotal Application Service (PAS) or Pivotal Container Service (PKS) runtime. There are resource requirements specific to each runtime. Ensure you meet the requirements for your runtime and the requirements specific to GCP before installing PCF on GCP.

Requirements

This section lists the following resource requirements for installing PCF on GCP:

- General PCF resource requirements. See [PCF Resource Requirements](#).
- GCP-specific resource requirements. See [GCP Resource Requirements](#).

PCF Resource Requirements

This section lists PCF resource requirements for installing PCF on GCP. It includes general PCF resource requirements for both the PAS and PKS runtimes.

View one of the following, depending on your PCF runtime:

- PAS-specific PCF resource requirements. See [PAS Resource Requirements](#).
- PKS-specific PCF resource requirements. See [PKS Resource Requirements](#).

PAS Resource Requirements

The following are general resource requirements for deploying and managing a PCF deployment with Ops Manager and PAS:

- PAS requires sufficient IP allocation. The following lists the minimum required IP allocations:
 - One static IP address for either HAProxy or one of your Gorouters
 - One static IP address for each job in the Ops Manager tile. See the Ops Manager **Resource Config** pane for each tile for a full list.
 - One static IP address for each job listed below:
 - Consul
 - NATS
 - File Storage
 - MySQL Proxy
 - MySQL Server
 - Backup Restore Node
 - HAProxy
 - Router
 - MySQL Monitor
 - Diego Brain
 - TCP Router
 - One IP for each VM instance created by the service.
 - An additional IP address for each compilation worker. Use the following formula to determine the total IPs required:

$$\text{IPs needed} = \text{static IPs} + \text{VM instances} + \text{compilation workers}$$
 - Pivotal recommends that you allocate at least 36 dynamic IP addresses when deploying Ops Manager and PAS. BOSH requires additional dynamic IP addresses during installation to compile and deploy VMs, install PAS, and connect to services.
- Pivotal recommends using a network without DHCP for deploying PAS VMs.

 **Note:** If you have DHCP, refer to the [Troubleshooting Guide](#) to avoid issues with your installation.

PKS Resource Requirements

For PKS-specific resource requirements, see [GCP Prerequisites and Resource Requirements](#).

GCP Resource Requirements

The following are GCP-specific resource requirements for installing PCF on GCP:

- Installing PCF on GCP requires a minimum of the following VM instance limits in your GCP account. The number of VMs required depends on the number of tiles and availability zones you plan to deploy. The following VM guidelines apply to the PAS and Small Footprint PAS runtimes:
 - PAS:** At a minimum, a new GCP deployment requires the following `custom` VMs for PAS and Ops Manager:

| VM Count | vCPU Count per VM | RAM (GB) |
|----------|-------------------|----------|
| 30 | 1 | 1 |
| 3 | 1 | 2 |
| 4 | 2 | 4 |
| 3 | 2 | 8 |
| 3 | 4 | 16 |

 **Note:** If you are deploying a test or sandbox PCF that does not require high availability, then you can scale down the number of VM instances in your deployment. For more information, see [Scaling PAS](#).

- Small Footprint PAS:** At a minimum, a new GCP deployment requires the following VMs to run Small Footprint PAS:

| | VM Type | VM Count | vCPU Count per VM | RAM (GB) | Notes |
|---------------------|-------------|----------|-------------------|----------|------------------------------------|
| Small Footprint PAS | micro | 12 | 1 | 1 | Add 1 to VM count if using HAProxy |
| | small | 3 | 1 | 2 | |
| | xlarge.disk | 1 | 4 | 16 | |
| | xlarge | 1 | 4 | 16 | |
| | medium.mem | 1 | 1 | 6 | |
| | large.disk | 1 | 2 | 8 | |
| Ops Manager | large.disk | 1 | 2 | 8 | |
| | large.cpu | 4 | 4 | 4 | |

- PKS:** See [GCP Prerequisites and Resource Requirements](#).
- (PAS-only) Your GCP project must have sufficient quota to deploy all the VMs needed to install PCF with PAS. For a list of suggested quotas, see [Recommended GCP Quotas](#).

Prerequisites

To install PCF on GCP, you must do the following:

- Install the Google Cloud SDK on your machine and authenticate it to your GCP account. To download the Google Cloud SDK, see [Google Cloud SDK](#).
- Increase or remove the VM instance limits in your GCP account. For VM instance requirements, see [GCP Resource Requirements](#).
- Update your GCP account with the following required permissions:
 - The following permissions are required to create firewalls, networks, load balancers, and other resources:
 - Compute Engine > Compute Instances Admin (beta)
 - Compute Engine > Compute Network Admin
 - Compute Engine > Compute Security Admin

- To use Google Cloud Storage (GCS) for Cloud Controller file storage, the following permission is required to create buckets:
 - **Storage > Storage Admin**
- To use Cloud DNS, the following permission is required to add and modify DNS entries:
 - **Project > Editor**
- Create an SSL certificate for your PCF domain.

 **Note:** To deploy PCF to a production environment, you must obtain a certificate from a certificate authority. Pivotal recommends using a self-signed certificate generated by Ops Manager for development and testing purposes only.

- Assign administrative rights to a domain for PCF. You need to be able to add wildcard records to this domain.
- Create a wildcard DNS record that points to your router or load balancer. Alternatively, you can use a service such as xip.io. For example, `203.0.113.0.xip.io`. Then, create at least one wildcard TLS certificate that matches the DNS record you configured.

 **Note:** With a wildcard DNS record, every hostname in your domain resolves to the IP address of your router or load balancer. For example, if you create a DNS record `*.example.com` pointing to your router, every app deployed to the `example.com` domain resolves to the IP address of your router.

- Create one or more NTP servers, if the NTP servers are not already provided by your GCP project.
- Install the most recent version of one of the following CLIs, depending on your PCF runtime:
 - **PAS:** The Cloud Foundry Command Line Interface (cf CLI). See [Cloud Foundry Command Line Interface](#) in GitHub.
 - **PKS:** The PKS CLI. See [Installing the PKS CLI](#).
- **(PAS-only)** Request a quota increase for your GCP project. For GCP quota requirements, see [GCP Resource Requirements](#). To request an increase, see [Quotas](#) in the GCP console.
- **(PAS-only)** Configure sufficient IP allocation. For more information about IP allocation requirements, see [PAS Resource Requirements](#).
- **(Optional) (PAS-only)** Configure external storage. Pivotal recommends using external storage if possible. For more information about how file storage location affects platform performance and stability during upgrades, see [Configure File Storage](#).
- **(Optional) (PAS and Ops Manager-only)** Configure external databases. Pivotal recommends using external databases in production deployments for BOSH Director and PAS. An external database must be configured to use the UTC timezone.
- **(Optional) (PAS and Ops Manager-only)** Configure external user stores. When you deploy PCF, you can select a SAML user store for Ops Manager or a SAML or LDAP user store for PAS, to integrate existing user accounts.

Install PCF on GCP

You can install PCF on GCP either manually or using Terraform.

To install PCF on GCP, do one of the following:

- Install PCF on GCP manually. See [Installing PCF on GCP Manually](#).
- Install PCF on GCP using Terraform. See [Install PCF on GCP Using Terraform](#).

Additional Resources

The following are additional resources related to installing PCF on GCP:

- For general authentication guidelines for GCP, see [GCP authentication documentation](#).
- For more information about troubleshooting the PCF on GCP infrastructure, see [Troubleshooting PCF on GCP](#).
- For production-level deployment options for PCF on GCP, see [Reference Architecture for Pivotal Cloud Foundry on GCP](#).
- For general certificate requirements for deploying PCF, see [Certificate Requirements](#).

Recommended GCP Quotas

Page last updated:

Default quotas on a new GCP subscription do not have enough quota for a typical production-level PCF deployment.

The following table lists recommended resource quotas for a single PCF deployment.

| Metric | Resource | Suggested Minimum Quota |
|-----------------------------------|----------|-------------------------|
| CPUs | Regional | 150 [*] |
| Firewall rules | Global | 15 |
| Forwarding rules | Global | 15 |
| Backend services | Global | 5 |
| Health checks | Global | 5 |
| Images | Global | 10 |
| Static IP addresses ^{**} | Regional | 5 |
| In-use IP addresses | Global | 5 |
| In-use IP addresses ^{**} | Regional | 5 |
| Networks | Global | 5 |
| Subnetworks | Global | 5 |
| Routes | Global | 20 |
| Target pools | Global | 5 |
| Target HTTP proxies | Global | 5 |
| Target HTTPS proxies | Global | 5 |
| Persistent Disk Standard (GB) | Regional | 15,000 |

^{*} Assuming a deployment with 100 app instances.

^{**} Assuming a SNAT topology.

To view production-level deployment options for PCF on GCP, see the [Reference Architecture for Pivotal Cloud Foundry on GCP](#).

For instructions on how to set up GCP resources required to deploy PCF, see [Preparing to Deploy Ops Manager on GCP Manually](#).

Installing PCF on GCP Manually

This topic explains how to install PCF on GCP manually.

Overview

You can install PCF on GCP with either the Pivotal Application Service (PAS) or Pivotal Container Service (PKS) runtime.

To install PCF on GCP manually, do one of the following:

- Install with PAS. See [Install Manually with PAS](#).
- Install with PKS. See [Install Manually with PKS](#).

Install Manually with PAS

To install manually with PAS, do the following:

1. Prepare to deploy Ops Manager. See [Preparing to Deploy Ops Manager on GCP Manually](#).
2. Deploy Ops Manager. See [Deploying Ops Manager on GCP Manually](#).
3. Configure BOSH Director. See [Configuring BOSH Director on GCP Manually](#).
4. (Optional). Configure a shared VPC. See [\(Optional\) Configuring a Shared VPC on GCP](#).
5. Configure PAS. See [Deploying PAS on GCP](#).

Install Manually with PKS

To install manually with PKS, do the following:

1. Prepare to deploy Ops Manager. See [Preparing to Deploy Ops Manager on GCP Manually](#).
2. Deploy Ops Manager. See [Deploying Ops Manager on GCP Manually](#).
3. Configure BOSH Director. See [Configuring BOSH Director on GCP Manually](#).
4. (Optional). Configure a shared VPC. See [\(Optional\) Configuring a Shared VPC on GCP](#).
5. Configure PKS. See [Installing PKS on GCP](#).

Preparing to Deploy Ops Manager on GCP Manually

Page last updated:

This topic describes the preparation steps required to install Ops Manager for Pivotal Cloud Foundry (PCF) on Google Cloud Platform (GCP).

Prerequisites

Before you prepare your Ops Manager installation, do the following depending on the runtime you intend to deploy:

- If you are deploying Pivotal Application Service (PAS), see [PCF on GCP Requirements](#).
- If you are deploying Pivotal Container Service (PKS), see [GCP Prerequisites and Resource Requirements](#).

Configuration and Components

This section outlines high-level infrastructure options for PCF on GCP. A PCF deployment includes Ops Manager and your chosen runtime. For example, both Ops Manager with PAS and Ops Manager with PKS are PCF deployments. For more information, review the deployment options and recommendations in [Reference Architecture for Pivotal Cloud Foundry on GCP](#).

When deploying PCF on GCP, Pivotal recommends using the following GCP components:

- [Google Cloud SQL](#) for external database services
- [NAT Gateway Instances](#) to limit the number of VMs with public IP addresses
- [Google Cloud Storage](#) for external file storage

For more information, review the different deployment options and recommendations in [Reference Architecture for Pivotal Cloud Foundry on GCP](#).

Step 1: Set up an IAM Service Account

1. From the GCP console, select **IAM & Admin**, then **Service accounts**.

2. Click **Create Service Account**:

- **Service account name:** Enter a name. For example, `bosh`.
- **Role:** Select the following roles:
 - **Service Accounts > Service Account User**
 - **Service Accounts > Service Account Token Creator**
 - **Compute Engine > Compute Instance Admin (v1)**
 - **Compute Engine > Compute Network Admin**
 - **Compute Engine > Compute Storage Admin**
 - **Storage > Storage Admin**

Note: You must scroll down in the pop-up windows to select all required roles.

The **Service Account User** role is only required if you plan to use **The Ops Manager VM Service Account** to deploy Ops Manager. For more information about **The Ops Manager VM Service Account**, see [Step 2: Google Cloud Platform Config in Configuring BOSH Director on GCP](#).

- **Service account ID:** The field automatically generates a unique ID based on the username.
- **Furnish a new private key:** Select this checkbox and JSON as the **Key type**.

Create service account

Service account name ?
bosh

Service account ID
bosh-48 @cf-sf-onboarding-env-3.iam.g...

☒ **Furnish a new private key**
Downloads a file that contains the private key. Store the file in a secure location. The private key can't be recovered if lost.

Key type
☒ **JSON**
Recommended
☐ **P12**
For backward compatibility with code using the P12 format

☐ **Enable G Suite Domain-wide Delegation**
Allows this service account to be authorized to access all resources in the domain without manual authorization on their part. [Learn more](#)

Role ?
Compute Instance Admin (v1)

Selected

- ✓ Compute Instance Admin (v1)
- ✓ Compute Network Admin
- ✓ Compute Storage Admin
- ✓ Service Account Token Creator
- ✓ Service Account User
- ✓ Storage Admin

Project

- App Engine
- BigQuery
- Billing
- Cloud IAP
- Cloud KMS
- Cloud SQL
- Cloud Security Scanner

3. Click **Create**. Your browser automatically downloads a JSON file with a private key for this account. Save this file in a secure location.

Step 2: Enable Google Cloud APIs

Ops Manager manages GCP resources using the Google Compute Engine and Cloud Resource Manager APIs. To enable these APIs, do the following:

1. Log in to the Google Developers Console at <https://console.developers.google.com>.
2. In the console, navigate to the GCP project where you want to install Ops Manager.
3. Select **API Manager > Library**.
4. Under **Google Cloud APIs**, select **Compute Engine API**.
5. On the **Google Compute Engine API** page, click **Enable**.
6. In the search field, enter `Google Cloud Resource Manager API`.
7. On the **Google Cloud Resource Manager API** page, click **Enable**.
8. To verify that the APIs have been enabled, do the following:
 - a. Log in to GCP using the IAM service account you created in [Set up an IAM Service Account](#):

```
$ gcloud auth activate-service-account --key-file JSON_KEY_FILENAME
```

- b. List your projects:

```
$ gcloud projects list
PROJECT_ID      NAME      PROJECT_NUMBER
my-project-id   my-project-name   #####
```

This command lists the projects where you enabled Google Cloud APIs.

Step 3: Create a GCP Network with Subnets

1. Log in to the [GCP console](#).
2. Navigate to the GCP project where you want to install Ops Manager.
3. Select **VPC network**, then **CREATE VPC NETWORK**.

4. In the **Name** field, enter a name of your choice for the VPC network. This name helps you identify resources for this deployment in the GCP console. Network names must be lowercase. For example, `pcf-virt-net`.

[←](#)
Create a VPC network

Name

- a. Under **Subnets**, complete the form as follows to create an infrastructure subnet for Ops Manager and NAT instances:

| | |
|-------------------------|--|
| Name | <p><code>pcf-infrastructure-subnet-GCP-REGION</code></p> <p>Example: <code>pcf-infrastructure-subnet-us-west1</code></p> |
| Region | <p>A region that supports three availability zones. For help selecting the correct region for your deployment, see the Google documentation about regions and zones.</p> |
| IP address range | <p>A CIDR ending in <code>/26</code></p> <p>Example: <code>192.168.101.0/26</code></p> |

See the following image for an example:

New subnet

Name ?

pcf-subnet-infrastructure-us-west1

Add a description

Region ?

us-west1

IP address range ?

192.168.101.0/26

Create secondary IP range

Private Google access ?

☐ On
 ☒ Off

Flow logs

☐ On
 ☒ Off

Done

Cancel

 **Note:** For deployments that do not use external IP addresses, enable **Private Google access** to allow your runtime to make API calls to Google services.

- b. Click **Add subnet** to add a second subnet for the BOSH Director and components specific to your runtime. Complete the form as follows:

| | |
|------------------|---|
| Name | pcf-RUNTIME-subnet-GCP-REGION Example: pcf-pas-subnet-us-west1 |
| Region | The same region you selected for the infrastructure subnet |
| IP address range | A CIDR ending in /22 Example: 192.168.16.0/22 |

- c. Click **Add subnet** to add a third **Subnet** with the following details:

| | |
|--------|---|
| Name | pcf-services-subnet-GCP-REGION Example: pcf-services-subnet-us-west1 |
| Region | The same region you selected for the previous subnets |
| | |

| | |
|---|--|
| IP address range | A CIDR in <input type="text" value="/22"/> |
| Example: <input type="text" value="192.168.20.0/22"/> | |

See the following image for an example:

| VPC networks + CREATE VPC NETWORK REFRESH | | | | | | | |
|---|----------|------------------------------------|--------|---------------------|---------------|----------------|------------------------|
| Name ^ | Region | Subnets | Mode | IP addresses ranges | Gateways | Firewall Rules | Global dynamic routing |
| pcf-virt-network | | 3 | Custom | | | 0 | Off |
| | us-west1 | pcf-subnet-ert-us-west1 | | 192.168.16.0/22 | 192.168.16.1 | | |
| | us-west1 | pcf-subnet-infrastructure-us-west1 | | 192.168.101.0/26 | 192.168.101.1 | | |
| | us-west1 | pcf-subnet-services-us-west1 | | 192.168.20.0/22 | 192.168.20.1 | | |

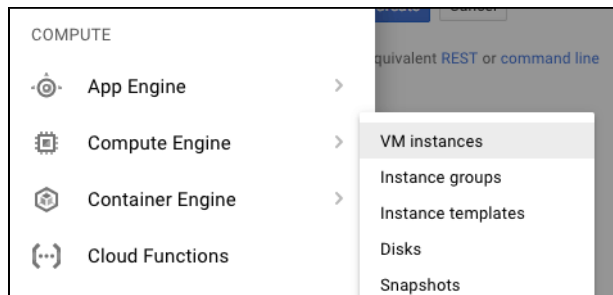

- Under **Dynamic routing mode**, leave **Regional** selected.
- Click **Create**.

Step 4: Create NAT Instances

Use NAT instances when you want to expose only a minimal number of public IP addresses.

Creating NAT instances permits internet access from cluster VMs. You might, for example, need this internet access for pulling Docker images or enabling internet access for your workloads.

For more information, see [Reference Architecture for Pivotal Cloud Foundry on GCP](#) and [GCP documentation](#).

- In the console, navigate to **Compute Engine** > **VM instances**.

- Click **CREATE INSTANCE**.

- Complete the following fields:

- Name:** Enter . This is the first, or primary, of three NAT instances you need. If you use a single AZ, you need only one NAT instance.
- Zone:** Select the first zone from your region. Example: For region , select zone .
- Machine type:** Select .
- Boot disk:** Click **Change** and select .

Create an instance

Name [?]
pcf-nat-gateway-pri

Zone [?]
us-west1-a

Machine type
4 vCPUs 15 GB memory [Customize](#)

Boot disk [?]
New 10 GB standard persistent disk
Image
Ubuntu 14.04 LTS [Change](#)

4. Expand the additional configuration fields by clicking **Management, disks, networking, SSH keys**.

Firewall [?]
Add tags and firewall rules to allow specific network traffic from the Internet

☐ Allow HTTP traffic
☐ Allow HTTPS traffic

Management, disks, networking, SSH keys

- a. In the **Startup script** field under **Automation**, enter the following text:

```
#!/bin/bash
sudo sysctl -w net.ipv4.ip_forward=1
sudo sh -c 'echo net.ipv4.ip_forward=1 >> /etc/sysctl.conf'
sudo iptables -t nat -A POSTROUTING -o eth0 -j MASQUERADE
```

Automation

Startup script (Optional)
You can choose to specify a startup script that will run when your instance boots up or restarts. Startup scripts can be used to install software and updates, and to ensure that services are running within the virtual machine. [Learn more](#)

```
#!/bin/bash
sudo sh -c 'echo 1 > /proc/sys/net/ipv4/ip_forward'
```

Management Disks **Networking** SSH Keys

Network tags [?] (Optional)
nat-traverse x pcf-nat-instance x

5. Click **Networking** to open additional network configuration fields:

- In the **Network tags** field, add the following: `nat-traverse` and `pcf-nat-instance`.
- Click on the **Networking** tab and the pencil icon to edit the **Network interface**.
- For **Network**, select `pcf-virt-net`. You created this network in [Step 1: Create a GCP Network with Subnets](#).
- For **Subnetwork**, select `pcf-infrastructure-subnet-GCP-REGION`.
- For **Primary internal IP**, select `Ephemeral (Custom)`. Enter an IP address, for example, `192.168.101.2`, in the **Custom ephemeral IP address** field. The IP address must meet the following requirements:
 - The IP address must exist in the CIDR range you set for the `pcf-infrastructure-subnet-GCP-REGION` subnet.
 - The IP address must exist in a reserved IP range set later in BOSH Director. The reserved range is typically the first `.1` through `.9` addresses in the CIDR range you set for the `pcf-infrastructure-subnet-GCP-REGION` subnet.
 - The IP address cannot be the same as the Gateway IP address set later in Ops Manager. The Gateway IP address is typically the first `.1` address in the CIDR range you set for the `pcf-infrastructure-subnet-GCP-REGION` subnet.
- For **External IP**, select `Ephemeral`.

Note: If you select a static external IP address for the NAT instance, then you can use the static IP to further secure access to your CloudSQL instances.

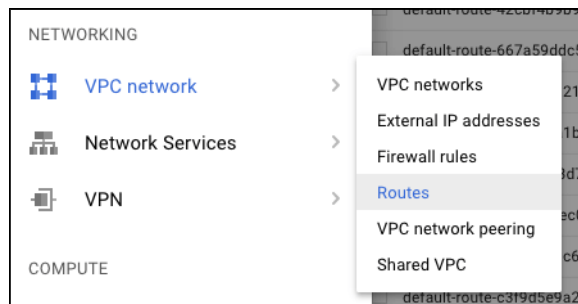

- g. Set **IP forwarding** to **On**.
- h. Click **Done**.

6. Click **Create** to finish creating the NAT instance.

7. Repeat steps 2-6 to create two additional NAT instances with the names and zones specified in the table below. The rest of the configuration remains the same.

| | | |
|------------|-------------|---|
| Instance 2 | Name | pcf-nat-gateway-sec |
| | Zone | Select the second zone from your region. Example: For region <code>us-west1</code> , select zone <code>us-west1-b</code> . |
| | Internal IP | Select Custom and enter an IP address in the Internal IP address field. Example: <code>192.168.101.3</code> . As described above, this address must in the CIDR range you set for the <code>pcf-infrastructure-subnet-GCP-REGION</code> subnet, must exist in a reserved IP range set later in BOSH Director, and cannot be the same as the Gateway IP address set later in Ops Manager. |
| Instance 3 | Name | pcf-nat-gateway-ter |
| | Zone | Select the third zone from your region. Example: For region <code>us-west1</code> , select zone <code>us-west1-c</code> . |
| | Internal IP | Select Custom and enter an IP address in the Internal IP address field. Example: <code>192.168.101.4</code> . As described above, this address must in the CIDR range you set for the <code>pcf-infrastructure-subnet-GCP-REGION</code> subnet, must exist in a reserved IP range set later in BOSH Director, and cannot be the same as the Gateway IP address set later in Ops Manager. |

Create Routes for NAT Instances

1. In the GCP console, navigate to **VPC Networks > Routes**.

2. Click **CREATE ROUTE**.

3. Complete the form as follows:

- o **Name:** `pcf-nat-pri`
- o **Network:** `pcf-virt-net`
- o **Destination IP range:** `0.0.0.0/0`
- o **Priority:** `800`
- o **Instance tags:** `pcf`
- o **Next hop:** `Specify an instance`
- o **Next hop instance:** `pcf-nat-gateway-pri`

4. Click **Create** to finish creating the route.

5. Repeat steps 2-4 to create two additional routes with the names and next hop instances specified in the table below. The rest of the configuration remains the same.

| | |
|---------|---|
| Route 2 | Name: <code>pcf-nat-sec</code> Next hop instance: <code>pcf-nat-gateway-sec</code> |
| Route 3 | Name: <code>pcf-nat-ter</code> Next hop instance: <code>pcf-nat-gateway-ter</code> |

Step 5: Create Firewall Rules for the Network

GCP lets you assign tags to VM instances and create firewall rules that apply to VMs based on their tags. For more information about tags, see [Labeling Resources](#) in the Google Cloud documentation. This step assigns tags and firewall rules to Ops Manager components and VMs that handle incoming traffic.

1. In the **Networking** > **VPC network** pane, select **Firewall rules**.
2. Apply the firewall rules in the following table:

| Firewall Rules | |
|-------------------|---|
| Rule 1 | <p>This rule allows SSH from public networks.</p> <p>Name: <code>pcf-allow-ssh</code></p> <p>Network: <code>pcf-virt-net</code></p> <p>Allowed protocols and ports: <code>tcp:22</code></p> <p>Source filter: IP ranges</p> <p>Source IP ranges: <code>0.0.0.0/0</code></p> <p>Target tags: <code>allow-ssh</code></p> |
| Rule 2 | <p>This rule allows HTTP from public networks.</p> <p>Name: <code>pcf-allow-http</code></p> <p>Network: <code>pcf-virt-net</code></p> <p>Allowed protocols and ports: <code>tcp:80</code></p> <p>Source filter: IP ranges</p> <p>Source IP ranges: <code>0.0.0.0/0</code></p> <p>Target tags: <code>allow-http</code>, <code>router</code></p> |
| Rule 3 | <p>This rule allows HTTPS from public networks.</p> <p>Name: <code>pcf-allow-https</code></p> <p>Network: <code>pcf-virt-net</code></p> <p>Allowed protocols and ports: <code>tcp:443</code></p> <p>Source filter: IP ranges</p> <p>Source IP ranges: <code>0.0.0.0/0</code></p> <p>Target tags: <code>allow-https</code>, <code>router</code></p> |
| Rule 4 | <p>This rule allows Gorouter health checks.</p> <p>Name: <code>pcf-allow-http-8080</code></p> <p>Network: <code>pcf-virt-net</code></p> <p>Allowed protocols and ports: <code>tcp:8080</code></p> <p>Source filter: IP ranges</p> <p>Source IP Ranges: <code>0.0.0.0/0</code></p> <p>Target tags: <code>router</code></p> |
| Rule 5 | <p>This rule allows communication between BOSH-deployed jobs.</p> <p>Name: <code>pcf-allow-pas-all</code></p> <p>Network: <code>pcf-virt-net</code></p> <p>Allowed protocols and ports: <code>tcp;udp;icmp</code></p> <p>Source filter: Source tags</p> <p>Target tags: <code>pcf</code>, <code>pcf-opsman</code>, <code>nat-traverse</code></p> <p>Source tags: <code>pcf</code>, <code>pcf-opsman</code>, <code>nat-traverse</code></p> |
| Rule 6 (Optional) | <p>This rule allows access to the TCP router.</p> <p>Name: <code>pcf-allow-cf-tcp</code></p> <p>Network: <code>pcf-virt-net</code></p> <p>Source filter: IP ranges</p> <p>Source IP ranges: <code>0.0.0.0/0</code></p> <p>Allowed protocols and ports: <code>tcp:1024-65535</code></p> <p>Target tags: <code>pcf-cf-tcp</code></p> |
| | <p>This rule allows access to the SSH proxy.</p> <p>Name: <code>pcf-allow-ssh-proxy</code></p> |

| | |
|-------------------|--|
| Rule 7 (Optional) | Network: <code>pcf-virt-net</code> Source filter: IP ranges Source IP ranges: <code>0.0.0.0/0</code> Allowed protocols and ports: <code>tcp:2222</code> Target tags: <code>pcf-ssh-proxy</code> , <code>diego-brain</code> |
|-------------------|--|

 **Note:** If you want your firewall rules to only permit traffic within your private network, modify the **Source IP Ranges** from the table accordingly.

3. If you are only using your GCP project to deploy Ops Manager, then you can delete the following default firewall rules:

- `default-allow-http`
- `default-allow-https`
- `default-allow-icmp`
- `default-allow-internal`
- `default-allow-rdp`
- `default-allow-ssh`

If you are deploying **PKS only**, continue to [Next Steps](#).

If you are deploying **PAS or other runtimes**, proceed to the following step.

Step 6: Create Database Instance and Databases

Create Database Instance

1. From the GCP console, select **SQL** and click **CREATE INSTANCE**.
2. Ensure **MySQL** is selected and click **Next**.
3. Under **MySQL**, select instance type **Second Generation**.
4. Click **Configure MySQL** under your choice for instance type: Development, Staging, or Production.
5. Configure the instance as follows:
 - **Instance ID:** `pcf-pas-sql`
 - **Root password:** Set a password for the root user.
 - **Region:** Select the region you specified when creating networks.
 - **Zone:** Any.
 - **Configure machine type and storage:**
 - Click **Change** and then select **db-n1-standard-2**.
 - Ensure that **Enable automatic storage increases** is selected. This allows DB storage to grow automatically when space is required.
 - **Enable auto backups and high availability:** Make the following selections:
 - Leave **Automate backups** and **Enable binary logging** selected.
 - Under **High availability**, select the **Create failover replica** checkbox.
 - **Authorize Networks:** Click **Add network** and create a network named `all` that allows traffic from `0.0.0.0/0`.

 **Note:** If you assigned static IP addresses to your NAT instances, you can instead limit access to the database instances by specifying the NAT IP addresses.

6. Click **Create**.

Create Databases

1. From the **Instances** page, select the database instance you just created.
2. Select the **Databases** tab.

3. Click **Create database** to create the following databases:

- o account
- o app_usage_service
- o autoscale
- o cddb
- o console
- o diego
- o locket
- o networkpolicyserver
- o nfsvolume
- o notifications
- o routing
- o silk
- o uaa
- o credhub

4. Select the **USERS** tab.

5. Click **Create user account** to create a unique username and password for each database you created above. For **Host name**, select **Allow any host**. You must create a total of fourteen user accounts.

 **Note:** Ensure that the networkpolicyserver database user has the **ALL PRIVILEGES** permission.

Step 7: Create Storage Buckets

1. From the GCP Console, select **Storage** > **Browser**.

2. Using **CREATE BUCKET**, create buckets with the following names. For **Default storage class**, select **Multi-Regional**:

- o pcf-buildpacks
- o pcf-droplets
- o pcf-packages
- o pcf-resources

Step 8: Create HTTP Load Balancer

Create Instance Group

1. Navigate to **Compute Engine** > **Instance groups**.

2. Click **CREATE INSTANCE GROUP**.

3. Complete the form as follows:

- o For **Name**, enter **pcf-http-lb**
- o For **Location**, select **Single-zone**.
- o For **Zone**, select the first zone from your region.
Example: For region **us-west1**, select zone **us-west1-a**.
- o Under **Group type**, select **Unmanaged instance group**.
- o For **Network**, select **pcf-virt-net**.
- o For **Subnetwork**, select the **pcf-pas-subnet-my-gcp-region** subnet that you created previously.
- o Click **Create**.

4. Create a second instance group with the following details:

- o **Name:** **pcf-http-lb**
- o **Location:** **Single-zone**
- o **Zone:** Select the second zone from your region.

Example: For region `us-west1`, select zone `us-west1-b`.

- **Group type:** Select **Unmanaged instance group**.
- **Network:** Select `pcf-virt-net`.
- **Subnetwork:** Select the `pcf-pas-subnet-my-gcp-region` subnet that you created previously.

5. Create a third instance group with the following details:

- **Name:** `pcf-http-lb`
- **Location:** **Single-zone**
- **Zone:** Select the third zone from your region.
Example: For region `us-west1`, select zone `us-west1-c`.
- **Group type:** Select **Unmanaged instance group**.
- **Network:** Select `pcf-virt-net`.
- **Subnetwork:** Select the `pcf-pas-subnet-my-gcp-region` subnet that you created previously.

Create Health Check

1. Navigate to **Compute Engine > Health checks**.

2. Click **CREATE HEALTH CHECK**.

3. Complete the form as follows:

- **Name:** `pcf-cf-public`
- **Port:** `8080`
- **Request path:** `/health`
- **Check interval:** `30`
- **Timeout:** `5`
- **Healthy threshold:** `10`
- **Unhealthy threshold:** `2`

4. Click **Create**.

Configure Back End

1. Navigate to **Network services > Load balancing**.

2. Click **CREATE LOAD BALANCER**.

3. Under **HTTP(S) Load Balancing**, click **Start configuration**.

4. For the **Name**, enter `pcf-global-pcf`.

5. Select **Backend configuration**

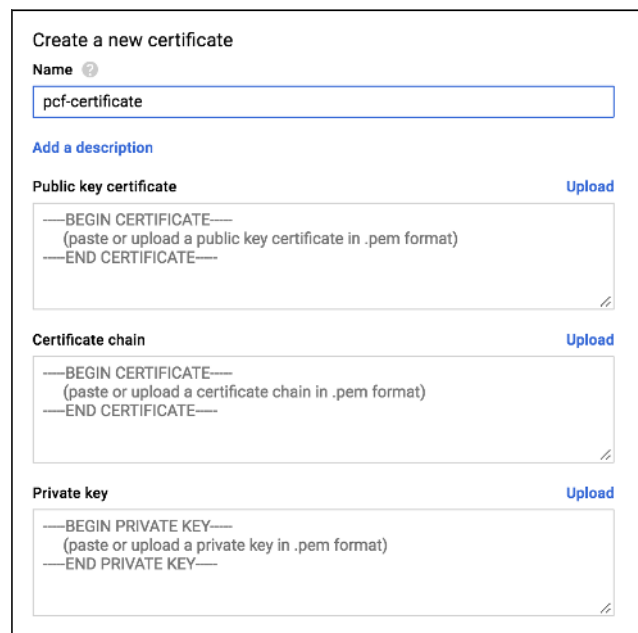

- a. From the dropdown, select **Backend services > Create a backend service**.
- b. Complete the form as follows:
 - c. **Name:** `pcf-http-lb-backend`.
 - d. **Protocol:** `HTTP`.
 - e. **Named port:** `http`.
 - f. **Timeout:** `10 seconds`.
- g. Under **Backends > New backend**, select the **Instance group** that corresponds to the first zone of the multi-zone instance group you created.
For example: `pcf-http-lb (us-west1-a)`. Click **Done**.
- h. Click **Add backend**, select the **Instance group** that corresponds to the second zone of the multi-zone instance group you created. For example:
`pcf-http-lb (us-west1-b)`. Click **Done**.
- i. Click **Add backend**, select the **Instance group** that corresponds to the third zone of the multi-zone instance group you created. For example:
`pcf-http-lb (us-west1-c)`. Click **Done**.
- j. **Health check:** Select the `pcf-cf-public` health check that you created.
- k. **Cloud CDN:** Ensure Cloud CDN is disabled.
- l. Click **Create**.

Configure Front End

1. Click **Host and path rules** to populate the default fields and a green check mark.
2. Select **Frontend configuration**, and add the following:
 - **Name:** `pcf-cf-lb-http`
 - **Protocol:** `HTTP`
 - **IP:** Perform the following steps:
 1. Select **Create IP address**.
 2. Enter a **Name** for the new static IP address and an optional description. For example, `pcf-global-pcf`.
 3. Click **Reserve**.
 - **Port:** `80`
3. If you use a trusted SSL certificate or already have a self-signed certificate, proceed to step 5.
4. If you want to use a self-signed certificate generated during [PAS network configuration](#), skip over the next step of adding the HTTPS frontend configuration until after you generate the certificate in PAS. After you generate the certificate, return to step 5 using the following guidelines:
 - Copy and paste the generated contents of the **Router SSL Termination Certificate and Private Key** fields from PAS into the public certificate and private key fields.
 - Since you are using a self-signed certificate, do not enter a value in the **Certificate Chain** field.
5. Click **Add Frontend IP and port** and add the following:

 **Note:** Skip this step if you do not have either a self-signed or trusted SSL certificate. When you configure the tile for your chosen runtime, you are given the opportunity to create a new self-signed certificate. Upon creating a certificate, you can complete the **Add Frontend IP and port** section.

- **Name:** `pcf-cf-lb-https`
- **Protocol:** `HTTPS`
- **IP address:** Select the `pcf-global-pcf` address you create for the previous **Frontend IP and Port**.
- **Port:** `443`
- Select **Create a new certificate**. The **Create a New Certificate** dialog is displayed.

- In the **Name** field, enter a name for the certificate.
- In the **Public key certificate** field, copy in the contents of your public certificate, or upload your certificate as a .pem file. If the certificate is runtime-generated, copy and paste the generated contents from the runtime's Certificate field into the Ops Manager **Public key certificate** field.
- In the **Certificate chain** field, enter or upload your certificate chain in the .pem format. If you are using a self-signed certificate, such as a PAS or PKS-generated certificate, do not enter a value in the **Certificate Chain** field.
- In the **Private key** field, copy in the contents or upload the .pem file of the private key for the certificate. If the certificate is runtime-generated, copy and paste the generated contents from the runtime's Private Key field into the Ops Manager **Private key** field.

6. Review the completed front end configuration.
7. Click **Review and finalize** to verify your configuration.

8. Click **Create**.

Step 9: Create TCP WebSockets Load Balancer

The load balancer for tailing logs with WebSockets for PCF on GCP operates on TCP port `443`.

1. From the GCP console, select **Network services > Load balancing > Create load balancer**
2. Under **TCP Load Balancing**, click **Start configuration**.

3. In the **Create a load balancer** configuration screen, make the following selections:
 - Under **Internet facing or internal only**, select **From Internet to my VMs**.
 - Under **Multiple regions or single region**, select **Single region only**.

- Under **Connection termination**, select **No (TCP)**.
4. Click **Continue**.
5. In the **New TCP load balancer** window, enter `pcf-wss-logs` in the **Name** field.
6. Click **Backend configuration** to configure the **Backend service**:

Backend configuration

Name ?

pcf-wss-logs

Region ?

us-central1

Backends ?

Select existing instance groups

Select existing instances

No instance groups in this region

Backup pool ? (Optional)

None

Failover ratio ?

10

%

Health check ?

pcf-gorouter (HTTP)

port: 8080, timeout: 5s, check interval: 5s, unhealthy threshold: 2 attempts

Session affinity ?

None

- Region: Select the region you used to create the network in [Create a GCP Network with Subnets](#).
- From the **Health check** dropdown, create a health check with the following details:
 - Name: `pcf-gorouter`
 - Port: `8080`
 - Request path: `/health`
 - Check interval: `30`
 - Timeout: `5`
 - Healthy threshold: `10`
 - Unhealthy threshold: `2` The **Backend configuration** section shows a green check mark.

7. Click **Frontend configuration** to open its configuration window and complete the fields:

- Protocol: `TCP`
- IP: Perform the following steps:
 - Select **Create IP address**.
 - For name **Name** for the new static IP address and an optional description. For example, `pcf-gorouter-wss`.
 - Click **Reserve**.

- Port: 443

Review and finalize

Backend

| TCP | :443 |

8. Click **Review and finalize** to verify your configuration.

9. Click **Create**.

Step 10: Create SSH Proxy Load Balancer

- From the GCP console, select **Network services > Load balancing > Create load balancer**
- Under **TCP Load Balancing**, click **Start configuration**.
- Under **Internet facing or internal only**, select **From Internet to my VMs**.

Create a load balancer

Please answer a few questions to help us select the right load balancing type for your application

Internet facing or internal only

Do you want to load balance traffic from the Internet to your VMs or only between VMs in your network?

☒ From Internet to my VMs
☐ Only between my VMs

Multiple regions or single region

Do you want to place the backends for your load balancer in a single region or across multiple regions?

☐ Multiple regions (or not sure yet)
☒ Single region only

Connection termination

Do you want to offload TCP or SSL processing to the Load Balancer?

☐ Yes (TCP Proxy or SSL Proxy - recommended)
☒ No (TCP)

Continue

4. Under **Connection termination**, select **No (TCP)**.

5. Click **Continue**.

6. In the **New TCP load balancer** window, enter **pcf-ssh-proxy** in the **Name** field.

7. Select **Backend configuration**, and enter the following field values:

- Region:** Select the region you used to create the network in [Create a GCP Network with Subnet](#).
- Backup pool:** None
- Failover ratio:** 10%
- Health check:** No health check

Backend configuration

Name ?

pcf-ssh-proxy

Select existing instance groups

Select existing instances

No instance groups in this region

Backup pool ? (Optional)

None

Failover ratio ?

10

%

Health check ?

No health check

Session affinity ?

None

8. Select **Frontend configuration**, and add the following:

- Protocol: `TCP`
- IP: Perform the following steps:
 1. Select **Create IP address**.
 2. Enter a **Name** for the new static IP address and an optional description. For example, `pcf-ssh-proxy`.
 3. Click **Reserve**.
- Port: `2222`

9. (Optional) Review and finalize your load balancer.

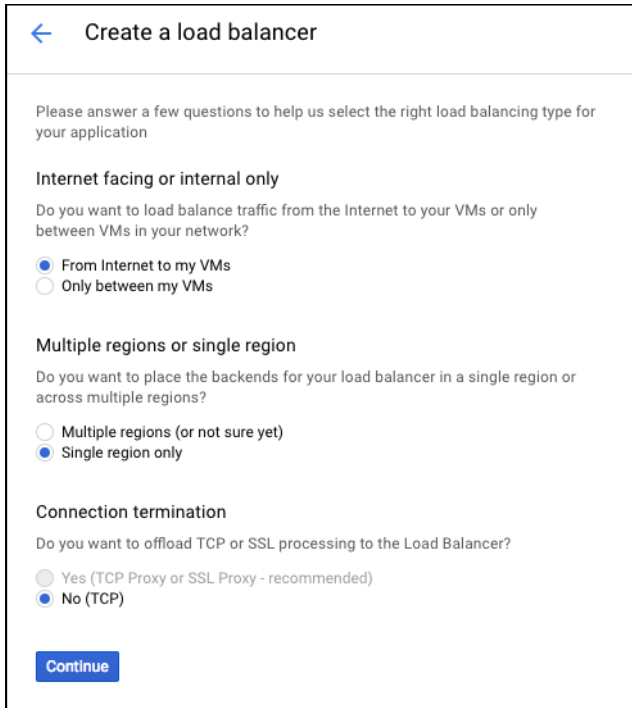

10. Click **Create**.

Step 11: Create Load Balancer for TCP Router

 **Note:** This step is optional and only required if you enable TCP routing in your deployment.

To create a load balancer for TCP routing in GCP, do the following:

1. From the GCP console, select **Network services > Load balancing > Create load balancer**
2. Under **TCP Load Balancing**, click **Start configuration**.
3. Under **Connection termination**, select **No (TCP)**. Click **Continue**.

Create a load balancer

Please answer a few questions to help us select the right load balancing type for your application

Internet facing or internal only
Do you want to load balance traffic from the Internet to your VMs or only between VMs in your network?

☒ From Internet to my VMs
☐ Only between my VMs

Multiple regions or single region
Do you want to place the backends for your load balancer in a single region or across multiple regions?

☐ Multiple regions (or not sure yet)
☒ Single region only

Connection termination
Do you want to offload TCP or SSL processing to the Load Balancer?

☐ Yes (TCP Proxy or SSL Proxy - recommended)
☒ No (TCP)

Continue

4. On the **New TCP load balancer** screen, enter a unique name for the load balancer in the **Name** field. For example, `pcf-cf-tcp-lb`.
5. Select **Backend configuration**, and enter the following field values:
 - **Region:** Select the region you used to create the network in [Create a GCP Network with Subnet](#).
 - From the **Health check** dropdown, create a health check with the following details:
 - **Name:** `pcf-tcp-lb`
 - **Port:** `80`
 - **Request path:** `/health`
 - **Check interval:** `30`
 - **Timeout:** `5`
 - **Healthy threshold:** `10`
 - **Unhealthy threshold:** `2`
 - Click **Save and continue**.

Backend configuration

Name ?

Region ?

us-central1

Backends ?

Select existing instance groups

Select existing instances

No instance groups in this region

Backup pool ? (Optional)

None

Failover ratio ?

10

%

Health check ?

pcf-tcp-lb (HTTP)

port: 80, timeout: 5s, check interval: 30s, unhealthy threshold: 2 attempts

Session affinity ?

None

6. Select **Frontend configuration**, and add the front end IP and port entry as follows:

- **Protocol:**
- **IP:** Perform the following steps:
 1. Select **Create IP address**.
 2. Enter a **Name** for the new static IP address and an optional description. For example, .
 3. Click **Reserve**.
- **Port:**

← New TCP load balancer

Name ?

pcf-cf-tcp-lb

Frontend configuration

Specify an IP address, port and protocol. This IP address is the frontend IP for your clients requests.

Protocol:TCP, IP:35, Port:1024-65535

Not saved

+ Add Frontend IP and port

7. Click **Review and finalize** to verify your configuration.

8. Click **Create**.

Step 12: Add DNS Records for Your Load Balancers

In this step you redirect queries for your domain to the IP addresses of your load balancers.

1. Locate the static IP addresses of the load balancers you created in [Step 8: Create HTTP Load Balancer](#):

- An HTTP(S) load balancer named `pcf-global-pcf`
- A TCP load balancer for WebSockets named `pcf-wss-logs`
- A TCP load balancer named `pcf-ssh-proxy`
- A TCP load balancer named `pcf-cf-tcp-lb`

Note: You can locate the static IP address of each load balancer by clicking its name under **Network services > Load balancing** in the GCP console.

2. Log in to the DNS registrar that hosts your domain. Examples of DNS registrars include Network Solutions, GoDaddy, and Register.com.

3. Create **A records** with your DNS registrar that map domain names to the public static IP addresses of the load balancers located above:

| Create and map this record... | To the IP of this load balancer | Required |
|---|---------------------------------|---|
| <code>*.sys.MY-DOMAIN</code> Example: <code>*.sys.example.com</code> | <code>pcf-global-pcf</code> | Yes |
| <code>*.apps.MY-DOMAIN</code> Example: <code>*.apps.example.com</code> | <code>pcf-global-pcf</code> | Yes |
| <code>doppler.sys.MY-DOMAIN</code> Example: <code>doppler.sys.example.com</code> | <code>pcf-wss-logs</code> | Yes |
| <code>loggregator.sys.MY-DOMAIN</code> Example: <code>loggregator.sys.example.com</code> | <code>pcf-wss-logs</code> | Yes |
| <code>ssh.sys.MY-DOMAIN</code> Example: <code>ssh.sys.example.com</code> | <code>pcf-ssh-proxy</code> | Yes, to allow SSH access to apps |
| <code>tcp.MY-DOMAIN</code> Example: <code>tcp.example.com</code> | <code>pcf-cf-tcp-lb</code> | No, only set up if you have enabled the TCP routing feature |

4. Save changes within the web interface of your DNS registrar.

5. In a terminal window, run the following `dig` command to confirm that you created your A record successfully:

```
dig SUBDOMAIN.EXAMPLE-URL.com
```

Where `SUBDOMAIN.EXAMPLE-URL` is the subdomain for your load balancer.

You should see the A record that you just created:

```
;; ANSWER SECTION:
xyz.EXAMPLE.COM. 1767 IN A 203.0.113.1
```

Next Steps

- (Optional) To prepare for deploying either a PAS or PKS tile on GCP, you can download the needed runtime tile in advance:
 - To download PAS, log in to [Pivotal Network](#), select your desired release version, and download **Pivotal Application Service**.
 - To download PKS, log in to [Pivotal Network](#), select your desired release version, and download **Pivotal Container Service**.
- After initiating the tile download, proceed to the next step, [Deploying Ops Manager on GCP Manually](#).

Deploying Ops Manager on GCP Manually

Page last updated:

This topic describes how to deploy Ops Manager for Pivotal Cloud Foundry (PCF) on Google Cloud Platform (GCP).

Before you deploy Ops Manager, see the preparation steps in [Preparing to Deploy Ops Manager on GCP Manually](#).

After you complete this procedure, follow the instructions in [Configuring BOSH Director on GCP Manually](#).

Step 1: Locate the Ops Manager Installation File

1. Log in to the [Pivotal Network](#), and click **Pivotal Cloud Foundry Operations Manager**.
2. From the **Releases** dropdown, select the release to install.
3. Select one of the following download files:
 - **Pivotal Cloud Foundry Ops Manager for GCP**
 - **Pivotal Cloud Foundry Ops Manager YAML for GCP**

When you click the download link, your browser downloads or opens the `OpsManager_VERSION_onGCP.pdf` or `OpsManager_VERSION_onGCP.yml` file.

These documents provide the GCP location of the Ops Manager `.tar.gz` installation file based on the geographic location of your installation.

4. Copy the filepath string of the Ops Manager image based on your deployment location.

Step 2: Create a Private VM Image

1. Log in to the [GCP console](#).
2. In the left navigation panel, click **Compute Engine**, and select **Images**.
3. Click **Create Image**.
4. Complete the following fields:
 - **Name:** Enter a name. For example, `om-pcf`.
 - **Encryption:** Leave **Automatic (recommended)** selected.
 - **Source:** Choose **Cloud Storage file**.
 - **Cloud Storage file:** Paste in the Google Cloud Storage filepath you copied from the PDF file in the [previous step](#).

Create an image

Name ?
om-pcf

Family (Optional) ?

Description (Optional)

Encryption ?
Automatic (recommended)

Source ?
Cloud Storage file

Cloud Storage file ?
☒ r-images/pivotal-ops-manager-20160916101000-01001000.tar.gz

Equivalent [REST](#) or [command line](#)

- Click **Create**. The file might take a few minutes to import.

Step 3: Create the Ops Manager VM Instance

- Select the checkbox for the image that you created above.

| Images [+] CREATE IMAGE ↻ REFRESH + CREATE INSTANCE ⌵ DEPRECATE 🗑 DELETE | | | | | |
|---|-------|------------|--------|---------------------------|--|
| Filter by label or name Columns ▾ Labels | | | | | |
| <input type="checkbox"/> Name | Size | Created by | Family | Creation time | |
| <input checked="" type="checkbox"/> <input checked="" type="checkbox"/> om-pcf | 50 GB | CF-Docs | | Nov 22, 2016, 10:07:54 AM | |

- Click **Create Instance**.
- In the **Create an instance form**, complete the following fields:
 - Name**: Enter a name that matches the naming conventions of your deployment.
 - Zone**: Choose a zone from the region in which you created your network.
 - Machine type**: Choose `n1-standard-2`.
 - Click **Customize** to manually configure the vCPU and memory. An Ops Manager VM instance requires the following minimum specifications:

| Machine Spec | Minimum Value |
|--------------|---------------|
| CPU | 2 vCPUs |
| Memory | 8 GB |

- Boot disk**: Click **Change**, then perform the following steps:
 - Click **Custom images** if it is not already selected.
 - Select the **Boot disk type**. If your environment has high performance needs, select **SSD**. As an example, environments used to [develop PCF tiles](#) might benefit from a higher performing Ops Manager VM boot disk. For most environments, you can select **Standard**.
 - Set the **Size (GB)** of the boot disk to the minimum or higher.

| Machine Spec | Minimum Value |
|--------------|---------------|
| Boot disk | 100 GB |

- Select the Ops Manager image you created in the previous step if it is not already selected.

- Click **Select** to save.

- Under **Identity and API access**, choose the **Service account** you created when preparing your environment during the step [Set up an IAM Service Account](#).
- **Allow HTTP traffic**: Leave this checkbox unselected.
- **Allow HTTPS traffic**: Leave this checkbox unselected.
- **Networking**: Select the **Networking** tab, and perform the following steps:
 - Under **Network interfaces**, perform the following steps:
 - Remove the `default` network interface if this interface still exists.
 - Select the network you created when preparing your environment in the [Create a GCP Network with Subnet](#) section of the *Preparing to Deploy Ops Manager on GCP Manually* topic. For example, `pcf-virt-net`.
 - Under **Subnetwork**, select the `pcf-infrastructure-subnet-GCP-REGION` subnet that you created when preparing your environment in the [Create a GCP Network with Subnet](#) section of the *Preparing to Deploy Ops Manager on GCP Manually* topic.
 - For **Primary internal IP**, select **Ephemeral (Custom)**. Enter an IP address (for example, `192.168.101.5`) in the **Custom ephemeral IP address** field. Specify the next available internal IP address located within the reserved IP range that you [configure later in BOSH Director](#). Do not use the **Gateway IP**, for example `192.168.101.1`.
 - For **External IP**, select **Create IP address**. In the next form, enter a name for the static IP. For example, `om-public-ip`. Click **Reserve**. In the **External IP** dropdown, select the static IP address you just reserved.
 - For **Network tags**, enter `pcf-opsman` and `allow-https`. These tags apply the firewall rules you created in [Create Firewall Rules for the Network](#) to the Ops Manager VM.

4. Click **Create** to deploy the new Ops Manager VM. This might take a few moments.

5. Navigate to your DNS provider, and create an entry that points a fully qualified domain name (FQDN) `opsman.MY-DOMAIN` to the `pcf-opsman` static IP address of Ops Manager that you created in a previous step.

 **Note:** In order to set up Ops Manager authentication correctly, Pivotal recommends using an FQDN to access Ops Manager. Using an ephemeral IP address to access Ops Manager can cause authentication errors upon subsequent access.

Next Steps

After you complete this procedure, follow the instructions in the [Configuring BOSH Director on GCP Manually](#) topic.

Later on, if you need to SSH into the Ops Manager VM to perform diagnostic troubleshooting, see [SSH into Ops Manager](#).

Configuring BOSH Director on GCP Manually

Page last updated:

This topic describes how to configure the BOSH Director in Ops Manager for Pivotal Cloud Foundry (PCF) on Google Cloud Platform (GCP).

 **Note:** You can also perform the procedures in this topic using the Ops Manager API. For more information, see the [Using the Ops Manager API](#) topic.

Step 1: Access Ops Manager

1. In a web browser, navigate to the fully qualified domain name (FQDN) of Ops Manager that you set up in [Deploying Ops Manager on GCP Manually](#).

 **Note:** In order to set up Ops Manager authentication correctly, Pivotal recommends using a Fully Qualified Domain Name (FQDN) to access Ops Manager. Using an ephemeral IP address to access Ops Manager can cause authentication errors upon subsequent access.

2. When Ops Manager starts for the first time, you must choose one of the following:
 - [Use an Identity Provider](#): If you use an Identity Provider, an external identity server maintains your user database.
 - [Internal Authentication](#): If you use Internal Authentication, Ops Manager maintains your user database.

Use an Identity Provider (IdP)

1. Log in to your IdP console and download the IdP metadata XML. Optionally, if your IdP supports metadata URL, you can copy the metadata URL instead of the XML.

2. Copy the IdP metadata XML or URL to the Ops Manager **Use an Identity Provider** login page.

Note: The same IdP metadata URL or XML is applied for the BOSH Director. If you use a separate IdP for BOSH, copy the metadata XML or URL from that IdP and enter it into the BOSH IdP Metadata text box in the Ops Manager login page.

3. Enter values for the fields listed below. Failure to provide values in these fields results in a `500` error.

Note: These attributes are case-sensitive.

- **SAML admin group:** Enter the name of the SAML group that contains all Ops Manager administrators.
- **SAML groups attribute:** Enter the groups attribute tag name with which you configured the SAML server.

4. Enter your **Decryption passphrase**. Read the **End User License Agreement**, and select the checkbox to accept the terms.

5. Your Ops Manager login page appears. Enter your username and password. Click **Login**.

6. Download your SAML Service Provider metadata (SAML Relying Party metadata) by navigating to the following URLs:

- **6a.** Ops Manager SAML service provider metadata: `https://OPS-MAN-FQDN:443/uaa/saml/metadata`
- **6b.** BOSH Director SAML service provider metadata: `https://BOSH-IP-ADDRESS:8443/saml/metadata`

Note: To retrieve your `BOSH-IP-ADDRESS`, navigate to the **BOSH Director** tile > **Status** tab. Record the **BOSH Director** IP address.

7. Configure your IdP with your SAML Service Provider metadata. Import the Ops Manager SAML provider metadata from Step 6a above to your IdP. If your IdP does not support importing, provide the values below.

- **Single sign on URL:** `https://OPS-MAN-FQDN:443/uaa/saml/SSO/alias/OPS-MAN-FQDN`
- **Audience URI (SP Entity ID):** `https://OP-MAN-FQDN:443/uaa`
- **Name ID:** Email Address
- SAML authentication requests are always signed

8. Import the BOSH Director SAML provider metadata from Step 6b to your IdP. If the IdP does not support an import, provide the values below.

- **Single sign on URL:** `https://BOSH-IP:8443/saml/SSO/alias/BOSH-IP`
- **Audience URI (SP Entity ID):** `https://BOSH-IP:8443`
- **Name ID:** Email Address
- SAML authentication requests are always signed

9. Return to the **BOSH Director** tile, and continue with the configuration steps below.

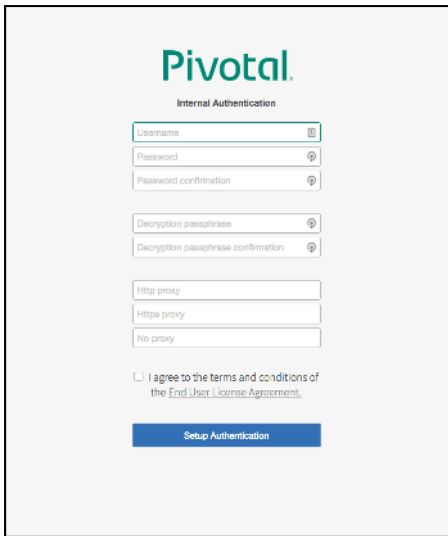

Internal Authentication

1. When redirected to the **Internal Authentication** page, do the following:

- Enter a **Username**, **Password**, and **Password confirmation** to create an Admin user.
- Enter a **Decryption passphrase** and the **Decryption passphrase confirmation**. This passphrase encrypts the Ops Manager datastore, and is not

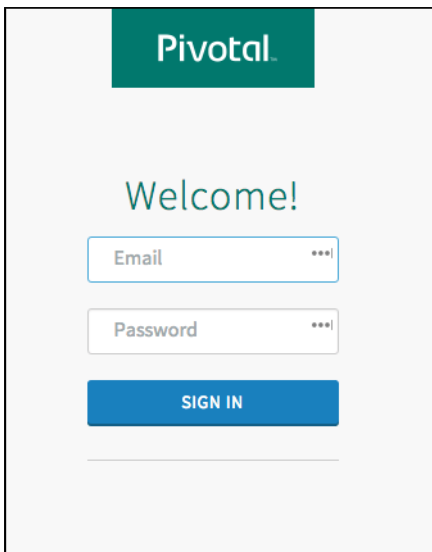

recoverable if lost.

- If you are using an **HTTP proxy** or **HTTPS proxy**, follow the instructions in the [Configuring Proxy Settings for the BOSH CPI](#) topic.
- Read the **End User License Agreement**, and select the checkbox to accept the terms.
- Click **Setup Authentication**.

The image shows the 'Pivotal Internal Authentication' setup form. It includes fields for Username, Password, Password confirmation, Decryption passphrase, and Decryption passphrase confirmation. There are also fields for Http proxy, Https proxy, and No proxy. A checkbox for 'I agree to the terms and conditions of the End User License Agreement' is present, followed by a 'Setup Authentication' button.

2. Log in to Ops Manager with the Admin username and password that you created in the previous step.

The image shows the 'Pivotal Welcome!' login form. It features a 'Pivotal' logo at the top, followed by 'Welcome!' text. Below this are input fields for 'Email' and 'Password', both with masked characters (***). A blue 'SIGN IN' button is at the bottom.

Step 2: Google Cloud Platform Config

1. Click the **Google Cloud Platform** tile within the **Installation Dashboard**.
2. Select **Google Config**. Complete the following fields:
 - **Project ID**: Enter your GCP project ID in lowercase, such as: `your-gcp-project-id`.
 - **Default Deployment Tag**: Enter the prefix that you used when creating the GCP resources for this PCF installation. For example, `pcf`.
 - Select **AuthJSON** and in the field below enter the contents of the JSON file that you downloaded in the [Set up an IAM Service Account](#) section

of the *Preparing to Deploy Ops Manager on GCP Manually* topic.

Note: As an alternative, you can select **The Ops Manager VM Service Account** option to use the service account automatically created by GCP for the Ops Manager VM. To use this option, the project-wide service account that you set up in [Set up an IAM Service Account](#) must be assigned the **Service Account Actor** role.

3. Click **Save**.

Step 3: Director Config Page

1. Select **Director Config** to open the **Director Config** page.

2. In the **NTP Servers (comma delimited)** field, enter `169.254.169.254` to designate the `metadata.google.internal` host as NTP server.

Note: The NTP server configuration only updates after VM recreation. Ensure that you select the **Recreate all VMs** checkbox if you modify the value of this field.

3. Leave the **JMX Provider IP Address** field blank.

 **Note:** Starting from PCF v2.0, BOSH-reported component metrics are available in the Loggregator Firehose by default. Therefore, if you continue to use PCF JMX Bridge for consuming them outside of the Firehose, you might receive duplicate data. To prevent this, leave the **JMX Provider IP Address** field blank. For additional guidance, see [BOSH System Metrics Available in Loggregator Firehose](#).

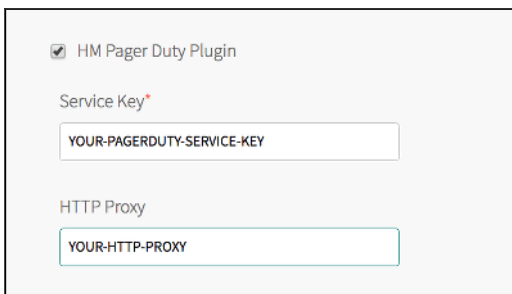

4. Leave the **Bosh HM Forwarder IP Address** field blank.

 **Note:** Starting from PCF v2.0, BOSH-reported component metrics are available in the Loggregator Firehose by default. Therefore, if you continue to use the BOSH HM Forwarder for consuming them, you might receive duplicate data. To prevent this, leave the **Bosh HM Forwarder IP Address** field blank. For additional guidance, see [BOSH System Metrics Available in Loggregator Firehose](#).

5. Select the **Enable VM Resurrector Plugin** checkbox to enable the Ops Manager Resurrector functionality and increase Pivotal Application Service (PAS) availability.
6. Select **Enable Post Deploy Scripts** to run a post-deploy script after deployment. This script allows the job to execute additional commands against a deployment.

 **Note:** You must enable post-deploy scripts to install PKS.

7. (Optional) Select **Recreate all VMs** to force BOSH to re-create all VMs on the next deploy. This process does not destroy any persistent disk data.
8. Select **Enable bosh deploy retries** for Ops Manager to retry failed BOSH operations up to five times.
9. (Optional) Disable **Allow Legacy Agents** if all of your tiles have stemcells v3468 or later. Disabling the field will allow Ops Manager to implement TLS secure communications.
10. (Optional) Select **Keep Unreachable Director VMs** if you want to preserve BOSH Director VMs after a failed deployment for troubleshooting purposes.
11. (Optional) Select **HM Pager Duty Plugin** to enable Health Monitor integration with PagerDuty.

- **Service Key:** Enter your API service key from PagerDuty.
- **HTTP Proxy:** Enter an HTTP proxy for use with PagerDuty.

☒ **HM Email Plugin**

Host*

Port*

Domain*

From*

Recipients*

Username

Password

☒ **Enable TLS**

12. (Optional) Select **HM Email Plugin** to enable Health Monitor integration with email.

- **Host:** Enter your email hostname.
- **Port:** Enter your email port number.
- **Domain:** Enter your domain.
- **From:** Enter the address for the sender.
- **Recipients:** Enter comma-separated addresses of intended recipients.
- **Username:** Enter the username for your email server.
- **Password:** Enter the password for your email server.
- **Enable TLS:** Select this checkbox to enable Transport Layer Security.

13. For **CredHub Encryption Provider**, you can choose whether BOSH CredHub stores its encryption key internally on the BOSH Director and CredHub VM, or in an external hardware security module (HSM). The HSM option is more secure.

Before configuring an HSM encryption provider in the **Director Config** pane, you must follow the procedures and collect information described in [Preparing CredHub HSMs for Configuration](#).

Note: After you deploy Ops Manager with an HSM encryption provider, you cannot change BOSH CredHub to store encryption keys internally.

CredHub Encryption Provider

☒ Internal
 ☐ Luna HSM

Encryption Key Name*

Provider Partition*

Provider Partition Password*

Provider Client Certificate*

Provider Client Certificate Private Key*

HSM Host Address*

HSM Port Address*

Partition Serial Number*

HSM Certificate*

- **Internal:** Select this option for internal CredHub key storage. This option is selected by default and requires no additional configuration.
- **Luna HSM:** Select this option to use a SafeNet Luna HSM as your permanent CredHub encryption provider, and fill in the following fields:
 1. **Encryption Key Name:** Any name to identify the key that the HSM uses to encrypt and decrypt the CredHub data. Changing this key name after you deploy Ops Manager can cause service downtime.
 2. **Provider Partition:** The partition that stores your encryption key. Changing this partition after you deploy Ops Manager could cause service downtime. For this value and the ones below, use values gathered in [Preparing CredHub HSMs for Configuration](#).
 3. **Provider Partition Password**
 4. **Provider Client Certificate:** The certificate that validates the identity of the HSM when CredHub connects as a client.
 5. **Provider Client Certificate Private Key**
 6. **HSM Host Address**
 7. **HSM Port Address:** If you do not know your port address, enter `1792`.
 8. **Partition Serial Number**
 9. **HSM Certificate:** The certificate that the HSM presents to CredHub to establish a two-way mTLS connection.

14. Select a **Blobstore Location** to either configure the blobstore as an internal server or an external endpoint. Because the internal server is unscalable and less secure, Pivotal recommends that you configure an external blobstore.

 **Note:** After you deploy Ops Manager, you cannot change the blobstore location.

Blobstore Location

☒ Internal

☐ S3 Compatible Blobstore

S3 Endpoint*

Bucket Name*

Access Key*

Secret Key*

☒ V2 Signature

☐ V4 Signature

Region*

☐ GCS Blobstore

Bucket Name*

Storage Class*

Regional

Service Account Key*

- o **Internal:** Select this option to use an internal blobstore. Ops Manager creates a new VM for blob storage. No additional configuration is required.
- o **S3 Compatible Blobstore:** Select this option to use an external S3-compatible endpoint. Follow the procedures in [Sign up for Amazon S3](#) and [Creating a Bucket](#) in the AWS documentation. When you have created an S3 bucket, complete the following steps:
 1. **S3 Endpoint:** Navigate to the [Regions and Endpoints](#) topic in the AWS documentation.
 - a. Locate the endpoint for your region in the **Amazon Simple Storage Service (S3)** table and construct a URL using your region's endpoint. For example, if you are using the `us-west-2` region, the URL you create would be `https://s3-us-west-2.amazonaws.com`. Enter this URL into the **S3 Endpoint** field.
 - b. On a command line, run `ssh ubuntu@OPS-MANAGER-FQDN` to SSH into the Ops Manager VM. Replace `OPS-MANAGER-FQDN` with the fully qualified domain name of Ops Manager.
 - c. Copy the custom public CA certificate you used to sign the S3 endpoint into `/etc/ssl/certs` on the Ops Manager VM.
 - d. On the Ops Manager VM, run `sudo update-ca-certificates -f -v` to import the custom CA certificate into the Ops Manager VM truststore.

 **Note:** You must also add this custom CA certificate into the **Trusted Certificates** field in the **Security** page. See [Security Page](#) for instructions.

2. **Bucket Name:** Enter the name of the S3 bucket.
3. **Access Key** and **Secret Key:** Enter the keys you generated when creating your S3 bucket.
4. Select **V2 Signature** or **V4 Signature**. If you select **V4 Signature**, enter your **Region**.

 **Note:** AWS recommends using Signature Version 4. For more information about AWS S3 Signatures, see [Authenticating Requests](#) in the AWS documentation.

- **Enable TLS:** Select this checkbox to enable TLS.

 **Note:** If you are using Linux stemcells, make sure you have configured [Linux stemcell v3586.16 or later](#) for all tiles before enabling TLS.

 **Note:** If you are using PAS for Windows 2016, make sure you have configured [Windows stemcell v1709.10 or later](#) for all tiles before enabling TLS.

- **GCS Blobstore:** Select this option to use an external Google Cloud Storage (GCS) endpoint. To create a GCS bucket, follow the procedures in [Creating Storage Buckets](#) in the GCS documentation. When you have created a GCS bucket, complete the following steps:
 1. **Bucket Name:** Enter the name of your GCS bucket.
 2. **Storage Class:** Select the storage class for your GCS bucket. See [Storage Classes](#) in the GCP documentation for more information.
 3. **Service Account Key:** Enter the contents of the JSON file that you downloaded in the [Set up an IAM Service Account](#) section of *Preparing to Deploy Ops Manager on GCP Manually*.

15. For **Database Location**, if you configured an external MySQL database such as Cloud SQL, select **External MySQL Database** and complete the fields below. Otherwise, select **Internal**. For more information about creating a Cloud SQL instance, see [Quickstart for Cloud SQL for MySQL](#) in the Google Cloud documentation.

- **Host:** Enter the value of your host.
- **Port:** Enter your port number. For example, .
- **Username:** Enter your username.
- **Password:** Enter your password.
- **Database:** Enter your database name.

In addition, if you selected the **Enable TLS for Director Database** checkbox, you can fill out the following optional fields:

- **Enable TLS:** Selecting this checkbox enables TLS communication between the BOSH Director and the database.
- **TLS CA:** Enter the Certificate Authority for the TLS Certificate.
- **TLS Certificate:** Enter the client certificate for mutual TLS connections to the database.
- **TLS Private Key:** Enter the client private key for mutual TLS connections to the database.
- **Advanced DB Connection Options:** If you would like to provide additional options for the database, use this field to provide a JSON-formatted options string.

16. (Optional) Modify the **Director Workers** value, which sets the number of workers available to execute Director tasks. This field defaults to .
17. (Optional) **Max Threads** sets the maximum number of threads that the BOSH Director can run simultaneously. Pivotal recommends that you leave the field blank to use the default value, unless doing so results in rate limiting or errors on your IaaS.
18. (Optional) To add a custom URL for your BOSH Director, enter a valid hostname in **Director Hostname**. You can also use this field to configure [a load balancer in front of your BOSH Director](#).

 **warning:** In Ops Manager v2.2.7 and earlier, if you change the **Director Hostname** after your initial deployment, VMs become unavailable. This causes downtime for your environment. To restore VM availability, enable **Recreate All VMs** and redeploy. This issue is resolved in [Ops Manager v2.2.8](#) and later.

Director Workers

Max Threads

Director Hostname

19. (Optional) Enter your list of comma-separated **Excluded Recursors** to declare which IP addresses and ports should not be used by the DNS server.
20. (Optional) To disable BOSH DNS, select the **Disable BOSH DNS server for troubleshooting purposes** checkbox. For more information about the BOSH DNS service discovery mechanism, see [BOSH DNS Enabled by Default](#) in the Ops Manager v2.2 Release Notes.

 **Note:** Disabling BOSH DNS affects [Step 5: Create Networks Page](#) below when you configure your network DNS.

 **Breaking Change:** Do not disable BOSH DNS without consulting Pivotal Support.

 **Note:** If you are deploying PKS, do not disable BOSH DNS. If PAS and PKS are running on the same instance of Ops Manager, you cannot use the opt-out feature of BOSH DNS for your PAS without breaking PKS. If you want to opt out of BOSH DNS in your PAS deployment, install the tile on a separate instance of Ops Manager.

21. (Optional) To set a custom banner that users see when logging in to the Director using SSH, enter text in the **Custom SSH Banner** field.

☐ Disable BOSH DNS server for troubleshooting purposes

Custom SSH Banner

22. (Optional) Enter your comma-separated custom **Identification Tags**. For example, `iaas:foundation1, hello:world`. You can use the tags to identify your foundation when viewing VMs or disks from your IaaS.
23. Click **Save**.

Step 4: Create Availability Zones Page

 **Note:** Pivotal recommends at least three availability zones for a highly available installation.

- For configuring a PAS deployment with multiple availability zones, see [Reference Architecture for Pivotal Cloud Foundry on GCP](#).
- For PKS best practices for distributing workloads across multiple availability zones and clusters, see [Maintaining Workload Uptime](#).

1. Select **Create Availability Zones**.

1. Click **Add**.

2. For **Google Availability Zone**:

- Enter one of the zones that you associated to the backend service instance groups of the HTTP(S) Load Balancer. For example, if you are using

the `us-central1` region and selected `us-central1-a` as one of the zones for your HTTP(S) Load Balancer instance groups, enter `us-central1-a`.

- Click **Add**.
- Repeat the above step for all the availability zones that you associated to instance groups in [Preparing to Deploy Ops Manager on GCP Manually](#).

- Click **Save**.

3. Repeat the above step for all the availability zones you are using in your deployment. When you are done, click **Save**.

Step 5: Create Networks Page

- Select **Create Networks**.
- Make sure **Enable ICMP checks** is not selected. GCP routers do not respond to ICMP pings.
- Click **Add Network**. Create the three networks described in the tables below.

Note: To use a shared VPC network, enter the shared VPC host project name before the network name in the format `VPC-PROJECT-NAME/NETWORK-NAME/SUBNET-NAME/REGION-NAME`. For example, `vpc-project/opsmgr/central/us-central1`. For more information, see [Configuring a Shared VPC on GCP](#).

If you disabled BOSH DNS for a PAS installation, enter `8.8.8.8` into the ****DNS Servers**** field of the PAS tile. For more information, see step 29g in the *Configure Networking* section of the [Deploying PAS on GCP](#) topic.

Infrastructure Network

| | |
|---------------------|---|
| Network Name | <code>infrastructure</code> |
| Google Network Name | Enter the name of the infrastructure network that you created in the Create a GCP Network with Subnets step of <i>Preparing to Deploy Ops Manager on GCP Manually</i> . The format is: <code>pcf-virt-net/pcf-infrastructure-subnet-MY-REGION/MY-GCP-REGION</code> |
| CIDR | Enter the name of the CIDR ending in <code>/26</code> that you used when you created the infrastructure subnet in GCP. Example: <code>192.168.101.0/26</code> |
| Reserved IP Ranges | Enter the first <code>.1</code> through <code>.9</code> addresses from the CIDR. For example, if the CIDR is <code>192.168.101.0/26</code> , enter the range <code>192.168.101.1-192.168.101.9</code> . |
| DNS | <code>169.254.169.254</code> |
| Gateway | Enter the first <code>.1</code> address from the CIDR. For example, if the CIDR is <code>192.168.101.0/26</code> , enter <code>192.168.101.1</code> . |
| Availability Zones | Select all three availability zones. |

Runtime Network

| | |
|---------------------|--|
| Name | Enter the name of the runtime that you intend to deploy in this environment. For example, <code>pas</code> or <code>pks</code> . |
| Google Network Name | Enter the name of the runtime network that you created when you prepared your GCP environment. The format is: <code>pcf-virt-net/pcf-RUNTIME-subnet-MY-REGION/MY-GCP-REGION</code> |
| CIDR | Enter the name of the CIDR ending in <code>/22</code> that you used when you created the runtime subnet in GCP. Example: <code>192.168.16.0/22</code> |
| Reserved IP Ranges | Enter the first <code>.1</code> through <code>.9</code> addresses from the CIDR. For example, if the CIDR is <code>192.168.16.0/22</code> , enter the range <code>192.168.16.1-192.168.16.9</code> . |
| DNS | <code>169.254.169.254</code> |
| Gateway | Enter the first <code>.1</code> address from the CIDR. For example, if the CIDR is <code>192.168.16.0/22</code> , enter <code>192.168.16.1</code> . |
| Availability Zones | Select all three availability zones. |

Services Network

| | |
|---------------------|--|
| Network Name | <code>services</code> |
| Google Network Name | Enter the name of the services network that you created when you prepared your GCP environment. The format is: <code>pcf-virt-net/pcf-services-subnet-MY-REGION/MY-GCP-REGION</code> |
| CIDR | Enter the name of the CIDR ending in <code>/22</code> that you used when you created the services subnet in GCP. Example: <code>192.168.20.0/22</code> |
| Reserved IP Ranges | Enter the first <code>.1</code> through <code>.9</code> addresses from the CIDR. For example, if the CIDR is <code>192.168.20.0/22</code> , enter the range <code>192.168.20.1-192.168.20.9</code> . |
| DNS | <code>169.254.169.254</code> |
| Gateway | Enter the first <code>.1</code> address from the CIDR. For example, if the CIDR is <code>192.168.16.0/22</code> , enter <code>192.168.16.1</code> . |
| Availability Zones | Select all three availability zones. |

 **Note:** After you deploy Ops Manager, you add subnets with overlapping Availability Zones to expand your network. For more information about configuring additional subnets, see [Expanding Your Network with Additional Subnets](#).

 **Note:** Ensure `169.254.169.254`, the IP address of the `metadata.google.internal` metadata server, is always specified at the beginning of this step's DNS resolver lists.

Step 6: Assign AZs and Networks Page

1. Select **Assign AZs and Networks**.
2. Use the dropdown to select a **Singleton Availability Zone**. The BOSH Director installs in this Availability Zone.
3. Under **Network**, select the `infrastructure` network for your BOSH Director.
4. Click **Save**.

Step 7: Security Page

Security

Trusted Certificates

-----BEGIN CERTIFICATE-----
THXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX
XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX
XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX
XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX
XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX

These certificates enable BOSH-deployed components to trust a custom root certificate.

Generate VM passwords or use single password for all VMs

☒ Generate passwords

☐ Use default BOSH password

Save

1. Select **Security**.
2. In **Trusted Certificates**, enter your custom certificate authority (CA) certificates to insert into your organization's certificate trust chain. This feature enables all BOSH-deployed components in your deployment to trust custom root certificates.

To enter multiple certificates, paste your certificates one after the other. For example, format your certificates like the following:

```

-----BEGIN CERTIFICATE-----
ABCEDEFGH12345678ABCEDEFGH12345678ABCEDEFGH12345678AB
EFGH12345678ABCEDEFGH12345678ABCEDEFGH12345678ABCEDEF
GH12345678ABCEDEFGH12345678ABCEDEFGH12345678...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
BCDEFGH12345678ABCEDEFGH12345678ABCEDEFGH12345678ABB
EFGH12345678ABCEDEFGH12345678ABCEDEFGH12345678ABCEDEF
GH12345678ABCEDEFGH12345678ABCEDEFGH12345678...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
CDEFGH12345678ABCEDEFGH12345678ABCEDEFGH12345678ABBB
EFGH12345678ABCEDEFGH12345678ABCEDEFGH12345678ABCEDEF
GH12345678ABCEDEFGH12345678ABCEDEFGH12345678...
-----END CERTIFICATE-----

```

 Note: If you want to use Docker Registries for running app instances in Docker containers, enter the certificate for your private Docker Registry in this field. See [Using Docker Registries](#) for more information on running app instances in PAS using Docker Registries.

3. Choose **Generate passwords** or **Use default BOSH password**. Pivotal recommends that you use the **Generate passwords** option for greater security.
4. Click **Save**. To view your saved Director password, click the **Credentials** tab.

Step 8: Syslog Page

1. Select **Syslog**.

Syslog

Do you want to configure Syslog for Bosh Director?

☐ No
 ☒ Yes

Address*

The address or host for the syslog server

Port*

Transport Protocol*

TCP

⌵

☐ Enable TLS

Permitted Peer*

SSL Certificate*

Save

- (Optional) Select **Yes** to send BOSH Director system logs to a remote server.
- In the **Address** field, enter the IP address or DNS name for the remote server.
- In the **Port** field, enter the port number that the remote server listens on.
- In the **Transport Protocol** dropdown menu, select **TCP**, **UDP**, or **REL**. This selection determines which transport protocol is used to send the logs to the remote server.
- (Optional) Pivotal strongly recommends that you enable TLS encryption when forwarding logs as they may contain sensitive information. For example, these logs may contain cloud provider credentials. To enable TLS, perform the following steps.
 - In the **Permitted Peer** field, enter either the name or SHA1 fingerprint of the remote peer.
 - In the **SSL Certificate** field, enter the SSL certificate for the remote server.
- Click **Save**.

Step 9: Resource Config Page

- Select **Resource Config**.
- Ensure that the **Internet Connected** checkboxes are not selected for any jobs. The checkbox gives VMs a public IP address that enables outbound

internet access. In [Preparing to Deploy Ops Manager on GCP Manually](#), you provisioned a Network Address Translation (NAT) box to provide internet connectivity to your VMs. For more information about using NAT in GCP, see the [GCP documentation](#).

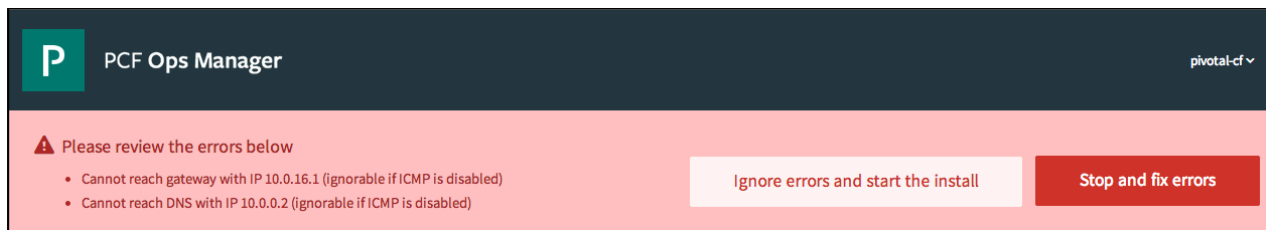

Note: If you install PAS for Windows, provision your **Master Compilation Job** with at least 100 GB of disk space.

Step 10: (Optional) Add Custom VM Extensions

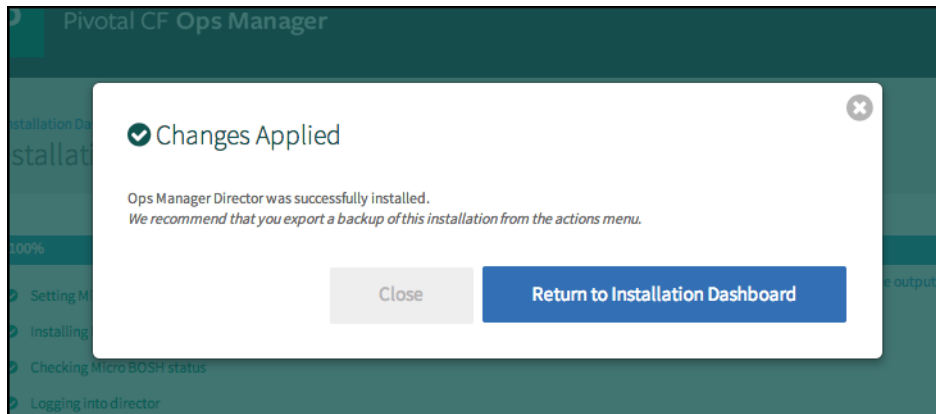

Use the Ops Manager API to add custom properties to your VMs such as associated security groups and load balancers. For more information, see [Managing Custom VM Extensions](#).

Step 11: Complete the BOSH Director Installation

1. Click the **Installation Dashboard** link to return to the Installation Dashboard.
2. Click **Apply Changes**. If the following ICMP error message appears, return to the [Network Config](#) screen, and ensure you have deselected the **Enable ICMP Checks** box. Then click **Apply Changes** again.

3. BOSH Director installs. This might take a few moments. When the installation process successfully completes, the **Changes Applied** window appears.

Next Steps

After you complete this procedure, follow the instructions for the runtime you intend to install.

- To deploy PAS, see [Deploying PAS on GCP](#).
- To prepare to deploy PKS, see [Installing PKS on GCP](#).

Deploying PAS on GCP

Page last updated:

This topic describes how to install and configure Pivotal Application Service (PAS) on Google Cloud Platform (GCP).

Before beginning this procedure, ensure that you have successfully completed the [Configuring BOSH Director on GCP](#) topic.

Note: If you plan to [install the PCF IPsec add-on](#), you must do so before installing any other tiles. Pivotal recommends installing IPsec immediately after Ops Manager, and before installing the PAS tile.

Step 1: Download the PAS Tile

1. If you have not already downloaded PAS, log in to [Pivotal Network](#), and click PAS.
2. From the **Releases** drop-down, select the release to install and choose one of the following:
 - a. Click PAS to download the PAS `.pivotal` file.
 - b. Click **PCF Small Footprint Runtime** to download the Small Footprint Runtime `.pivotal` file. For more information, see [Getting Started with Small Footprint Runtime](#).

Step 2: Add PAS to Ops Manager

1. Navigate to the Pivotal Cloud Foundry Operations Manager Installation Dashboard.
2. Click **Import a Product** to add the PAS tile to Ops Manager. This may take a while depending on your connection speed.

Tip: After you import a tile to Ops Manager, you can view the latest available version of that tile in the Installation Dashboard by enabling the Pivotal Network API. For more information, refer to the [Adding and Deleting Products](#) topic.

3. On the left, click the plus icon next to the imported PAS product to add it to the Installation Dashboard.
4. Click the newly added PAS tile in the Installation Dashboard.

Step 3: Assign Availability Zones and Networks

1. Select **Assign AZ and Networks**. These are the Availability Zones that you created in [Step 4: Create Availability Zones Page](#) of the *Configuring BOSH Director on GCP* topic.
2. Select the first Availability Zone under **Place singleton jobs**. Ops Manager runs any job with a single instance in this Availability Zone.
3. Select all Availability Zones under **Balance other jobs**. Ops Manager balances instances of jobs with more than one instance across the Availability Zones that you specify.

Note: For production deployments, Pivotal recommends at least three Availability Zones for a highly available installation of PAS.

4. From the **Network** dropdown, choose the network you created in [Step 5: Create Networks Page](#) of the *Configuring BOSH Director on GCP Manually* topic.

- Click **Save**.

Step 4: Add DNS Records for Your Load Balancers

In this step, you redirect queries for your domain to the IP addresses of your load balancers.

- Locate the static IP addresses of the load balancers you created in [Preparing to Deploy Ops Manager on GCP Manually](#):
 - An HTTP(S) load balancer named `MY-PCF-global-pcf`
 - A TCP load balancer for WebSockets named `MY-PCF-wss-logs`
 - A TCP load balancer for SSH access to applications named `MY-PCF-ssh-proxy`
 - A TCP load balancer for the TCP router named `MY-PCF-cf-tcp-lb` if you plan on enabling the TCP routing feature

 **Note:** You can locate the static IP address of each load balancer by clicking its name under **Networks > Load balancing** in the GCP Console.

- Log in to the DNS registrar that hosts your domain. Examples of DNS registrars include Network Solutions, GoDaddy, and Register.com.
- Create **A records** with your DNS registrar that map domain names to the public static IP addresses of the load balancers located above:

| If your DNS entry is: | Set to the public IP of this load balancer: | Required | Example |
|------------------------------|---|---|--------------------------------|
| *.YOURSYSTEMDOMAIN | <code>MY-PCF-global-pcf</code> | Yes | *.system.example.com |
| *.YOURAPPSDOMAIN | <code>MY-PCF-global-pcf</code> | Yes | *.apps.example.com |
| doppler.YOURSYSTEMDOMAIN | <code>MY-PCF-wss-logs</code> | Yes | doppler.system.example.com |
| loggregator.YOURSYSTEMDOMAIN | <code>MY-PCF-wss-logs</code> | Yes | loggregator.system.example.com |
| ssh.YOURSYSTEMDOMAIN | <code>MY-PCF-ssh-proxy</code> | Yes, to allow SSH access to apps | ssh.system.example.com |
| tcp.YOURDOMAIN | <code>MY-PCF-cf-tcp-lb</code> | No, only set up if you have enabled the TCP routing feature | tcp.example.com |

- Save changes within the web interface of your DNS registrar.
- In a terminal window, run the following `dig` command to confirm that you created your A record successfully:

```
dig xyz.EXAMPLE.COM
```

You should see the A record that you just created:

```
:: ANSWER SECTION:
xyz.EXAMPLE.COM. 1767 IN A 203.0.113.1
```

 **Note:** You **must** complete this step before proceeding to Cloud Controller configuration. A difficult-to-resolve problem can occur if the wildcard domain is improperly cached before the A record is registered.

Step 5: Configure Domains

- Select **Domains**.

Application Service hosts applications at subdomains under its apps domain and assigns system components to subdomains under its system domain. You need to configure a wildcard DNS for both the apps domain and system domain. The two domains can be the same, although this is not recommended.

System Domain *

Apps Domain *

Save

2. Enter the system and application domains that you created in [Step 12: Add DNS Records for Your Load Balancers](#) of the *Preparing GCP* topic.
 - The **System Domain** defines your target when you push apps to PAS.
 - The **Apps Domain** defines where PAS serves your apps.

Note: Pivotal recommends that you use the same domain name but different subdomain names for your system and app domains. For example, use `system.example.com` for your system domain, and `apps.example.com` for your apps domain.

3. Click **Save**.

Step 6: Configure Networking

1. Select **Networking**.
2. Leave the **Router IPs**, **SSH Proxy IPs**, **HAProxy IPs**, and **TCP Router IPs** fields blank. You do not need to complete these fields when deploying PCF to GCP.

Note: You specify load balancers in the **Resource Config** section of PAS later on in the installation process. See the [Configure Load Balancers](#) section of this topic for more information.

3. Under **Certificates and Private Key for HAProxy and Router**, you must provide at least one **Certificate and Private Key** name and certificate keypair for HAProxy and Gorouter. The HAProxy and Gorouter are enabled to receive TLS communication by default. You can configure multiple certificates for HAProxy and Gorouter.
 - a. Click the **Add** button to add a name for the certificate chain and its private keypair. This certificate is the default used by Gorouter and HAProxy.

Certificates and Private Keys for HAProxy and Router

Add

▼ example-cert

Name *

example-cert

A human-readable name describing the use of this certificate.

Certificate and Private Key for HAProxy and Router *

-----BEGIN CERTIFICATE-----

MIIE...

-----END CERTIFICATE-----

-----BEGIN RSA PRIVATE KEY-----

MIIE...

-----END RSA PRIVATE KEY-----

Generate RSA Certificate

▼ example-cert-2

Name *

example-cert-2

Certificate and Private Key for HAProxy and Router *

-----BEGIN CERTIFICATE-----

MIIE...

-----END CERTIFICATE-----

-----BEGIN RSA PRIVATE KEY-----

MIIE...

-----END RSA PRIVATE KEY-----

You can either provide a certificate signed by a Certificate Authority (CA) or click on the **Generate RSA Certificate** link to generate a self-signed

certificate in Ops Manager.

- b. If you want to configure multiple certificates for HAProxy and Gorouter, click the **Add** button and fill in the appropriate fields for each additional certificate keypair.

For details about generating certificates in Ops Manager for your wildcard system domains, see the [Providing a Certificate for Your SSL/TLS Termination Point](#) topic.

Note: If you configured Ops Manager Front End without a certificate, you can use this new certificate to complete Ops Manager configuration. To configure your Ops Manager Front End certificate, see *Configure Front End* in [Preparing to Deploy Ops Manager on GCP Manually](#).

Note: Ensure that you add any certificates that you generate in this pane to your infrastructure load balancer.

4. (Optional) When validating client requests using mutual TLS, the Gorouter trusts multiple certificate authorities (CAs) by default. If you want to configure the Gorouter and HAProxy to trust additional CAs, enter your CA certificates under **Certificate Authorities Trusted by Router and HAProxy**. All CA certificates should be appended together into a single collection of PEM-encoded entries.

Certificate Authorities Trusted by Router and HAProxy

In addition to well-known, public CAs, and those trusted via the BOSH trusted certificates collection, these certificates can be used to validate the certificates from incoming client requests. All CA certificates should be appended together into a single collection of PEM-encoded entries.

5. In the **Minimum version of TLS supported by HAProxy and Router** field, select the minimum version of TLS to use in HAProxy and Gorouter communications. HAProxy and Gorouter use TLS v1.2 by default. If you need to accommodate clients that use an older version of TLS, select a lower minimum version. For a list of TLS ciphers supported by the Gorouter, see [Securing Traffic into Cloud Foundry](#).

Minimum version of TLS supported by HAProxy and Router*

☐ TLSv1.0
☐ TLSv1.1
☒ TLSv1.2

6. Configure **Logging of Client IPs in CF Router**. The **Log client IPs** option is set by default. To comply with the General Data Protection Regulation (GDPR), select one of the following options to disable logging of client IP addresses:

- o If your load balancer exposes its own source IP address, disable logging of the `X-Forwarded-For` HTTP header only.
- o If your load balancer exposes the source IP of the originating client, disable logging of both the source IP address and the `X-Forwarded-For` HTTP header.

Logging of Client IPs in CF Router*

☒ Log client IPs
☐ Disable logging of X-Forwarded-For header only
☐ Disable logging of both source IP and X-Forwarded-For header

To comply with GDPR, select one of the options to disable logging of client IPs. If the source IP exposed by your load balancer is its own, choose to disable logging of XFF header only. If the source IP exposed by your load balancer is that of the downstream client, choose to disable logging of the source IP also.

7. Under **Configure support for the X-Forwarded-Client-Cert header**, configure PCF handles `x-forwarded-client-cert` (XFCC) HTTP headers based on where TLS is terminated for the first time in your deployment.

Configure support for the X-Forwarded-Client-Cert header. This header can be used by applications to verify the requester via mutual TLS. The option you should select depends upon where you will be terminating the TLS connection for the first time. *

- ☒ TLS terminated for the first time at infrastructure load balancer
- ☐ TLS terminated for the first time at HAProxy
- ☐ TLS terminated for the first time at the Router

The following table

indicates which option to choose based on your deployment layout.

| If your deployment is configured as follows: | Then select the following option: | Additional notes: |
|--|--|--|
| <ul style="list-style-type: none"> The Load Balancer is terminating TLS, and Load balancer is configured to put the client certificate from a mutual authentication TLS handshake into the X-Forwarded-Client-Cert HTTP header | TLS terminated for the first time at infrastructure load balancer (default). | Both HAProxy and the Gorouter forward the XFCC header when included in the request. |
| <ul style="list-style-type: none"> The Load Balancer is configured to pass through the TLS handshake via TCP to the instances of HAProxy, and HAProxy instance count is > 0 | TLS terminated for the first time at HAProxy. | <p>HAProxy sets the XFCC header with the client certificate received in the TLS handshake. The Gorouter forwards the header.</p> <p>Breaking Change: In the Router behavior for Client Certificates field, you cannot select the Router does not request client certificates option.</p> |
| <ul style="list-style-type: none"> The Load Balancer is configured to pass through the TLS handshake via TCP to instances of the Gorouter | TLS terminated for the first time at the Gorouter. | <p>The Gorouter strips the XFCC header if it is included in the request and forwards the client certificate received in the TLS handshake in a new XFCC header.</p> <p>If you have deployed instances of HAProxy, app traffic bypasses those instances in this configuration. If you have also configured your load balancer to route requests for ssh directly to the Diego Brain, consider reducing HAProxy instances to 0.</p> <p>Breaking Change: In the Router behavior for Client Certificates field, you cannot select the Router does not request client certificates option.</p> |

For a description of the behavior of each configuration option, see [Forward Client Certificate to Applications](#).

- To configure HAProxy to handle client certificates, select one of the following options in the **HAProxy behavior for Client Certificate Validation** field.

HAProxy behavior for Client Certificate Validation *

- ☒ HAProxy does not request client certificates.
- ☐ HAProxy requests but does not require client certificates. This option is necessary if you want to enable mTLS for applications and TLS is terminated for the first time at HAProxy

- HAProxy does not request client certificates.** This option requires mutual authentication, which makes it incompatible with XFCC option **TLS terminated for the first time at HAProxy**. HAProxy does not request client certificates, so the client does not provide them and no validation occurs. This is the default configuration.
- HAProxy requests but does not require client certificates.** The HAProxy requests client certificates in TLS handshakes, validates them when presented, but does not require them.

Warning: Upon upgrade, PAS will fail to receive requests if your load balancer is configured to present a client certificate in the TLS handshake with HAProxy but HAProxy has not been configured with the certificate authority used to sign it. To mitigate this issue, select **HAProxy does not request client certificates** in the **Networking** pane or configure the HAProxy with the appropriate CA.

- To configure Gorouter behavior for handling client certificates, select one of the following options in the **Router behavior for Client Certificate Validation** field.

Router behavior for Client Certificate Validation*

- ☐ Router does not request client certificates. This option is incompatible with XFCC options "TLS terminated for the first time at HAProxy" and "TLS terminated for the first time at the Router" because these options require mutual authentication.
- ☒ Router requests but does not require client certificates.
- ☐ Router requires client certificates.

- o **Router does not request client certificates.** This option is incompatible with the XFCC configuration options **TLS terminated for the first time at HAProxy** and **TLS terminated for the first time at the Router** in PAS because these options require mutual authentication. As client certificates are not requested, client will not provide them, and thus validation of client certificates will not occur.
- o **Router requests but does not require client certificates.** The Gorouter requests client certificates in TLS handshakes, validates them when presented, but does not require them. This is the default configuration.
- o **Router requires client certificates.** The Gorouter validates that the client certificate is signed by a Certificate Authority that the Gorouter trusts. If the Gorouter cannot validate the client certificate, the TLS handshake fails.

⚠ warning: Requests to the platform will fail upon upgrade if your load balancer is configured with client certificates and the Gorouter does not have the certificate authority. To mitigate this issue, select **Router does not request client certificates** for **Router behavior for Client Certificate Validation** in the **Networking** pane.

10. In the **TLS Cipher Suites for Router** field, review the TLS cipher suites for TLS handshakes between Gorouter and front-end clients such as load balancers or HAProxy. The default value for this field is `ECDHE-RSA-AES128-GCM-SHA256:TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384`. If you want to modify the default configuration, use an ordered, colon-delimited list of Golang-supported TLS cipher suites in the OpenSSL format. Operators should verify that the ciphers are supported by any clients or front-end components that will initiate TLS handshakes with Gorouter. For a list of TLS ciphers supported by Gorouter, see [Securing Traffic into Cloud Foundry](#).

TLS Cipher Suites for Router *

`ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384`

Verify that every client participating in TLS handshakes with Gorouter has at least one cipher suite in common with Gorouter.

💡 Note: Specify cipher suites that are supported by the versions configured in the **Minimum version of TLS supported by HAProxy and Router** field.

11. In the **TLS Cipher Suites for HAProxy** field, review the TLS cipher suites for TLS handshakes between HAProxy and its clients such as load balancers and Gorouter. The default value for this field is the following:
`DHE-RSA-AES128-GCM-SHA256:DHE-RSA-AES256-GCM-SHA384:ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384` If you want to modify the default configuration, use an ordered, colon-delimited list of TLS cipher suites in the OpenSSL format. Operators should verify that the ciphers are supported by any clients or front-end components that will initiate TLS handshakes with HAProxy.

TLS Cipher Suites for HAProxy *

`DHE-RSA-AES128-GCM-SHA256:DHE-RSA-AES256-GCM-SHA384:ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384`

Verify that every client participating in TLS handshakes with HAProxy has at least one cipher suite in common with HAProxy.

 **Note:** Specify cipher suites that are supported by the versions configured in the **Minimum version of TLS supported by HAProxy and Router** field.

12. Under **HAProxy forwards requests to Router over TLS**, select **Enable** or **Disable** based on your deployment layout.

HAProxy forwards requests to Router over TLS. When enabled, HAProxy will forward all requests to the Router over TLS. HAProxy will use the CA provided to verify the certificates provided by the Router. *

☒ Enable

Certificate Authority for HAProxy Backend *

You need to provide a certificate authority for the certificate and key provided in the "Certificate and Private Key for HAProxy and Router" field. HAProxy will verify those certificates using this CA when establishing a connection. If you generated that certificate and key using the "Generate RSA Certificate" feature, then your CA is the Ops Manager CA, and can be found by visiting the "/api/v0/certificate_authorities" API endpoint.

☐ Disable

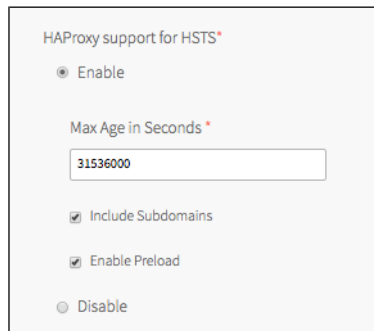

- **Enable HAProxy forwarding of requests to Router over TLS**

| | |
|--------------------------------------|---|
| If you want to: | Encrypt communication between HAProxy and the Gorouter |
| Then configure the following: | <ol style="list-style-type: none"> 1. Leave Enable selected. 2. In the Certificate Authority for HAProxy Backend field, specify the Certificate Authority (CA) that signed the certificate you configured in the Certificate and Private Key for HAProxy and Router field. <div>  Note: If you used the Generate RSA Certificate link to generate a self-signed certificate, then the CA to specify is the Ops Manager CA, which you can locate at the <code>/api/v0/certificate_authorities</code> endpoint in the Ops Manager API. </div> <ol style="list-style-type: none"> 3. Make sure that Gorouter and HAProxy have TLS cipher suites in common in the TLS Cipher Suites for Router and TLS Cipher Suites for HAProxy fields. |
| See also: | <ul style="list-style-type: none"> ◦ Terminating SSL/TLS at the Load Balancer and Gorouter ◦ Providing a Certificate for Your SSL/TLS Termination Point ◦ Using the Ops Manager API |

- **Disable HAProxy forwarding of requests to Router over TLS**

| | |
|--------------------------------------|---|
| If you want to: | Use non-encrypted communication between HAProxy and Gorouter, or you are not using HAProxy |
| Then configure the following: | <ol style="list-style-type: none"> 1. Select Disable. 2. If you are not using HAProxy, set the number of HAProxy job instances to <code>0</code> on the Resource Config page. See Disable Unused Resources. |
| See also: | <ul style="list-style-type: none"> ◦ Terminating SSL/TLS at the Gorouter Only ◦ Terminating SSL/TLS at the Load Balancer Only |

13. If you want to force browsers to use HTTPS when making requests to HAProxy, select **Enable** in the **HAProxy support for HSTS** field and complete

HAProxy support for HSTS*

☒ Enable

Max Age in Seconds*

31536000

☒ Include Subdomains

☒ Enable Preload

☐ Disable

the following optional configuration steps:

- a. (Optional) **Enter a Max Age in Seconds** for the HSTS request. By default, the age is set to one year. HAProxy will force HTTPS requests from browsers for the duration of this setting.
- b. (Optional) Select the **Include Subdomains** checkbox to force browsers to use HTTPS requests for all component subdomains.
- c. (Optional) Select the **Enable Preload** checkbox to force instances of Google Chrome, Firefox, and Safari that access your HAProxy to refer to their built-in lists of known hosts that require HTTPS, of which HAProxy is one. This ensures that the first contact a browser has with your HAProxy is an HTTPS request, even if the browser has not yet received an HSTS header from HAProxy.

14. If you are not using SSL encryption or if you are using self-signed certificates, select **Disable SSL certificate verification for this environment**. Selecting this checkbox also disables SSL verification for route services.

 **Note:** For production deployments, Pivotal does not recommend disabling SSL certificate verification.

15. (Optional) If you want HAProxy or the Gorouter to reject any HTTP (non-encrypted) traffic, select the **Disable HTTP on HAProxy and Gorouter** checkbox. When selected, HAProxy and Gorouter will not listen on port 80.

☐ Disable HTTP on HAProxy and Gorouter

16. (Optional) Select the **Disable insecure cookies on the Router** checkbox to set the secure flag for cookies generated by the router.
17. (Optional) To disable the addition of Zipkin tracing headers on the Gorouter, deselect the **Enable Zipkin tracing headers on the router** checkbox. Zipkin tracing headers are enabled by default. For more information about using Zipkin trace logging headers, see [Zipkin Tracing in HTTP Headers](#).
18. (Optional) To stop the Router from writing access logs to local disk, deselect the **Enable Router to write access logs locally** checkbox. You should consider disabling this checkbox for high traffic deployments since logs may not be rotated fast enough and can fill up the disk.
19. By default, the PAS routers handle traffic for applications deployed to an isolation segment created by the PCF Isolation Segment tile. To configure the PAS routers to reject requests for applications within isolation segments, select the **Routers reject requests for Isolation Segments** checkbox.

☐ Routers reject requests for Isolation Segments

Do not enable this option without deploying

routers for each isolation segment. See the following topics for more information:

- [Installing PCF Isolation Segment](#)
- [Sharding Routers for Isolation Segments](#).

20. (Optional) By default, Gorouter support for the PROXY protocol is disabled. To enable the PROXY protocol, select **Enable support for PROXY protocol in CF Router**. When enabled, client-side load balancers that terminate TLS but do not support HTTP can pass along information from the originating client. Enabling this option may impact Gorouter performance. For more information about enabling the PROXY protocol in Gorouter, see the *HTTP Header Forwarding* sections in the [Securing Traffic in Cloud Foundry](#) topic.
21. In the **Choose whether to enable route services** section, choose either **Enable route services** or **Disable route services**. Route services are a class of [marketplace services](#) that perform filtering or content transformation on application requests and responses. See the [Route Services](#) topic for details.
 - a. If you enabled route services, you can also configure the **Bypass security checks for route service lookup** field. Pivotal recommends that you do not enable this field because it has potential security concerns. However, you may need to enable it if your load balancer requires mutual TLS from clients. For more information, see [Configuring Route Service Lookup](#).
22. (Optional) If you want to limit the number of app connections to the backend, enter a value in the **Max Connections Per Backend** field. You can use this field to prevent a poorly behaving app from all the connections and impacting other apps.

To choose a value for this field, review the peak concurrent connections received by instances of the most popular apps in your deployment. You can determine the number of concurrent connections for an app from the `httpStartStop` event metrics emitted for each app request.

If your deployment uses PCF Metrics, you can also obtain this peak concurrent connection information from [Network Metrics](#). The default value is

Max Connections Per Backend *

0

500

23. Under **Enable Keepalive Connections for Router**, select **Enable** or **Disable**. Keepalive connections are enabled by default. For more information, see [Keepalive Connections](#) in *HTTP Routing*.

Enable Keepalive Connections for Router*

☒ Enable
 ☐ Disable

24. (Optional) To accommodate larger uploads over connections with high latency, increase the number of seconds in the **Router Timeout to Backends** field.
25. (Optional) Use the **Frontend Idle Timeout for Gorouter and HAProxy** field to help prevent connections from your load balancer to Gorouter or HAProxy from being closed prematurely. The value you enter sets the duration, in seconds, that Gorouter or HAProxy maintains an idle open connection from a load balancer that supports keep-alive.

In general, set the value higher than your load balancer's backend idle timeout to avoid the race condition where the load balancer sends a request before it discovers that Gorouter or HAProxy has closed the connection.

See the following table for specific guidance and exceptions to this rule:

| IaaS | Guidance |
|-------|---|
| AWS | AWS ELB has a default timeout of 60 seconds, so Pivotal recommends a value greater than <code>60</code> . |
| Azure | By default, Azure load balancer times out at 240 seconds without sending a TCP RST to clients, so as an exception, Pivotal recommends a value lower than <code>240</code> to force the load balancer to send the TCP RST. |
| GCP | GCP has a default timeout of 600 seconds. For GCP HTTP load balancers, Pivotal recommends a value greater than <code>600</code> . For GCP TCP load balancers, Pivotal recommends a value less than <code>600</code> to force the load balancer to send a TCP RST. |
| Other | Set the timeout value to be greater than that of the load balancer's backend idle timeout. |

 **Note:** Do not set a frontend idle timeout lower than six seconds.

26. (Optional) Increase the value of **Load Balancer Unhealthy Threshold** to specify the amount of time, in seconds, that the router continues to accept connections before shutting down. During this period, healthchecks may report the router as unhealthy, which causes load balancers to failover to other routers. Set this value to an amount greater than or equal to the maximum time it takes your load balancer to consider a router instance unhealthy, given contiguous failed healthchecks.
27. (Optional) Modify the value of **Load Balancer Healthy Threshold**. This field specifies the amount of time, in seconds, to wait until declaring the Router instance started. This allows an external load balancer time to register the Router instance as healthy.

Load Balancer Unhealthy Threshold *

20

Load Balancer Healthy Threshold *

20

28. (Optional) If app developers in your organization want certain HTTP headers to appear in their app logs with information from the Gorouter, specify them in the **HTTP Headers to Log** field. For example, to support app developers that deploy Spring apps to PCF, you can enter [Spring-specific HTTP headers](#).

HTTP Headers to Log

29. If you expect requests larger than the default maximum of 16 Kbytes, enter a new value (in bytes) for **HAProxy Request Max Buffer Size**. You may need to do this, for example, to support apps that embed a large cookie or query string values in headers.

30. If your PCF deployment uses HAProxy and you want it to receive traffic only from specific sources, use the following fields:

- **HAProxy Protected Domains:** Enter a comma-separated list of domains to protect from unknown source requests.
- **HAProxy Trusted CIDRs:** Optionally, enter a space-separated list of CIDRs to limit which IP addresses from the **Protected Domains** can send traffic to PCF.

HAProxy Protected Domains

A comma-separated list of domains to protect from requests from unknown sources. Use this property in conjunction with "Trusted CIDRs" to protect these domains from requests from unknown sources.

HAProxy Trusted CIDRs

31. The **Loggregator Port** defaults to **443** if left blank. Enter a new value to override the default.

Container Network Interface Plugin*

32. For **Container Network Interface Plugin**, ensure **Silk** is selected and review the following fields:

Note: The **External** option exists to support NSX-T integration for vSphere deployments.

- (Optional) You can change the value in the **Applications Network Maximum Transmission Unit (MTU)** field. Pivotal recommends setting the MTU value for your application network to **1454**. Some configurations, such as networks that use GRE tunnels, may require a smaller MTU value.
- (Optional) Enter an IP range for the overlay network in the **Overlay Subnet** box. If you do not set a custom range, Ops Manager uses **10.255.0.0/16**.

warning: The overlay network IP range must not conflict with any other IP addresses in your network.

- Enter a UDP port number in the **VXLAN Tunnel Endpoint Port** box. If you do not set a custom port, Ops Manager uses 4789.
- For **Denied logging interval**, set the per-second rate limit for packets blocked by either a container-specific [networking policy](#) or by [Application Security Group](#) rules applied across the space, org, or deployment. This field defaults to **1**.
- For **UDP logging interval**, set the per-second rate limit for UDP packets sent and received. This field defaults to **100**.
- To enable logging for app traffic, select **Log traffic for all accepted/denied application packets**. See [Manage Logging for Container-to-Container Networking](#) for more information.
- For **DNS Servers**, enter **8.8.8.8** only if you have BOSH disabled. Otherwise, you cannot use this field to override the DNS servers used in containers.

Note: If you do not want to configure your DNS servers with **8.8.8.8**, contact [Pivotal Support](#).

33. For **DNS Search Domains**, enter DNS search domains for your containers as a comma-separated list. DNS on your containers appends these names to its host names, to resolve them into full domain names.

DNS Search Domains

example.com, myapps.com

DNS search domains to be used in containers. A comma-separated list can be specified.

34. For **Database Connection Timeout**, set the connection timeout for clients of the policy server and silk databases. The default value is **120**. You may need to increase this value if your deployment experiences timeout issues related to Container-to-Container Networking.

35. (Optional) TCP Routing is disabled by default. You should enable this feature if your DNS sends TCP traffic through a load balancer rather than directly to a TCP router. To enable TCP routing:

- a. Select **Enable TCP Routing**.
- b. For **TCP Routing Ports**, enter a single port or a range of ports for the load balancer to forward to. These are the same ports that you configured in the [Pre-Deployment Steps](#) of the *Enabling TCP Routing* topic.
 - To support multiple TCP routes, Pivotal recommends allocating multiple ports.
 - To allocate a list of ports rather than a range:
 1. Enter a single port in the **TCP Routing Ports** field.
 2. After deploying PAS, follow the directions in [Configuring a List of TCP Routing Ports](#) to add TCP routing ports using the cf CLI.

Enable TCP requests to your apps via specific ports on the TCP router. You will want to configure a load balancer to forward these TCP requests to the TCP routers. If you do not have a load balancer, then you can also send traffic directly to the TCP router.*

☐ Select this option if you prefer to enable TCP Routing at a later time
 ☒ Enable TCP Routing

TCP Routing Ports (one-time configuration, if you want to update this value you can via the CF CLI) *

- c. For GCP, you also need to specify the name of a GCP TCP load balancer in the **LOAD BALANCER** column of TCP Router job of the **Resource Config** screen. You configure this later on in PAS. See [Configure Load Balancers](#) section of this topic.

36. (Optional) To disable TCP routing, click **Select this option if you prefer to enable TCP Routing at a later time** For more information, see the [Configuring TCP Routing in PAS](#) [↗](#) topic.

37. Click **Save**.

Step 7: Configure Application Containers

1. Select **Application Containers**.

Enable microservice frameworks, private Docker registries, and other services that support your applications at a container level.

- ☒ Enable Custom Buildpacks
- ☒ Allow SSH access to app containers
- ☒ Enable SSH when an app is created
- ☒ Enable the GrootFS container image plugin for Garden RunC

☐ Router uses TLS to verify application identity

Private Docker Insecure Registry Whitelist

10.10.10.10:8888,example.com:8888

Docker Images Disk-Cleanup Scheduling on Cell VMs*

- ☐ Never clean up Cell disk-space
- ☐ Routinely clean up Cell disk-space
- ☒ Clean up disk-space once threshold is reached

Threshold of Disk-Used (MB) (min: 1) *

10240

- The **Enable Custom Buildpacks** checkbox governs the ability to pass a custom buildpack URL to the `-b` option of the `cf push` command. By default, this ability is enabled, letting developers use custom buildpacks when deploying apps. Disable this option by disabling the checkbox. For more information about custom buildpacks, refer to the [buildpacks](#) section of the PCF documentation.
- The **Allow SSH access to app containers** checkbox controls SSH access to application instances. Enable the checkbox to permit SSH access across your deployment, and disable it to prevent all SSH access. See the [Application SSH Overview](#) topic for information about SSH access permissions at the space and app scope.
- If you want to enable SSH access for new apps by default in spaces that allow SSH, select **Enable SSH when an app is created**. If you deselect the checkbox, developers can still enable SSH after pushing their apps by running `cf enable-ssh APP-NAME`.
- If you want to disable the Garden Root filesystem (GrootFS), deselect the **Enable the GrootFS container image plugin for Garden RunC** checkbox. Pivotal recommends using this plugin, so it is enabled by default. However, some external components are sensitive to dependencies with filesystems such as GrootFS. If you experience issues, such as antivirus or firewall compatibility problems, deselect the checkbox to roll back to the plugin that is built into Garden RunC. For more information about GrootFS, see [Component: Garden](#) and [Container Mechanics](#).

 **Note:** If you modify this setting, Pivotal recommends recreating all VMs in the BOSH Director config. You can do this by selecting the **Recreate all VMs** checkbox in the **Director Config** pane of the BOSH Director tile before you redeploy.

- To enable Gorouter to verify app identity using TLS, select the **Router uses TLS to verify application identity** checkbox.

Verifying app identity using TLS enables encryption between router and app containers and guards against misrouting during control plane failures. For more information about Gorouter route consistency modes, see [Preventing Misrouting](#) in *HTTP Routing*.

 **warning:** TLS routing requires an additional 32 MB of RAM capacity on Diego cells per app instance. It also requires additional CPU capacity on Diego cells. If the total amount of Diego cell memory available is less than 32 MB times the number of running app instances, scale your Diego cells before configuring the Gorouter with TLS.

 **Warning:** You may see an increase of memory and CPU usage for your Gorouters after enabling TLS routing. If the total amount of memory and CPU usage of the Gorouters in your environment are close to the size limit, scale your Gorouters before enabling TLS routing.

7. You can configure Pivotal Application Service (PAS) to run app instances in Docker containers by supplying their IP address ranges in the **Private Docker Insecure Registry Whitelist** textbox. See the [Using Docker Registries](#) topic for more information.
8. Select your preference for **Docker Images Disk-Cleanup Scheduling on Cell VMs**. If you choose **Clean up disk-space once threshold is reached**, enter a **Threshold of Disk-Used** in megabytes. For more information about the configuration options and how to configure a threshold, see [Configuring Docker Images Disk-Cleanup Scheduling](#).
9. Enter a number in the **Max Inflight Container Starts** textbox. This number configures the maximum number of started instances across the Diego cells in your deployment. For more information about this feature, see [Setting a Maximum Number of Started Containers](#).
10. Under **Enabling NFSv3 volume services**, select **Enable** or **Disable**. NFS volume services allow application developers to bind existing NFS volumes to their applications for shared file access. For more information, see the [Enabling NFS Volume Services](#) topic.

Note: In a clean install, NFSv3 volume services is enabled by default. In an upgrade, NFSv3 volume services is set to the same setting as it was in the previous deployment.

11. (Optional) To configure LDAP for NFSv3 volume services, do the following:

Enabling NFSv3 volume services will allow application developers to bind existing NFS volumes to their applications for shared file access. *

☒ Enable

LDAP Service Account User

LDAP Service Account Password

LDAP Server Host

LDAP Server Port

LDAP User Fully-Qualified Domain Name

☐ Disable

Format of timestamps in Diego logs*

☒ RFC3339 timestamps (e.g. 2018-02-09T00:54:13.479724884Z)

☐ Seconds since the Unix epoch (e.g. 1518137653.479724884)

Save

- For **LDAP Service Account User**, enter the username of the service account in LDAP that will manage volume services.
- For **LDAP Service Account Password**, enter the password for the service account.
- For **LDAP Server Host**, enter the hostname or IP address of the LDAP server.
- For **LDAP Server Port**, enter the LDAP server port number. If you do not specify a port number, Ops Manager uses 389.
- For **LDAP User Fully-Qualified Domain Name**, enter the fully qualified path to the LDAP service account. For example, if you have a service account named `volume-services` that belongs to organizational units (OU) named `service-accounts` and `my-company`, and your domain is named `domain`, the fully qualified path looks like the following:

```
CN=volume-services,OU=service-accounts,OU=my-company,DC=domain,DC=com
```

12. By default, PAS manages container images using the [GrootFS](#) plugin for Garden-runC. If you experience issues with GrootFS, you can disable the plugin and use the image plugin built into Garden-runC.

13. Select the **Format of timestamps in Diego logs**, either **RFC3339 timestamps** or **Seconds since the Unix epoch**. Fresh PAS v2.2 installations default to **RFC3339 timestamps**, while upgrades to PAS v2.2 from previous versions default to **Seconds since the Unix epoch**.
14. You can optionally modify the **Default health check timeout**. The value configured for this field is the amount of time allowed to elapse between starting up an app and the first healthy response from the app. If the health check does not receive a healthy response within the configured timeout, then the app is declared unhealthy. The default timeout is seconds and the maximum configurable timeout is seconds.
15. Click **Save**.

Step 8: Configure Application Developer Controls

1. Select **Application Developer Controls**.

Configure restrictions and default settings for applications pushed to Application Service.

Maximum File Upload Size (MB) (min: 1024, max: 2048) *

Default App Memory (MB) (min: 64, max: 2048) *

Default App Memory Quota per Org (MB) (min: 10240, max: 102400) *

Maximum Disk Quota per App (MB) (min: 512, max: 20480) *

Default Disk Quota per App (MB) (min: 512, max: 20480) *

Default Service Instances Quota per Org (min: 0, max: 1000) *

Staging Timeout (Seconds) *

☐ Allow Space Developers to manage network policies

☒ Enable Service Discovery for Apps

Save

2. Enter the **Maximum File Upload Size (MB)**. This is the maximum size of an application upload.
3. Enter the **Default App Memory (MB)**. This is the amount of RAM allocated by default to a newly pushed application if no value is specified with the cf CLI.
4. Enter the **Default App Memory Quota per Org**. This is the default memory limit for all applications in an org. The specified limit only applies to the first installation of PAS. After the initial installation, operators can use the cf CLI to change the default value.

5. Enter the **Maximum Disk Quota per App (MB)**. This is the maximum amount of disk allowed per application.

Note: If you allow developers to push large applications, PAS may have trouble placing them on Cells. Additionally, in the event of a system upgrade or an outage that causes a rolling deploy, larger applications may not successfully re-deploy if there is insufficient disk capacity. Monitor your deployment to ensure your Cells have sufficient disk to run your applications.

6. Enter the **Default Disk Quota per App (MB)**. This is the amount of disk allocated by default to a newly pushed application if no value is specified with the cf CLI.
7. Enter the **Default Service Instances Quota per Org**. The specified limit only applies to the first installation of PAS. After the initial installation, operators can use the cf CLI to change the default value .
8. Enter the **Staging Timeout (Seconds)**. When you stage an application droplet with the Cloud Controller, the server times out after the number of seconds you specify in this field.
9. Select the **Allow Space Developers to manage network policies** checkbox to permit developers to manage their own network policies for their applications.
10. The **Enable Service Discovery for Apps** checkbox, which enables service discovery between applications, is enabled by default. To disable this feature, clear this checkbox. For more information about application service discovery, see the [App Service Discovery](#) section of the *Understanding Container-to-Container Networking* topic.
11. Click **Save**.

Step 9: Review Application Security Groups

Setting appropriate [Application Security Groups](#) is critical for a secure deployment. Type ☐ in the box to acknowledge that once the Pivotal Application Service (PAS) deployment completes, you will review and set the appropriate application security groups. See [Restricting App Access to Internal PCF Components](#) for instructions.

Setting appropriate Application Security Groups that control application network policy is the responsibility of the Elastic Runtime administration team. Please refer to the Application Security Groups topic in the Pivotal Cloud Foundry documentation for more detail on completing this activity after the Elastic Runtime deployment completes.

Type X to acknowledge that you understand this message *

Save

Step 10: Configure UAA

1. Select **UAA**.
2. (Optional) Under **JWT Issuer URI**, enter the URI that UAA uses as the issuer when generating tokens.

JWT Issuer URI

3. Under **SAML Service Provider Credentials**, enter a certificate and private key to be used by UAA as a SAML Service Provider for signing outgoing SAML authentication requests. You can provide an existing certificate and private key from your trusted Certificate Authority or generate a self-signed certificate. The following domain must be associated with the certificate: `*.login.YOUR-SYSTEM-DOMAIN`.

Note: The Pivotal Single Sign-On Service and Pivotal Spring Cloud Services tiles require the `*.login.YOUR-SYSTEM-DOMAIN`.

- If the private key specified under **Service Provider Credentials** is password-protected, enter the password under **SAML Service Provider Key**

SAML Service Provider Credentials *

-----BEGIN CERTIFICATE-----
M
U
H
M
-----END CERTIFICATE-----

[Change](#)

SAML Service Provider Key Password

Secret

Password.

- (Optional) To override the default value, enter a custom SAML Entity ID in the **SAML Entity ID Override** field. By default, the SAML Entity ID is `http://login.YOUR-SYSTEM-DOMAIN` where `YOUR-SYSTEM-DOMAIN` is set in the **Domains > System Domain** field.
- For **Signature Algorithm**, choose an algorithm from the dropdown menu to use for signed requests and assertions. The default value is `SHA256`.
- (Optional) In the **Apps Manager Access Token Lifetime**, **Apps Manager Refresh Token Lifetime**, **Cloud Foundry CLI Access Token Lifetime**, and **Cloud Foundry CLI Refresh Token Lifetime** fields, change the lifetimes of tokens granted for Apps Manager and Cloud Foundry Command Line

The screenshot shows a configuration panel for the UAA (User Access and Authentication) service. It contains several input fields for setting various lifetimes and timeouts, each followed by a red asterisk indicating it is a required field. The fields and their values are:

- Apps Manager Access Token Lifetime (in seconds) *: 1209600
- Apps Manager Refresh Token Lifetime (in seconds) *: 1209600
- Cloud Foundry CLI Access Token Lifetime (in seconds) *: 7200
- Cloud Foundry CLI Refresh Token Lifetime (in seconds) *: 1209600
- Global Login Session Max Timeout (in seconds) *: 1800
- Global Login Session Idle Timeout (in seconds) *: 1800
- Customize Username Label (on login page) *: Email
- Customize Password Label (on login page) *: Password
- Proxy IPs Regular Expression *: 10\.\d{1,3}\.\d{1,3}\.\d{1,3}192\.168\.\d{1,3}

At the bottom of the panel is a blue "Save" button.

Interface (cf CLI) login access and refresh. Most deployments use the defaults.

8. (Optional) In the **Global Login Session Max Timeout** and **Global Login Session Idle Timeout** fields, change the maximum number of seconds before a global login times out. These fields apply to the following:
 - **Default zone sessions:** Sessions in Apps Manager, PCF Metrics, and other web UIs that use the UAA default zones
 - **Identity zone sessions:** Sessions in apps that use a UAA identity zone, such as a Single Sign-On service plan
9. (Optional) Customize the text prompts used for username and password from the cf CLI and Apps Manager login popup by entering values for **Customize Username Label (on login page)** and **Customize Password Label (on login page)**.
10. (Optional) The **Proxy IPs Regular Expression** field contains a pipe-delimited set of regular expressions that UAA considers to be reverse proxy IP addresses. UAA respects the `x-forwarded-for` and `x-forwarded-proto` headers coming from IP addresses that match these regular expressions. To configure UAA to respond properly to Router or HAProxy requests coming from a public IP address, append a regular expression or regular expressions to match the public IP address.
11. You can configure UAA to use an internal MySQL database provided with PCF, or you can configure an external database provider. Follow the procedures in either the [Internal Database Configuration](#) or the [External Database Configuration](#) section below.

 **Note:** For GCP installations, Pivotal recommends selecting **External** and using Google Cloud SQL.

 **Note:** If you are performing an upgrade, do not modify your existing internal database configuration or you may lose data. You must migrate your existing data before changing the configuration. See [Upgrading Pivotal Cloud Foundry](#) for additional upgrade information, and contact [Pivotal Support](#) for help.

Internal Database Configuration

When you configure the UAA to use an internal MySQL database, it uses the type of database selected in the **Databases** pane, which can be one of two

options. See [Migrate to Internal Percona MySQL](#) for details.

1. Select **Internal MySQL**.

Choose the location of your UAA database *

☒ Internal MySQL (preferred for complete high-availability)

☐ External (preferred if, for example, you use AWS RDS)

2. Click **Save**.
3. Ensure that you complete the [Configure Internal MySQL](#) step later in this topic to configure high availability for your internal MySQL databases.

External Database Configuration

1. From the **UAA** section in Pivotal Application Service (PAS), select **External**.

Choose the location of your UAA database *

☐ Internal MySQL (preferred for complete high-availability)

☒ External (preferred if, for example, you use AWS RDS)

Hostname *

TCP Port *

Username *

Password *

Secret

2. Enter the **Hostname** and **TCP Port** of the database from [Step 6: Create Database Instance and Databases](#) of the *Preparing to Deploy PCF on GCP* topic.
3. For **User Account and Authentication database username**, specify a unique username that can access this specific database on the database server.
4. For **User Account and Authentication database password**, specify a password for the provided username.
5. Click **Save**.

Step 11: Configure CredHub

 **Note:** Enabling CredHub is not required. However, you cannot leave the fields under **Encryption Keys** blank. If you do not intend to use CredHub, enter any text in the **Name** and **Key** fields as placeholder values.

1. Select **CredHub**.
2. Select **Internal** for your CredHub database. For GCP environments, Runtime CredHub has the following limitations:
 - If you choose **External**, Runtime CredHub does not work. See [CredHub Database Cannot be External on GCP](#).
 - Runtime CredHub only works if both the [system databases](#) and the CredHub database are set to **Internal**.

- Under **Encryption Keys**, specify one or more keys to use for encrypting and decrypting the values stored in the CredHub database.

Encryption Keys

Name *

Name of the encryption key.

Provider*

Internal

Key *

Secret

☐ Primary

- Name.** This is the name of the encryption key.
 - If you plan to use internal encryption, enter any key name.
 - If you plan to use an HSM as your encryption provider, enter a key name that already exists on your HSM or a new key name. For each new key name, CredHub generates a key in **HSM Provider Partition** that you configure below.
- Provider.** This is the provider of the encryption key. If you plan to configure an HSM provider and HSM servers below, select **HSM**. Otherwise, select **Internal**.
- Key.** If you select internal encryption, this key is used for encrypting all data. The key must be at least 20 characters long.
 - If you selected **Internal** above, enter a randomly generated value under **Key**.
 - If you selected **HSM** above, enter a placeholder value under **Key**. CredHub does not use this key for encryption. However, you cannot leave the **Key** field blank.
- Primary.** This checkbox is used for marking the key you specified above as the primary encryption key. You must mark one key as **Primary**. Do not mark more than one key as **Primary**.

 **Note:** For information about using additional keys for key rotation, see the [Rotating Runtime CredHub Encryption Keys](#) topic.

- (Optional) To configure CredHub to use an HSM, complete the following fields:

- HSM Provider Partition.** This is the name of the HSM provider partition.
- HSM Provider Partition Password.** This password is used to access the HSM provider partition.
- HSM Provider Client Certificate.** This is the client certificate for the HSM. For more information, see [Create and Register HSM Clients](#) in the

HSM Provider Partition

HSM Provider Partition Password

Secret

HSM Provider Client Certificate

Certificate PEM

Private Key PEM

[Generate RSA Certificate](#)

Preparing CredHub HSMs for Configuration topic.

- In the **HSM Provider Servers** section, click **Add** to add an HSM server. You can add multiple HSM servers. For each HSM server, complete the following fields:
 - **Host Address.** This is the host name or IP address of the HSM server.
 - **Port.** This is the port of the HSM server. If you do not know your port address, enter `1792`.
 - **Partition Serial Number.** This is the serial number of the HSM partition.
 - **HSM Certificate.** This is the certificate for the HSM server. The HSM presents this certificate to CredHub to establish a two-way TLS connection.

5. If your deployment uses any PCF services that support storing service instance credentials in CredHub and you want to enable this feature, select the **Secure Service Instance Credentials** checkbox.
6. Click **Save**.
7. Select the **Resource Config** pane.
8. Under the **Job** column of the **CredHub** row, set the number of instances to `2`. This is the minimum instance count required for high availability.
9. Click **Save**.

For more information about using CredHub for securing service instance credentials, see [Securing Service Instance Credentials with Runtime CredHub](#).

Step 12: Configure Authentication and Enterprise SSO

1. Select **Authentication and Enterprise SSO**.

Configure your user store access, which can be an internal user store (managed by Cloud Foundry's UAA) or an external user store (LDAP or SAML). You can also adjust the lifetimes of authentication tokens.

Configure your UAA user account store with either internal or external authentication mechanisms *

☒ Internal UAA (provided by Elastic Runtime; configure your password policy below)

Minimum Password Length *

Minimum Uppercase Characters Required for Password *

Minimum Lowercase Characters Required for Password *

Minimum Numerical Digits Required for Password *

Minimum Special Characters Required for Password *

Maximum Password Entry Attempts Allowed *

2. To authenticate user sign-ons, your deployment can use one of three types of user database: the UAA server's internal user store, an external SAML identity provider, or an external LDAP server.

- To use the internal UAA, select the **Internal** option and follow the instructions in the [Configuring UAA Password Policy](#) topic to configure your password policy.
- To connect to an external identity provider through SAML, scroll down to select the **SAML Identity Provider** option and follow the instructions in the [Configuring PCF for SAML](#) section of the *Configuring Authentication and Enterprise SSO for Pivotal Application Service (PAS)* topic.
- To connect to an external LDAP server, scroll down to select the **LDAP Server** option and follow the instructions in the [Configuring LDAP](#) section of the *Configuring Authentication and Enterprise SSO for PAS* topic.

3. Click **Save**.

Step 13: Configure System Databases

You can configure PAS to use Google Cloud SQL for the databases required by PAS.

 **Note:** If you are performing an upgrade, do not modify your existing internal database configuration or you may lose data. You must migrate your existing data first before changing the configuration. Contact Pivotal Support for help. See [Upgrading Pivotal Cloud Foundry](#) for additional upgrade information.

Internal Database Configuration

 **Note:** For GCP installations, Pivotal recommends selecting **External** and using Google Cloud SQL. Only use internal MySQL for non-production or test installations on GCP.

 **Note:** For Runtime CredHub to work, you must use internal MySQL. See [CredHub Database Cannot be External on GCP](#).

If you want to use internal databases for your deployment, perform the following steps:

1. Select **Databases**.
2. Select one of the **Internal Databases** options:
 - **Internal Databases - MySQL - Percona XtraDB Cluster** uses [Percona Server](#) with TLS encryption between server cluster nodes.
 - **Internal Databases - MySQL - MariaDB Galera Cluster** uses [MariaDB](#) with cluster nodes communicating over plaintext.

⚠ warning: Changing existing internal databases from **MySQL - MariaDB Galera Cluster** to **MySQL - Percona XtraDB Cluster** migrates the databases after you click **Apply Changes**, causing temporary system downtime. See [Migrate to Internal Percona MySQL](#) for details.

Choose the location of your system databases. Please consult the documentation for migrating existing installations from MariaDB to Percona. *

- ☒ Internal Databases - MySQL - Percona XtraDB Cluster
- ☐ Internal Databases - MySQL - MariaDB Galera Cluster (deprecated - planned to be removed in PAS 2.4)
- ☐ External Databases - (e.g. AWS RDS)

Save

3. Click **Save**.

Then proceed to [Step 14: \(Optional\) Configure Internal MySQL](#) to configure high availability for your internal MySQL databases.

External Database Configuration

Pivotal recommends using an external database such as Google Cloud SQL for high availability reasons.

On GCP, you can use Google Cloud SQL and use the automated backup and high availability replica features.

💡 Note: If you use external MySQL, you cannot use Runtime CredHub. See [CredHub Database Cannot be External on GCP](#).

💡 Note: To configure an external database for UAA, see the *External Database Configuration* section of [Configure UAA](#).

⚠ warning: Protect whichever database you use in your deployment with a password.

To specify your PAS databases, perform the following steps:

1. Select the **External Databases** option.
2. In the **Hostname** field, enter the IP address of the Google Cloud SQL instance that you created in [Step 6: Create Database Instance and Databases](#) of the *Preparing to Deploy Ops Manager on GCP Manually* topic. You can obtain this address from the Instances dashboard of the **SQL** configuration page in the GCP Console.
3. In the **TCP Port** field, enter `3306`.
4. Each component that requires a relational database has two corresponding fields: one for the database username and one for the database password. For each set of fields, specify the username that can access this specific database on the database server and a password for the provided username. You created these users in [Preparing to Deploy Ops Manager on GCP Manually](#).

Place the databases used by Elastic Runtime components.

Choose the location of your system databases*

☐ Internal Databases - MySQL (preferred for complete high-availability)

☒ External Databases (preferred if, for example, you use AWS RDS)

Hostname *

TCP Port *

App Usage Service Database Username *

App Usage Service Database Password *

[Change](#)

Autoscaling Service Database Username *

Autoscaling Service Database Password *

[Change](#)

Cloud Controller Database Username *

Cloud Controller Database Password *

[Change](#)

5. Click **Save**.

Step 14: (Optional) Configure Internal MySQL

 **Note:** You only need to configure this section if you have selected **Internal Databases - MySQL** in the **Databases** section.

1. Select **Internal MySQL**.
2. In the **MySQL Proxy IPs** field, enter one or more comma-delimited IP addresses that are not in the reserved CIDR range of your network. If a MySQL node fails, these proxies re-route connections to a healthy node. See the [MySQL Proxy](#) topic for more information.

Only configure this section if you selected Internal Databases - MySQL in the previous Databases section.

A proxy tier routes MySQL connections from internal components to healthy cluster nodes. Configure DNS and/or your own load balancer to point to multiple proxy instances for increased availability. TCP healthchecks can be configured against port 1936.

The automated backups functionality works with any S3-compatible file store that can receive your backup files.

MySQL Proxy IPs

MySQL Service Hostname

- For **MySQL Service Hostname**, enter an IP address or hostname for your load balancer. If a MySQL proxy fails, the load balancer re-routes connections to a healthy proxy. If you leave this field blank, components are configured with the IP address of the first proxy instance entered above.

 **warning:** You must configure a load balancer to achieve complete high availability.

- In the **Replication canary time period** field, leave the default of 30 seconds or modify the value based on the needs of your deployment. Lower numbers cause the canary to run more frequently, which means that the canary reacts more quickly to replication failure but adds load to the database.
- In the **Replication canary read delay** field, leave the default of 20 seconds or modify the value based on the needs of your deployment. This field configures how long the canary waits, in seconds, before verifying that data is replicating across each MySQL node. Clusters under heavy load can experience a small replication lag as write-sets are committed across the nodes.
- (**Required**): In the **E-mail address** field, enter the email address where the MySQL service sends alerts when the cluster experiences a replication issue or when a node is not allowed to auto-rejoin the cluster.
- To prohibit the creation of command line history files on the MySQL nodes, deselect the **Allow Command History** checkbox.
- To allow the admin and roadmin to connect from any remote host, enable the **Allow Remote Admin Access** checkbox. When the checkbox is disabled, admins must `bosh ssh` into each MySQL VM to connect as the MySQL super user.

 **Note:** Network configuration and Application Security Groups restrictions may still limit a client's ability to establish a connection with the databases.

- For **Cluster Probe Timeout**, enter the maximum amount of time, in seconds, that a new node will search for existing cluster nodes. If left blank, the

Replication canary time period *

Replication canary read delay *

E-mail address (required) *

☒ Allow Command History

Cluster Probe Timeout

default value is 10 seconds.

10. For **Max Connections**, enter the maximum number of connections allowed to the database. If left blank, the default value is 1500.

11. If you want to log audit events for internal MySQL, select **Enable server activity logging** under **Server Activity Logging**.

- a. For the **Event types** field, you can enter the events you want the MySQL service to log. By default, this field includes `connect` and `query`, which tracks who connects to the system and what queries are processed.

Server Activity Logging*

☐ Disable server activity logging

☒ Enable server activity logging

Event types *

Load Balancer Healthy Threshold *

Load Balancer Unhealthy Threshold *

Save

12. Enter values for the following fields:

- o **Load Balancer Healthy Threshold:** Specifies the amount of time, in seconds, to wait until declaring the MySQL proxy instance started. This allows an external load balancer time to register the instance as healthy.
- o **Load Balancer Unhealthy Threshold:** Specifies the amount of time, in seconds, that the MySQL proxy continues to accept connections before shutting down. During this period, the healthcheck reports as unhealthy to cause load balancers to fail over to other proxies. You must enter a value greater than or equal to the maximum time it takes your load balancer to consider a proxy instance unhealthy, given repeated failed healthchecks.

13. If you want to enable the MySQL interruptor feature, select the checkbox to **Prevent node auto re-join**. This feature stops all writes to the MySQL database if it notices an inconsistency in the dataset between the nodes. For more information, see the [Interruptor](#) section in the MySQL for PCF documentation.

14. Click **Save**.

Step 15: Configure File Storage

To minimize system downtime, Pivotal recommends using highly resilient and redundant *external* filestores for your Pivotal Application Service (PAS) file storage.

When configuring file storage for the Cloud Controller in PAS, you can select one of the following:

- Internal WebDAV filestore
- External S3-compatible or Ceph-compatible filestore
- External Google Cloud Storage with Access Key and Secret Key
- External Google Cloud Storage with Service Account
- External Azure Cloud Storage

For production-level PCF deployments on GCP, Pivotal recommends selecting **External Google Cloud Storage**. For more information about production-level PCF deployments on GCP, see the [Reference Architecture for Pivotal Cloud Foundry on GCP](#).

For additional factors to consider when selecting file storage, see the [Considerations for Selecting File Storage in Pivotal Cloud Foundry](#) topic.

Internal Filestore

Internal file storage is only appropriate for small, non-production deployments.

To use the PCF internal filestore, perform the following steps:

1. In the Pivotal Application Service (PAS) tile, select **File Storage**.
2. Select **Internal WebDAV**, and click **Save**.

External Google Cloud Storage

PAS can use Google Cloud Storage (GCS) as its external filestore by using either a GCP interoperable storage access key or your GCS Service Account. See below for how to configure each option.

External Google Cloud Storage with Access Key and Secret Key

1. Select the **External Google Cloud Storage with Access Key and Secret Key** option

This section determines where you would like to place your Application Service Cloud Controller's file storage.

Configure your Cloud Controller's filesystem*

- ☐ Internal WebDAV (provided by Application Service)
- ☐ External S3-Compatible File Store (if you want to use a service like S3 or Ceph)
- ☒ External Google Cloud Storage with Access Key and Secret Key

Access Key *

Secret Key *

Buildpacks Bucket Name *

Bucket for storing app buildpacks.

Droplets Bucket Name *

Packages Bucket Name *

Resources Bucket Name *

- ☐ External Google Cloud Storage with Service Account
- ☐ External Azure Storage

2. Enter values for **Access Key** and **Secret Key**. To obtain the values for these fields:

- a. In the GCP Console, navigate to the **Storage** tab, then click **Settings**.
- b. Click **Interoperability**.
- c. If necessary, click **Enable interoperability access**. If interoperability access is already enabled, confirm that the default project matches the project where you are installing PCF.

- d. Click **Create a new key**.
- e. Copy and paste the generated values into the corresponding PAS fields. PCF uses these values for authentication when connecting to Google Cloud Storage.
- f. Enter the names of the storage buckets you created in [Preparing to Deploy Ops Manager on GCP Manually](#):
 - **Buildpacks Bucket Name:** MY-PCF-buildpacks
 - **Droplets Bucket Name:** MY-PCF-droplets
 - **Resources Bucket Name:** MY-PCF-resources
 - **Packages Bucket Name:** MY-PCF-packages
- g. Click **Save**.

External Google Cloud Storage with Service Account

1. Select the **External Google Cloud Storage with Service Account** option

Configure your Cloud Controller's filesystem*

☐ Internal WebDAV (provided by Application Service)
☐ External S3-Compatible File Store (if you want to use a service like S3 or Ceph)
☐ External Google Cloud Storage with Access Key and Secret Key
☒ External Google Cloud Storage with Service Account

GCP Project ID *

GCP Service Account Email *

 Your Google Cloud Platform Service Account Email.

GCP Service Account Key JSON *

Buildpacks Bucket Name *

- a. For **GCP Project ID** enter the Project ID on your GCP Console that you want to use for your PAS file storage.
- b. For **GCP Service Account Email** enter the email address associated with your GCP account.
- c. For **GCP Service Account JSON** enter the account key that you use to access the specified GCP project, in JSON format.
- d. Enter the names of the storage buckets you created in [Preparing to Deploy Ops Manager on GCP Manually](#):
 - **Buildpacks Bucket Name:** MY-PCF-buildpacks
 - **Droplets Bucket Name:** MY-PCF-droplets
 - **Resources Bucket Name:** MY-PCF-resources
 - **Packages Bucket Name:** MY-PCF-packages
- e. Click **Save**.

Other IaaS Storage Options

[Azure Storage](#) and [External S3-Compatible File Storage](#) are also available as file storage options, but Pivotal does not recommend these for a typical PCF on GCP installation.

Step 16: (Optional) Configure System Logging

You can configure system logging in PAS to forward log messages from PAS component VMs to an external service. Pivotal recommends forwarding logs to an external service for use in troubleshooting.

Note: The following instructions explain how to configure system logging for PAS component VMs. To forward logs from PCF tiles to an external service, you must also configure system logging in each tile. See the documentation for the given tiles for information about configuring system logging.

To configure system logging in PAS, do the following:

1. In the PAS **Settings** tab, select the **System Logging** pane. The following image shows the **System Logging** pane.

Optionally configure rsyslog to forward platform component logs to an external service. If you do not fill these fields, platform logs will not be forwarded but will remain available on the component VMs and for download via Ops Manager.

Address

Port

Transport Protocol

Encrypt syslog using TLS?*

- ☒ No
☐ Yes

Syslog Drain Buffer Size (# of messages) *

☒ Include container metrics in SysLog Drains

☒ Enable Cloud Controller security event logging

☐ Use TCP for file forwarding local transport

☒ Don't Forward Debug Logs

Custom rsyslog Configuration

Save

2. For **Address**, enter the IP address of the syslog server.
3. For **Port**, enter the port of the syslog server. The default port for a syslog server is `514`.

Note: The host must be reachable from the PAS network and accept UDP or TCP connections. Ensure the syslog server listens on external interfaces.

4. For **Transport Protocol**, select a transport protocol for log forwarding.
5. For **Encrypt syslog using TLS?**, select **Yes** to use TLS encryption when forwarding logs to a remote server.
 - a. For **Permitted Peer**, enter either the name or SHA1 fingerprint of the remote peer.
 - b. For **TLS CA Certificate**, enter the TLS CA certificate for the remote server.
6. For **Syslog Drain Buffer Size**, enter the number of messages from the Loggregator Agent that the Doppler server can store before it begins to drop messages. See the [Loggregator Guide for Cloud Foundry Operators](#) topic for more details.
7. Disable the **Include container metrics in Syslog Drains** checkbox to prevent the [CF Drain CLI plugin](#) from including app container metrics in syslog drains. This feature is enabled by default.

8. Enable the **Enable Cloud Controller security event logging** checkbox to include security events in the log stream. This feature logs all API requests, including the endpoint, user, source IP address, and request result, in the Common Event Format (CEF).
9. Enable the **Use TCP for file forwarding local transport** checkbox to transmit logs over TCP. This prevents log truncation, but may cause performance issues.
10. Disable the **Don't Forward Debug Logs** checkbox to forward DEBUG syslog messages to an external service. This checkbox is enabled by default.

 **Note:** Some PAS components generate a high volume of DEBUG syslog messages. Enabling the **Don't Forward Debug Logs** checkbox prevents PAS components from forwarding the DEBUG syslog messages to external services. However, PAS still writes the messages to the local disk.

11. For **Custom rsyslog Configuration**, enter a custom syslog rule. For more information about adding custom syslog rules, see [Customizing Syslog Rules](#).
12. Click **Save**.

To configure Ops Manager for system logging, see the [Settings](#) section in the *Using the Ops Manager Interface* topic.

Step 17: (Optional) Customize Apps Manager

This section describes how to configure **Custom Branding** and **Apps Manager** to customize the appearance and functionality of Apps Manager. For more information about the **Custom Branding** configuration settings, see [Custom Branding Apps Manager](#).

1. Select **Custom Branding**. Use this section to configure the text, colors, and images of the interface that developers see when they log in, create an account, reset their password, or use Apps Manager.

Customize colors, images, and text for Apps Manager and the Cloud Foundry login portal.

Company Name

Accent Color

2. Click **Save** to save your settings in this section.
3. Select **Apps Manager**.

Configure Apps Manager

☒ Enable Invitations

☐ Display Marketplace Service Plan Prices

Supported currencies as JSON *

```
{ "usd": "$", "eur": "€" }
```

Product Name

Marketplace Name

Customize Sidebar Links Add

You may configure up to 10 links in the Apps Manager sidebar.

- ▶ Marketplace 🗑
- ▶ Docs 🗑
- ▶ Tools 🗑

Apps Manager Memory Usage (MB) (min: 128)

Invitations Memory Usage (MB) (min: 256)

Apps Manager Polling Interval *

30

Apps manager polling interval in seconds. As a workaround to reduce load on the Cloud Controller API, increase the polling interval or set to 0 to stop polling. Values between 0 and 30 will default to 30 seconds.

Save

4. Select **Enable Invitations** to enable invitations in Apps Manager. Space Managers can invite new users for a given space, Org Managers can invite new users for a given org, and Admins can invite new users across all orgs and spaces. See the [Inviting New Users](#) section of the *Managing User Roles with Apps Manager* topic for more information.
5. Select **Display Marketplace Service Plan Prices** to display the prices for your services plans in the Marketplace.
6. Enter the **Supported currencies as JSON** to appear in the Marketplace. Use the format `{ "CURRENCY-CODE": "SYMBOL" }`. This defaults to `{ "usd": "$", "eur": "€" }`.
7. Use **Product Name**, **Marketplace Name**, and **Customize Sidebar Links** to configure page names and sidebar links in the **Apps Manager** and **Marketplace** pages.
8. The **Apps Manager Memory Usage (MB)** field sets the memory limit with which to deploy the Apps Manager app. Use this field to increase the memory limit if the app fails to start with an `out of memory` error.
9. The **Invitations Memory Usage (MB)** field sets the memory limit with which to deploy the Invitations app. Use this field to increase the memory limit if the app fails to start with an `out of memory` error.

10. The **Apps Manager Polling Interval** field provides a temporary fix if Apps Manager usage degrades Cloud Controller response times. In this case, you can use this field to reduce the load on the Cloud Controller and ensure Apps Manager remains available while you troubleshoot the Cloud Controller. Pivotal recommends that you do not keep this field modified as a long term fix because it can degrade Apps Manager performance. You can optionally do the following:

- Increase the polling interval above the default of `30` seconds.

 **Note:** If you enter a value between `0` and `30`, the field is automatically set to `30`.

- Disable polling by entering `0`. This stops Apps Manager from refreshing data automatically, but users can update displayed data by reloading Apps Manager manually.

11. Click **Save** to save your settings in this section.

Step 18: (Optional) Configure Email Notifications

PAS uses SMTP to send invitations and confirmations to Apps Manager users. You must complete the **Email Notifications** page if you want to enable end-user self-registration.

1. Select **Email Notifications**.

Configure Simple Mail Transfer Protocol for the Notifications application to send email notifications about your deployment. This application is deployed as an errand in Elastic Runtime. If you do not need this service, leave this section blank and disable the Notifications and Notifications UI errands.

From Email

Address of SMTP Server

Port of SMTP Server

SMTP Server Credentials

[Change](#)

☒ SMTP Enable Automatic STARTTLS

SMTP Authentication Mechanism*

SMTP CRAMMD5 secret

2. Enter your reply-to and SMTP email information.

 **Note:** For GCP, you must use port `2525`. Ports `25` and `587` are not allowed on GCP Compute Engine.

3. Verify your authentication requirements with your email administrator and use the **SMTP Authentication Mechanism** dropdown to select `None`, `Plain`, or `CRAMMD5`. If you have no SMTP authentication requirements, select `None`.

- If you selected `CRAMMD5` as your authentication mechanism, enter a secret in the **SMTP CRAMMD5 secret** field.
- Click **Save**.

Note: If you do not configure the SMTP settings using this form, the administrator must create orgs and users using the cf CLI. See [Creating and Managing Users with the cf CLI](#) for more information.

Step 19: (Optional) Configure App Autoscaler

To use App Autoscaler, you must create an instance of the service and bind it to an app. To create an instance of App Autoscaler and bind it to an app, see [Set Up App Autoscaler](#) in the *Scaling an Application Using App Autoscaler* topic.

- Click **App Autoscaler**.

Configure the App Autoscaler

Autoscaler Instance Count (min: 1) *

Autoscaler API Instance Count (min: 1) *

Metric Collection Interval (min: 60, max: 3600) (min: 60, max: 3600) *

Scaling Interval (min: 15, max: 120) (min: 15, max: 120) *

☐ Verbose Logging

☐ Disable API Connection Pooling

☒ Enable Notifications

- Review the following settings:

- Autoscaler Instance Count:** How many instances of the App Autoscaler service you want to deploy. The default value is `3`. For high availability, set this number to `3` or higher. You should set the instance count to an odd number to avoid split-brain scenarios during leadership elections. Larger environments may require more instances than the default number.
- Autoscaler API Instance Count:** How many instances of the App Autoscaler API you want to deploy. The default value is `1`. Larger environments may require more instances than the default number.
- Metric Collection Interval:** How many seconds of data collection you want App Autoscaler to evaluate when making scaling decisions. The minimum interval is 60 seconds, and the maximum interval is 3600 seconds. The default value is `120`. Increase this number if the metrics you use in your scaling rules are emitted less frequently than the existing Metric Collection Interval.
- Scaling Interval:** How frequently App Autoscaler evaluates an app for scaling. The minimum interval is 15 seconds, and the maximum interval is 120 seconds. The default value is `35`.
- Verbose Logging** (checkbox): Enables verbose logging for App Autoscaler. Verbose logging is disabled by default. Select this checkbox to see more detailed logs. Verbose logs show specific reasons why App Autoscaler scaled the app, including information about minimum and maximum instance limits, App Autoscaler's status. For more information about App Autoscaler logs, see [App Autoscaler Events and Notifications](#).
- Disable API Connection Pooling:** API connection pooling increases performance by reducing the cost associated with establishing new connections. If you do not want to keep connections open for reuse, select this option.

3. Click **Save**.

Step 20: Configure Cloud Controller

1. Click **Cloud Controller**.

Configure the Cloud Controller

Cloud Controller DB Encryption Key

Secret

Enabling CF API Rate Limiting will prevent API consumers from overwhelming the platform API servers. Limits are imposed on a per-user or per-client basis and reset on an hourly interval. *

☐ Enable
 ☒ Disable

Save

2. Enter your **Cloud Controller DB Encryption Key** if all of the following are true:

- You deployed Pivotal Application Service (PAS) previously.
- You then stopped PAS or it crashed.
- You are re-deploying PAS with a backup of your Cloud Controller database.

See [Backing Up Pivotal Cloud Foundry](#) for more information.

3. CF API Rate Limiting prevents API consumers from overwhelming the platform API servers. Limits are imposed on a per-user or per-client basis and reset on an hourly interval.

To disable CF API Rate Limiting, select **Disable** under **Enable CF API Rate Limiting**. To enable CF API Rate Limiting, perform the following steps:

- Under **Enable CF API Rate Limiting**, select **Enable**.
- For **General Limit**, enter the number of requests a user or client is allowed to make over an hour interval for all endpoints that do not have a custom limit. The default value is `2000`.
- For **Unauthenticated Limit**, enter the number of requests an unauthenticated client is allowed to make over an hour interval. The default value is `100`.

4. Click **Save**.

Step 21: Configure Smoke Tests

The Smoke Tests errand runs basic functionality tests against your Pivotal Application Service (PAS) deployment after an installation or update. In this section, choose where to run smoke tests. In the **Errands** section, you can choose whether or not to run the Smoke Tests errand.

1. Select **Smoke Tests**.
2. If you have a shared apps domain, select **Temporary space within the system organization**, which creates a temporary space within the `system` organization for running smoke tests and deletes the space afterwards. Otherwise, select **Specified org and space** and complete the fields to specify where you want to run smoke tests.

Specify a Cloud Foundry organization and space where smoke tests can run if in the future you delete your Elastic Runtime deployment domains.

Choose where to deploy applications when running the smoke tests *

- ☐ Temporary space within the system organization (This is deleted after smoke tests finish.)
- ☒ Specified org and space (The org and space must have a domain available for routing.)

Organization *

Space *

Domain *

Save

3. Click **Save**.

Step 22: (Optional) Enable Advanced Features

The **Advanced Features** section of Pivotal Application Service (PAS) includes new functionality that may have certain constraints. Although these features are fully supported, Pivotal recommends caution when using them in production environments.

Diego Cell Memory and Disk Overcommit

If your apps do not use the full allocation of disk space and memory set in the **Resource Config** tab, you might want use this feature. These fields control the amount to overcommit disk and memory resources to each Diego Cell VM.

For example, you might want to use the overcommit if your apps use a small amount of disk and memory capacity compared to the amounts set in the **Resource Config** settings for **Diego Cell**.

Note: Due to the risk of app failure and the deployment-specific nature of disk and memory use, Pivotal has no recommendation about how much, if any, memory or disk space to overcommit.

To enable overcommit, do the following:

1. Select **Advanced Features**.

Cell Memory Capacity (MB) (min: 1)

Cell Disk Capacity (MB) (min: 1)

2. Enter the total desired amount of Diego cell memory value in the **Cell Memory Capacity (MB)** field. Refer to the **Diego Cell** row in the **Resource Config** tab for the current Cell memory capacity settings that this field overrides.
3. Enter the total desired amount of Diego cell disk capacity value in the **Cell Disk Capacity (MB)** field. Refer to the **Diego Cell** row in the **Resource Config** tab for the current Cell disk capacity settings that this field overrides.
4. Click **Save**.

 **Note:** Entries made to each of these two fields set the total amount of resources allocated, not the overage.

Whitelist for Non-RFC-1918 Private Networks

Some private networks require extra configuration so that internal file storage (WebDAV) can communicate with other PCF processes.

The **Whitelist for non-RFC-1918 Private Networks** field is provided for deployments that use a non-RFC 1918 private network. This is typically a private network other than `10.0.0.0/8`, `172.16.0.0/12`, or `192.168.0.0/16`.

Most PCF deployments do not require any modifications to this field.

To add your private network to the whitelist, do the following:

1. Select **Advanced Features**.
2. Append a new `allow` rule to the existing contents of the **Whitelist for non-RFC-1918 Private Networks** field.

Whitelist for non-RFC-1918 Private Networks *

allow 10.0.0.0/8;;allow 172.16.0.0/12;;allow .

If your Elastic Runtime deployment is using a private network that is not RFC 1918 (10.0.0.0/8, 172.16.0.0/12, 192.168.0.0/16), then you must type in "allow <your-network>;" here. It is important to include the word "allow" and the semi-colon at the end. For example, "allow 172.99.0.0/24;"

Include the word `allow`, the network CIDR range to allow, and a semi-colon (`;`) at the end. For example: `allow 172.99.0.0/24;`

3. Click **Save**.

CF CLI Connection Timeout

The **CF CLI Connection Timeout** field allows you to override the default five second timeout of the Cloud Foundry Command Line Interface (cf CLI) used within your PCF deployment. This timeout affects the cf CLI command used to push PAS errand apps such as Notifications, Autoscaler, and Apps Manager.

Set the value of this field to a higher value, in seconds, if you are experiencing domain name resolution timeouts when pushing errands in PAS.

To modify the value of the **CF CLI Connection Timeout**, perform the following steps:

1. Select **Advanced Features**.

CF CLI Connection Timeout

15

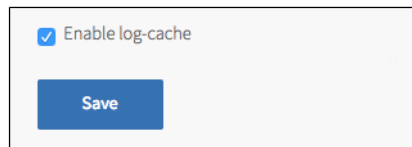

2. Add a value, in seconds, to the **CF CLI Connection Timeout** field.
3. Click **Save**.

Log Cache

Log Cache is an in-memory caching layer for logs and metrics. This Loggregator feature lets users filter and query logs through a CLI or API endpoints. Cached logs are available on demand. For more information about Log Cache, see [Enable Log Cache](#) in the *Configuring Logging in PASTopic*.

To configure the **Enable log-cache** checkbox, do the following:

1. Select **Advanced Features**.

A screenshot of a configuration panel. It contains a checkbox labeled 'Enable log-cache' which is checked. Below the checkbox is a blue button labeled 'Save'.

2. Select or deselect the **Enable log-cache** checkbox.
3. Click **Save**.

Database Connection Limits

You can configure the maximum number of concurrent database connections that diego and container networking components can have. Use the field beginning with **Maximum number of open connections...** for a given component. The placeholder values for each field are the default values.

When there are not enough connections available, such as during a time of heavy load, components may experience degraded performance and sometimes failure. To resolve or prevent this, you can increase and fine-tune database connection limits for the component.

⚠ warning: Decreasing the value of this field for a component may affect the amount of time it takes for it to respond to requests.

Step 23: Configure Errands

Errands are scripts that Ops Manager runs automatically when it installs or uninstalls a product, such as a new version of Pivotal Application Service (PAS). There are two types of errands: *post-deploy errands* run after the product is installed, and *pre-delete errands* run before the product is uninstalled.

By default, Ops Manager always runs all errands.

The PAS tile **Errands** pane lets you change these run rules. For each errand, you can select **On** to run it always or **Off** to never run it.

For more information about how Ops Manager manages errands, see the [Managing Errands in Ops Manager](#) topic.

💡 Note: Several errands, such as App Autoscaler and Notifications, deploy apps that provide services for your deployment. When one of these apps is running, selecting **Off** for the corresponding errand on a subsequent installation does not stop the app.

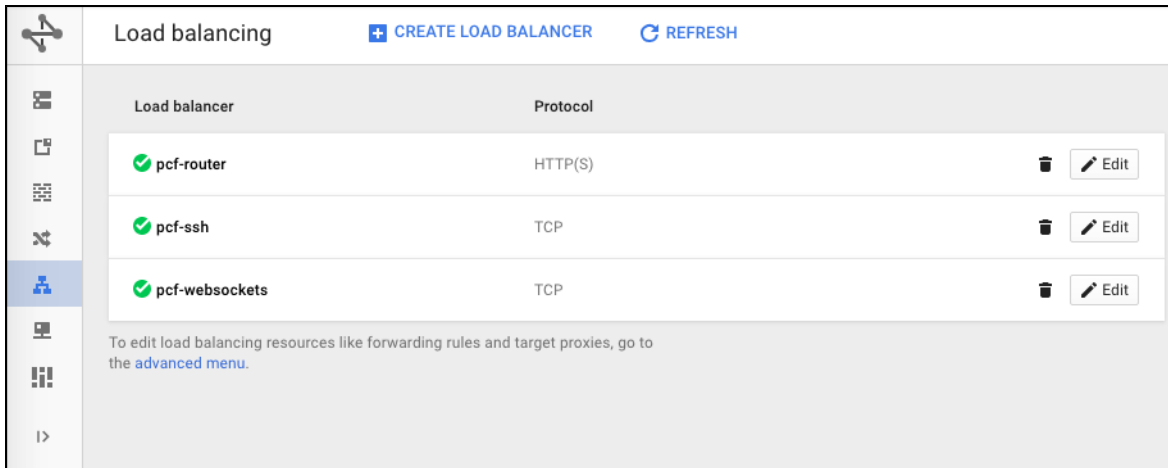

- **Smoke Test Errand** verifies that your deployment can do the following:
 - Push, scale, and delete apps
 - Create and delete orgs and spaces
- **Usage Service Errand** deploys the Pivotal Usage Service application, which Apps Manager depends on.
- **Apps Manager Errand** deploys Apps Manager, a dashboard for managing apps, services, orgs, users, and spaces. Until you deploy Apps Manager, you must perform these functions through the cf CLI. After Apps Manager has been deployed, Pivotal recommends setting this errand to **Off** for subsequent PAS deployments. For more information about Apps Manager, see the [Getting Started with the Apps Manager](#) topic.
- **Notifications Errand** deploys an API for sending email notifications to your PCF platform users.

💡 Note: The Notifications app requires that you [configure SMTP](#) with a username and password, even if you set the value of **SMTP Authentication Mechanism** to `none`.

- **Notifications UI Errand** deploys a dashboard for users to manage notification subscriptions.
- **App Autoscaler Errand** enables you to configure your apps to automatically scale in response to changes in their usage load. See the [Scaling an Application Using Autoscaler](#) topic for more information.
- **NFS Broker Errand** enables you to use NFS Volume Services by installing the NFS Broker app in PAS. See the [Enabling NFS Volume Services](#) topic for more information.

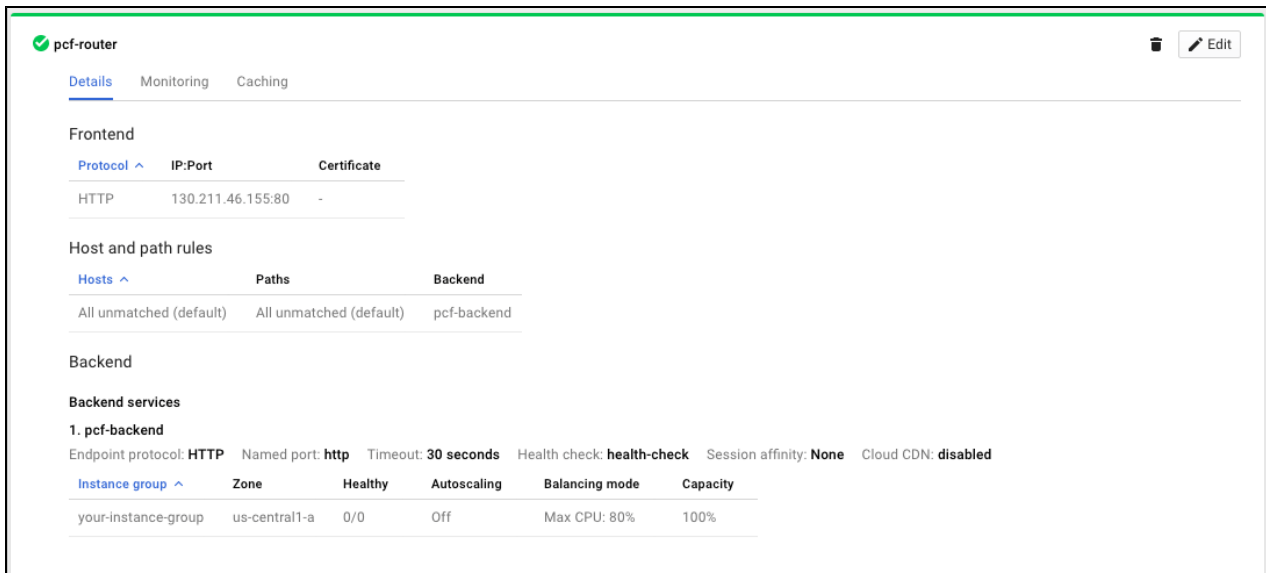

Step 24: Configure Load Balancers

1. Navigate to the GCP Console and click **Load balancing**.

You should see the SSH load balancer, the HTTP(S) load balancer, the TCP WebSockets load balancer, and the TCP router that you created in the *Preparing to Deploy Ops Manager on GCP* topic.

- Record the name of your SSH load balancer and your TCP WebSockets load balancer, `MY-PCF-wss-logs` and `MY-PCF-ssh-proxy`.
- Click your HTTP(S) load balancer, `MY-PCF-global-pcf`.

- Under **Backend services**, record the name of the backend service of the HTTP(S) load balancer, `MY-PCF-http-lb-backend`.
- In the PAS tile, click **Resource Config**.

Resource Config

| JOB | INSTANCES | PERSISTENT DISK TYPE | VM TYPE | LOAD BALANCERS | INTERNET CONNECTED |
|-------------------------------|--------------|----------------------|---|----------------|-------------------------------------|
| Consul | 1 | Automatic: 1 GB | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| NATS | 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| File Storage | Automatic: 1 | Automatic: 100 GB | Automatic: medium.mem (cpu: 1, ram: 6 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| MySQL Proxy | 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| MySQL Server | 1 | Automatic: 100 GB | Automatic: large.disk (cpu: 2, ram: 8 GB, disk: 64 GB) | | <input checked="" type="checkbox"/> |
| Backup Prepare Node | Automatic: 1 | Automatic: 200 GB | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| Diego BBS | 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| UAA | 1 | None | Automatic: medium.disk (cpu: 2, ram: 4 GB, disk: 32 GB) | | <input checked="" type="checkbox"/> |
| Cloud Controller | 1 | None | Automatic: medium.disk (cpu: 2, ram: 4 GB, disk: 32 GB) | | <input checked="" type="checkbox"/> |
| HAProxy | Automatic: 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| Router | 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | pcf-web-elb | <input checked="" type="checkbox"/> |
| MySQL Monitor | Automatic: 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| Clock Global | Automatic: 1 | None | Automatic: medium.disk (cpu: 2, ram: 4 GB, disk: 32 GB) | | <input checked="" type="checkbox"/> |
| Cloud Controller Worker | 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| Diego Brain | 1 | Automatic: 1 GB | Automatic: small (cpu: 1, ram: 2 GB, disk: 8 GB) | pcf-ssh-elb | <input checked="" type="checkbox"/> |
| Diego Cell | 1 | None | Automatic: xlarge.disk (cpu: 4, ram: 16 GB, disk: 128 GB) | | <input checked="" type="checkbox"/> |
| Loggregator Trafficcontroller | 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| Syslog Adapter | 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| Syslog Scheduler | 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| Doppler Server | 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| TCP Router | 0 | Automatic: 1 GB | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | pcf-tcp-elb | <input checked="" type="checkbox"/> |
| CredHub | Automatic: 0 | None | Automatic: large (cpu: 2, ram: 8 GB, disk: 16 GB) | | <input checked="" type="checkbox"/> |

Save

6. Under the **LOAD BALANCERS** column of the **Router** row, enter a comma-delimited list consisting of the name of your TCP WebSockets load balancer and the name of your HTTP(S) load balancer backend with the protocol prepended. For example, `tcp:MY-PCF-wss-logs,http:MY-PCF-http-lb-backend`.

 **Note:** Do not add a space between key/value pairs in the **LOAD BALANCER** field or it will fail.

 **Note:** If you are using HAProxy in your deployment, then enter the above load balancer values in the **LOAD BALANCERS** field of the **HAProxy** row instead of the **Router** row. For a high availability configuration, scale up the HAProxy job to more than one instance.

7. If you have enabled TCP routing in the [Networking](#) pane and set up the [TCP Load Balancer in GCP](#), add the name of your TCP load balancer, prepended with `tcp:`, to the **LOAD BALANCERS** column of the TCP Router row. For example, `tcp:pcf-tcp-router`.
8. Enter the name of you SSH load balancer depending on which release you are using.
- PAS:** Under the **LOAD BALANCERS** column of the **Diego Brain** row, enter the name of your SSH load balancer prepended with `tcp:`. For example, `tcp:MY-PCF-ssh-proxy`.
 - Small Footprint Runtime:** Under the **LOAD BALANCERS** column of the **Control** row, enter the name of your SSH load balancer prepended with `tcp:`.
9. Verify that the **Internet Connected** checkbox for every job is unchecked. When preparing your GCP environment, you provisioned a Network Address Translation (NAT) box to provide Internet connectivity to your VMs instead of providing them with public IP addresses to allow the jobs to reach the Internet.

 **Note:** If you want to provision a Network Address Translation (NAT) box to provide Internet connectivity to your VMs instead of providing them with public IP addresses, deselect the **Internet Connected** checkboxes. For more information about using NAT in GCP, see the [GCP documentation](#).

10. Click **Save**.

Step 25: (Optional) Scale Down and Disable Resources

 **Note:** The **Resource Config** pane has fewer VMs if you are installing the [Small Footprint Runtime](#).

 **Note:** The Small Footprint Runtime does not default to a highly available configuration. It defaults to the minimum configuration. If you want to make the Small Footprint Runtime highly available, scale the **Compute**, **Router**, and **Database** VMs to instances and scale the **Control** VM to instances.

Pivotal Application Service (PAS) defaults to a highly available resource configuration. However, you may need to perform additional procedures to make your deployment highly available. See the [Zero Downtime Deployment and Scaling in CF](#) and the [Scaling Instances in PAS](#) topics for more information.

If you do not want a highly available resource configuration, you must scale down your instances manually by navigating to the **Resource Config** section and using the dropdowns under **Instances** for each job.

By default, PAS also uses an internal filestore and internal databases. If you configure PAS to use external resources, you can disable the corresponding system-provided resources in Ops Manager to reduce costs and administrative overhead.

To disable specific VMs in Ops Manager, do the following:

1. Click **Resource Config**.
2. If you configured PAS to use an external S3-compatible filestore, enter in **Instances** in the **File Storage** field.
3. If you selected **External** when configuring the UAA, System, and CredHub databases, edit the following fields:
 - **MySQL Proxy:** Enter in **Instances**.
 - **MySQL Server:** Enter in **Instances**.
 - **MySQL Monitor:** Enter in **Instances**.
4. If you disabled TCP routing, enter **Instances** in the **TCP Router** field.
5. If you are not using HAProxy, enter **Instances** in the **HAProxy** field.
6. Click **Save**.

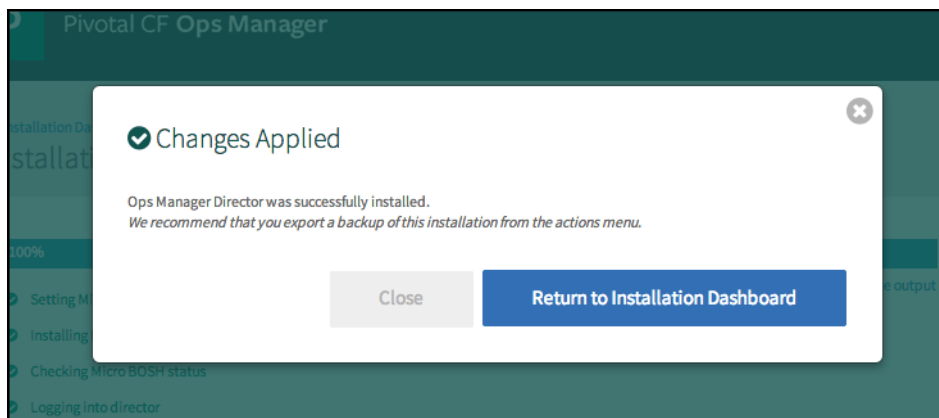

Step 26: Download Stemcell

This step is only required if your Ops Manager does not already have the stemcell version required by PAS. For more information about importing stemcells, see [Importing and Managing Stemcells](#).

1. Open the [Stemcell product page](#)  in the Pivotal Network. *Note, you may have to log in.*
2. Download the appropriate stemcell version targeted for your IaaS.
3. Navigate to **Stemcell Library** in the **Installation Dashboard**.
4. Click **Import Stemcell** to import the downloaded stemcell file.
5. When prompted, enable the Ops Manager product checkbox to stage your stemcell.
6. Click **Apply Stemcell to Products**.

Step 27: Complete the PAS Installation

1. Click the **Installation Dashboard** link to return to the Installation Dashboard.
2. Click **Apply Changes**.
The install process generally requires a minimum of 90 minutes to complete. The image shows the Changes Applied window that displays when the installation process successfully completes.

Installing PCF on GCP Using Terraform

This topic explains how to install PCF on GCP using Terraform.

Overview

You can install PCF on GCP with either the Pivotal Application Service (PAS) or Pivotal Container Service (PKS) runtime.

To install PCF on GCP using Terraform, do one of the following:

- Install with PAS. See [Install on PAS Using Terraform](#).
- Install with PKS. See [Install on PKS Using Terraform](#).

Install with PAS Using Terraform

To install with PAS using Terraform, do the following:

1. Deploy Ops Manager. See [Deploying Ops Manager on GCP Using Terraform](#).
2. Configure BOSH Director. See [Configuring BOSH Director on GCP Using Terraform](#).
3. (Optional) Configure a shared VPC. See [\(Optional\) Configuring a Shared VPC on GCP](#).
4. Configure PAS. See [Deploying PAS on GCP Using Terraform](#).

Install with PKS Using Terraform

To install with PKS using Terraform, do the following:

1. Deploy Ops Manager. See [Deploying Ops Manager on GCP Using Terraform](#).
2. Configure BOSH Director. See [Configuring BOSH Director on GCP Using Terraform](#).
3. (Optional). Configure a shared VPC. See [\(Optional\) Configuring a Shared VPC on GCP](#).
4. Configure PKS. See [Installing PKS on GCP](#) [↗](#).

Deploying Ops Manager on GCP Using Terraform

Page last updated:

This guide describes the preparation steps required to install Pivotal Cloud Foundry (PCF) on Google Cloud Platform (GCP) using Terraform templates.

The Terraform template for PCF on GCP describes a set of GCP resources and properties. For more information about how Terraform creates resources in GCP, see the [Google Cloud Provider](#) topic on the Terraform site.

You may also find it helpful to review different deployment options in the [Reference Architecture for Pivotal Cloud Foundry on GCP](#).

Prerequisites

In addition to fulfilling the prerequisites listed in the [Installing Pivotal Cloud Foundry on GCP](#) topic, ensure you have the following:

- The [Terraform CLI](#)
- The [Google Cloud SDK](#)
- In your GCP project, enable the following APIs:
 - [Identity and Access Management](#)
 - [Cloud Resource Manager](#)
 - [Cloud DNS](#)
 - [Cloud SQL API](#)
 - [Compute Engine API](#)

Step 1: Obtain a GCP Service Account Key File

To use the Terraform templates to create the necessary infrastructure resources for PCF, you need a service account key file.

To create an account key file, follow the procedure below corresponding to your own use case.

- **I already have a service account I want to use:**

1. Navigate to the GCP console.
2. Select **IAM** and locate your service account.
3. From the **Options** column, open the dropdown and click **Create Key**.

- **I want to create a new service account:**

1. Open a terminal window.
2. To create a service account using the gcloud CLI, run the following command:

```
gcloud iam service-accounts create ACCOUNT-NAME
```

3. To create a key file for your service account, run the following command:

```
gcloud iam service-accounts keys create "terraform.key.json" --iam-account "ACCOUNT-NAME@PROJECT-ID.iam.gserviceaccount.com"
```

4. To bind the service account to your project and give it the owner role, run the following command:

```
gcloud projects add-iam-policy-binding PROJECT-ID --member 'serviceAccount:ACCOUNT-NAME@PROJECT-ID.iam.gserviceaccount.com' --role 'roles
```

Where:

- `ACCOUNT-NAME` is the name you want to apply to the new account.
- `PROJECT-ID` is your Google Cloud Platform Project ID.

Step 2: Download Templates and Edit Variables File

Before you can run Terraform commands to provision infrastructure resources, you must download the GCP Terraform Templates and create a Terraform template variables file as described below:

1. On [Pivotal Network](#), navigate to the Pivotal Application Service (PAS) release.
2. Download the GCP Terraform ZIP file.
3. Extract the contents of the ZIP file.
4. Move the extracted folder to the `workspace` directory on your local machine.
5. On the command line, navigate to the directory. For example:

```
$ cd ~/workspace/pivotal-cf-terraforming-gcp
```

6. Navigate to the `terraforming-pas` or `terraforming-pks` directory that contains the Terraform files for your runtime.
7. In the runtime directory, create a text file named `terraform.tfvars`.
8. Open the `terraform.tfvars` file and add the following:

```
env_name      = "YOUR-ENVIRONMENT-NAME"
opsman_image_url = "YOUR-OPS-MAN-IMAGE-URL"
region       = "YOUR-GCP-REGION"
zones        = ["YOUR-AZ-1", "YOUR-AZ-2", "YOUR-AZ-3"]
project      = "YOUR-GCP-PROJECT"
dns_suffix    = "YOUR-DNS-SUFFIX"

ssl_cert = <<SSL_CERT
-----BEGIN CERTIFICATE-----
YOUR-CERTIFICATE
-----END CERTIFICATE-----
SSL_CERT

ssl_private_key = <<SSL_KEY
-----BEGIN EXAMPLE RSA PRIVATE KEY-----
YOUR-PRIVATE-KEY
-----END EXAMPLE RSA PRIVATE KEY-----
SSL_KEY

service_account_key = <<SERVICE_ACCOUNT_KEY
YOUR-KEY-JSON
SERVICE_ACCOUNT_KEY
```

9. Edit the values in the file according to the table below.

| Value to replace | Guidance |
|--|--|
| <code>YOUR-ENVIRONMENT-NAME</code> | Enter a name to use to identify resources in GCP. Terraform prepends the names of the resources it creates with this environment name. Example: <code>pcf</code> . |
| <code>YOUR-OPS-MAN-IMAGE-URL</code> | Enter the source URL of the Ops Manager image you want to boot. You can find this URL in the PDF included with the Ops Manager release on Pivotal Network . |
| <code>YOUR-GCP-REGION</code> | Enter the name of the GCP region in which you want Terraform to create resources. Example: <code>us-central1</code> . |
| <code>YOUR-AZ-1</code> <code>YOUR-AZ-2</code> <code>YOUR-AZ-3</code> | Enter three availability zones from your region. Example: <code>us-central1-a</code> , <code>us-central1-b</code> , <code>us-central1-c</code> . |
| <code>YOUR-GCP-PROJECT</code> | Enter the name of the GCP project in which you want Terraform to create resources. |
| <code>YOUR-DNS-SUFFIX</code> | Enter a domain name to use as part of the system domain for your PCF deployment. Terraform creates DNS records in GCP using <code>YOUR-ENVIRONMENT-NAME</code> and <code>YOUR-DNS-SUFFIX</code> . For example, if you enter <code>example.com</code> for your DNS suffix and have <code>pcf</code> as your environment name, Terraform creates DNS records at <code>pcf.example.com</code> . |
| <code>YOUR-CERTIFICATE</code> | Enter a certificate to use for HTTP load balancing. For production environments, use a certificate from a Certificate Authority (CA). For test environments, you can use a self-signed certificate. Your certificate must specify your system domain as the common name. Your system domain |

| | |
|-------------------------------|--|
| | is <code>YOUR-ENVIRONMENT-NAME.YOUR-DNS-SUFFIX</code> . It also must include the following subdomains: <code>*.sys.YOUR-SYSTEM-DOMAIN</code> , <code>*.login.sys.YOUR-SYSTEM-DOMAIN</code> , <code>*.uaa.sys.YOUR-SYSTEM-DOMAIN</code> , <code>*.apps.YOUR-SYSTEM-DOMAIN</code> . |
| <code>YOUR-PRIVATE-KEY</code> | Enter a private key for the certificate you entered. |
| <code>YOUR-KEY-JSON</code> | Enter the contents of your service account key file. This file is in JSON format. |

Step 3: Add Optional Variables

Complete this step if you want to do any of the following:

- Change the default CIDR ranges
- Deploy the Isolation Segment tile
- Use an external Google Cloud SQL database
- Use external Google Storage buckets
- Disable generated GCP service account key for blobstore

In your `terraform.tfvars` file, specify the appropriate variables from the sections below.

 **Note:** You can see the configurable options by opening the `variables.tf` file and looking for variables with default values.

CIDR Ranges for Subnets

If you want to change the CIDR ranges for the management, your runtime, or services networks that Terraform creates, add the following variables to your `terraform.tfvars` file, replacing `YOUR-MANAGEMENT-CIDR`, `YOUR-RUNTIME-CIDR` and `YOUR-SERVICES-CIDR` with your desired values.

```
management_cidr = YOUR-MANAGEMENT-CIDR
pas_cidr = YOUR-RUNTIME-CIDR
services_cidr = YOUR-SERVICES-CIDR
```

Isolation Segments

If you plan to deploy the Isolation Segment tile, add the following variables to your `terraform.tfvars` file, replacing `YOUR-CERTIFICATE` and `YOUR-PRIVATE-KEY` with a certificate and private key. This causes Terraform to create an additional HTTP load balancer across three availability zones to use for the Isolation Segment tile.

```
isolation_segment = true
iso_seg_ssl_cert = <<ISO_SEG_SSL_CERT
-----BEGIN CERTIFICATE-----
YOUR-CERTIFICATE
-----END CERTIFICATE-----
ISO_SEG_SSL_CERT
iso_seg_ssl_cert_private_key = <<ISO_SEG_SSL_KEY
-----BEGIN EXAMPLE RSA PRIVATE KEY-----
YOUR-PRIVATE-KEY
-----END EXAMPLE RSA PRIVATE KEY-----
ISO_SEG_SSL_KEY
```

External Database

1. If you want to use an external Google Cloud SQL database for Ops Manager and Pivotal Application Service (PAS), add the following to your `terraform.tfvars` file:

```
external_database = true
```

2. If you want to specify a single host from which users can connect to the Ops Manager and runtime databases, add the following to your `terraform.tfvars` file.

```
opsman_sql_db_host = HOST-IP-ADDRESS
pas_sql_db_host = HOST-IP-ADDRESS
```

Where `HOST-IP-ADDRESS` is your desired IP address(es).

External Storage Buckets

If you want to use Google Cloud Storage buckets for the PAS Cloud Controller, add the following to your `terraform.tfvars` file:

```
create_gcs_buckets = true
```

GCP Service Account Key for Blobstore

If you want to provide your own service account for blob storage instead of using a generated service account, add the following to your `terraform.tfvars` file:

```
create_blobstore_service_account_key = false
```

Step 4: Create GCP Resources with Terraform

Follow these steps to use the Terraform CLI to create resources on GCP:

1. From the directory that contains the Terraform files, run the following command to initialize the directory based on the information you specified in the `terraform.tfvars` file.

```
terraform init
```

2. Run the following command to create the execution plan for Terraform.

```
terraform plan -out=plan
```

3. To execute the plan from the previous step, run the following command:

```
terraform apply plan
```

Note: It may take several minutes for Terraform to create all the resources in GCP.

Step 5: Create DNS Record

1. In a browser, navigate to the DNS provider for the DNS suffix you entered in your `terraform.tfvars` file.
2. Create a new NS (Name server) record for your PCF system domain. Your system domain is `YOUR-ENVIRONMENT-NAME.YOUR-DNS-SUFFIX`.
 - a. In this record, enter the name servers included in `env_dns_zone_name_servers` from your Terraform output.

Next Steps

After you complete this procedure, follow the instructions in the [Configuring BOSH Director on GCP Using Terraform](#) topic.

Configuring BOSH Director on GCP Using Terraform

Page last updated:

This topic describes how to configure the BOSH Director for Pivotal Cloud Foundry (PCF) on Google Cloud Platform (GCP) after [Preparing to Deploy Ops Manager on GCP Using Terraform](#).

Note: You can also perform the procedures in this topic using the Ops Manager API. For more information, see the [Using the Ops Manager API](#) topic.

Prerequisite

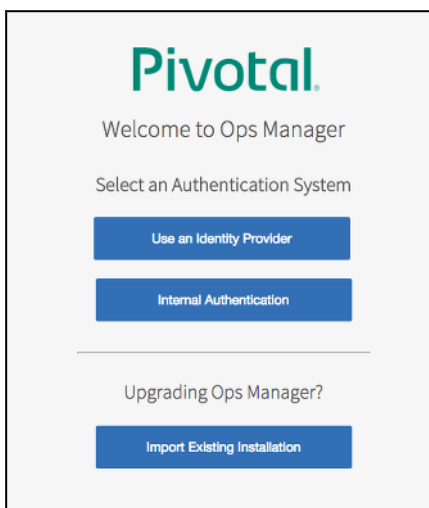

To complete the procedures in this topic, you must have access to the output from when you ran `terraform apply` to create resources for this deployment. You can view this output at any time by running `terraform output`. You use the values in your Terraform output to configure the BOSH Director tile.

Step 1: Access Ops Manager

1. In a web browser, navigate to the fully qualified domain name (FQDN) of the BOSH Director. Use the `ops_manager_dns` value from running `terraform output`.

Note: In order to set up Ops Manager authentication correctly, Pivotal recommends using a Fully Qualified Domain Name (FQDN) to access Ops Manager. Using an ephemeral IP address to access Ops Manager can cause authentication errors upon subsequent access.

2. When Ops Manager starts for the first time, you must choose one of the following:
 - [Use an Identity Provider](#): If you use an Identity Provider, an external identity server maintains your user database.
 - [Internal Authentication](#): If you use Internal Authentication, Ops Manager maintains your user database.

Use an Identity Provider (IdP)

1. Log in to your IdP console and download the IdP metadata XML. Optionally, if your IdP supports metadata URL, you can copy the metadata URL instead of the XML.

2. Copy the IdP metadata XML or URL to the Ops Manager **Use an Identity Provider** login page.

Note: The same IdP metadata URL or XML is applied for the BOSH Director. If you use a separate IdP for BOSH, copy the metadata XML or URL from that IdP and enter it into the BOSH IdP Metadata text box in the Ops Manager login page.

3. Enter values for the fields listed below. Failure to provide values in these fields results in a `500` error.

Note: These attributes are case-sensitive.

- **SAML admin group:** Enter the name of the SAML group that contains all Ops Manager administrators.
- **SAML groups attribute:** Enter the groups attribute tag name with which you configured the SAML server.

4. Enter your **Decryption passphrase**. Read the **End User License Agreement**, and select the checkbox to accept the terms.

5. Your Ops Manager login page appears. Enter your username and password. Click **Login**.

6. Download your SAML Service Provider metadata (SAML Relying Party metadata) by navigating to the following URLs:

- **6a.** Ops Manager SAML service provider metadata: `https://OPS-MAN-FQDN:443/uaa/saml/metadata`
- **6b.** BOSH Director SAML service provider metadata: `https://BOSH-IP-ADDRESS:8443/saml/metadata`

Note: To retrieve your `BOSH-IP-ADDRESS`, navigate to the **BOSH Director** tile > **Status** tab. Record the **BOSH Director** IP address.

7. Configure your IdP with your SAML Service Provider metadata. Import the Ops Manager SAML provider metadata from Step 6a above to your IdP. If your IdP does not support importing, provide the values below.

- **Single sign on URL:** `https://OPS-MAN-FQDN:443/uaa/saml/SSO/alias/OPS-MAN-FQDN`
- **Audience URI (SP Entity ID):** `https://OP-MAN-FQDN:443/uaa`
- **Name ID:** Email Address
- SAML authentication requests are always signed

8. Import the BOSH Director SAML provider metadata from Step 6b to your IdP. If the IdP does not support an import, provide the values below.

- **Single sign on URL:** `https://BOSH-IP:8443/saml/SSO/alias/BOSH-IP`
- **Audience URI (SP Entity ID):** `https://BOSH-IP:8443`
- **Name ID:** Email Address
- SAML authentication requests are always signed

9. Return to the **BOSH Director** tile, and continue with the configuration steps below.

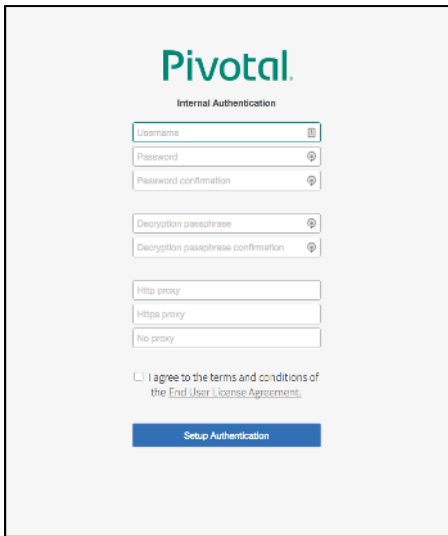

Internal Authentication

1. When redirected to the **Internal Authentication** page, do the following:

- Enter a **Username**, **Password**, and **Password confirmation** to create an Admin user.
- Enter a **Decryption passphrase** and the **Decryption passphrase confirmation**. This passphrase encrypts the Ops Manager datastore, and is not

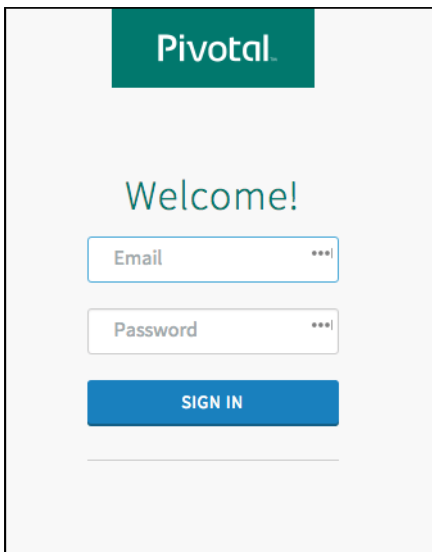

recoverable if lost.

- If you are using an **HTTP proxy** or **HTTPS proxy**, follow the instructions in the [Configuring Proxy Settings for the BOSH CPI](#) topic.
- Read the **End User License Agreement**, and select the checkbox to accept the terms.
- Click **Setup Authentication**.

The image shows the 'Pivotal Internal Authentication' setup form. It includes fields for Username, Password, Password confirmation, Decryption passphrase, and Decryption passphrase confirmation. There are also fields for Http proxy, Https proxy, and No proxy. A checkbox for 'I agree to the terms and conditions of the End User License Agreement' is present, followed by a 'Setup Authentication' button.

2. Log in to Ops Manager with the Admin username and password that you created in the previous step.

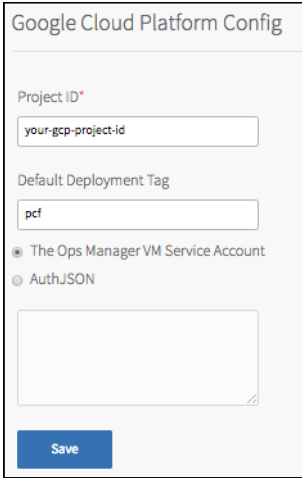

The image shows the 'Pivotal Welcome!' login form. It features a 'Pivotal' logo at the top, followed by a 'Welcome!' message. Below this are input fields for 'Email' and 'Password', both with masked characters (***). A blue 'SIGN IN' button is positioned below the password field.

Step 2: Google Cloud Platform Config

1. Click the **Google Cloud Platform** tile within the **Installation Dashboard**.
2. Select **Google Config**. Complete the following fields:
 - **Project ID**: Enter the value of `project` from your `terraform.tfvars` file.
 - **Default Deployment Tag**: Enter the value of `env_name` from your `terraform.tfvars` file.
 - Select **AuthJSON** and in the field below enter the contents of the JSON file for your service account key.

 **Note:** As an alternative, you can select **The Ops Manager VM Service Account** option to use the service account automatically created by GCP for the Ops Manager VM.

3. Click **Save**.

Step 3: Director Config Page

1. Select **Director Config** to open the **Director Config** page.

2. In the **NTP Servers (comma delimited)** field, enter `metadata.google.internal`.

 **Note:** To resolve `metadata.google.internal` as the NTP server hostname, you must provide the two IP addresses for DNS configuration as described in [Step 5: Create Networks Page](#) of this procedure.

 **Note:** The NTP server configuration only updates after VM recreation. Ensure that you select the **Recreate all VMs** checkbox if you modify

the value of this field.

3. Leave the **JMX Provider IP Address** field blank.

 **Note:** Starting from PCF v2.0, BOSH-reported component metrics are available in the Loggregator Firehose by default. Therefore, if you continue to use PCF JMX Bridge for consuming them outside of the Firehose, you may receive duplicate data. To prevent this, leave the **JMX Provider IP Address** field blank. For additional guidance, see [BOSH System Metrics Available in Loggregator Firehose](#).

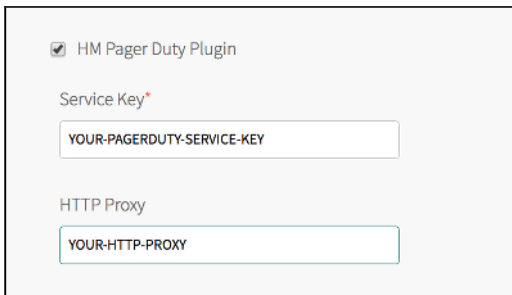

4. Leave the **Bosh HM Forwarder IP Address** field blank.

 **Note:** Starting from PCF v2.0, BOSH-reported component metrics are available in the Loggregator Firehose by default. Therefore, if you continue to use the BOSH HM Forwarder for consuming them, you may receive duplicate data. To prevent this, leave the **Bosh HM Forwarder IP Address** field blank. For additional guidance, see [BOSH System Metrics Available in Loggregator Firehose](#).

5. Select the **Enable VM Resurrector Plugin** checkbox to enable the Ops Manager Resurrector functionality and increase Pivotal Application Service (PAS) availability.
6. (Optional) Select **Enable Post Deploy Scripts** to run a post-deploy script after deployment. This script allows the job to execute additional commands against a deployment.

 **Note:** You must enable post-deploy scripts to install PKS.

7. (Optional) Select **Recreate all VMs** to force BOSH to recreate all VMs on the next deploy. This process does not destroy any persistent disk data.
8. Select **Enable bosh deploy retries** for Ops Manager to retry failed BOSH operations up to five times.
9. (Optional) Disable **Allow Legacy Agents** if all of your tiles have stemcells v3468 or later. Disabling the field will allow Ops Manager to implement TLS secure communications.
10. (Optional) Select **Keep Unreachable Director VMs** if you want to preserve BOSH Director VMs after a failed deployment for troubleshooting purposes.
11. (Optional) Select **HM Pager Duty Plugin** to enable Health Monitor integration with PagerDuty.

☒ HM Pager Duty Plugin

Service Key*

YOUR-PAGERDUTY-SERVICE-KEY

HTTP Proxy

YOUR-HTTP-PROXY

- **Service Key:** Enter your API service key from PagerDuty.
- **HTTP Proxy:** Enter an HTTP proxy for use with PagerDuty.

☒ **HM Email Plugin**

Host*

Port*

Domain*

From*

Recipients*

Username

Password

☒ **Enable TLS**

12. (Optional) Select **HM Email Plugin** to enable Health Monitor integration with email.

- **Host:** Enter your email hostname.
- **Port:** Enter your email port number.
- **Domain:** Enter your domain.
- **From:** Enter the address for the sender.
- **Recipients:** Enter comma-separated addresses of intended recipients.
- **Username:** Enter the username for your email server.
- **Password:** Enter the password for your email server.
- **Enable TLS:** Select this checkbox to enable Transport Layer Security.

13. For **CredHub Encryption Provider**, you can choose whether BOSH CredHub stores its encryption key internally on the BOSH Director and CredHub VM, or in an external hardware security module (HSM). The HSM option is more secure.

Before configuring an HSM encryption provider in the **Director Config** pane, you must follow the procedures and collect information described in [Preparing CredHub HSMs for Configuration](#).

 **Note:** After you deploy Ops Manager with an HSM encryption provider, you cannot change BOSH CredHub to store encryption keys internally.

CredHub Encryption Provider

☒ Internal
 ☐ Luna HSM

Encryption Key Name*

Provider Partition*

Provider Partition Password*

Provider Client Certificate*

Provider Client Certificate Private Key*

HSM Host Address*

HSM Port Address*

Partition Serial Number*

HSM Certificate*

- **Internal:** Select this option for internal CredHub key storage. This option is selected by default and requires no additional configuration.
- **Luna HSM:** Select this option to use a SafeNet Luna HSM as your permanent CredHub encryption provider, and fill in the following fields:
 1. **Encryption Key Name:** Any name to identify the key that the HSM uses to encrypt and decrypt the CredHub data. Changing this key name after you deploy Ops Manager can cause service downtime.
 2. **Provider Partition:** The partition that stores your encryption key. Changing this partition after you deploy Ops Manager could cause service downtime. For this value and the ones below, use values gathered in [Preparing CredHub HSMs for Configuration](#).
 3. **Provider Partition Password**
 4. **Provider Client Certificate:** The certificate that validates the identity of the HSM when CredHub connects as a client.
 5. **Provider Client Certificate Private Key**
 6. **HSM Host Address**
 7. **HSM Port Address:** If you do not know your port address, enter `1792`.
 8. **Partition Serial Number**
 9. **HSM Certificate:** The certificate that the HSM presents to CredHub to establish a two-way mTLS connection.

14. Select a **Blobstore Location** to either configure the blobstore as an internal server or an external endpoint. Because the internal server is unscalable and less secure, Pivotal recommends that you configure an external blobstore.

 **Note:** After you deploy Ops Manager, you cannot change the blobstore location.

Blobstore Location

☒ Internal
☐ S3 Compatible Blobstore

S3 Endpoint*

Bucket Name*

Access Key*

Secret Key*

☒ V2 Signature
☐ V4 Signature

Region*

☐ GCS Blobstore

Bucket Name*

Storage Class*

Regional

Service Account Key*

- o **Internal:** Select this option to use an internal blobstore. Ops Manager creates a new VM for blob storage. No additional configuration is required.
- o **S3 Compatible Blobstore:** Select this option to use an external S3-compatible endpoint. Follow the procedures in [Sign up for Amazon S3](#) and [Creating a Bucket](#) in the AWS documentation. When you have created an S3 bucket, complete the following steps:
 1. **S3 Endpoint:** Navigate to the [Regions and Endpoints](#) topic in the AWS documentation.
 - a. Locate the endpoint for your region in the **Amazon Simple Storage Service (S3)** table and construct a URL using your region's endpoint. For example, if you are using the `us-west-2` region, the URL you create would be `https://s3-us-west-2.amazonaws.com`. Enter this URL into the **S3 Endpoint** field.
 - b. On a command line, run `ssh ubuntu@OPS-MANAGER-FQDN` to SSH into the Ops Manager VM. Replace `OPS-MANAGER-FQDN` with the fully qualified domain name of Ops Manager.
 - c. Copy the custom public CA certificate you used to sign the S3 endpoint into `/etc/ssl/certs` on the Ops Manager VM.
 - d. On the Ops Manager VM, run `sudo update-ca-certificates -f -v` to import the custom CA certificate into the Ops Manager VM truststore.

 **Note:** You must also add this custom CA certificate into the **Trusted Certificates** field in the **Security** page. See [Security Page](#) for instructions.

2. **Bucket Name:** Enter the name of the S3 bucket.
3. **Access Key** and **Secret Key:** Enter the keys you generated when creating your S3 bucket.
4. Select **V2 Signature** or **V4 Signature**. If you select **V4 Signature**, enter your **Region**.

 **Note:** AWS recommends using Signature Version 4. For more information about AWS S3 Signatures, see [Authenticating Requests](#) in the AWS documentation.

- **Enable TLS:** Select this checkbox to enable TLS.

 **Note:** If you are using Linux stemcells, make sure you have configured [Linux stemcell v3586.16 or later](#) for all tiles before enabling TLS.

 **Note:** If you are using PAS for Windows 2016, make sure you have configured [Windows stemcell v1709.10 or later](#) for all tiles before enabling TLS.

- **GCS Blobstore:** Select this option to use an external Google Cloud Storage (GCS) endpoint. To create a GCS bucket, follow the procedures in [Creating Storage Buckets](#) in the GCS documentation. When you have created a GCS bucket, complete the following steps:
 1. **Bucket Name:** Enter the name of your GCS bucket.
 2. **Storage Class:** Select the storage class for your GCS bucket. See [Storage Classes](#) in the GCP documentation for more information.
 3. **Service Account Key:** Enter the contents of the JSON file that you downloaded in the [Set up an IAM Service Account](#) section of *Preparing to Deploy Ops Manager on GCP Manually*.

15. For **Database Location**, if you configured your `terraform.tfvars` file to create an external database for Ops Manager, select **External MySQL Database** and complete the fields below. Otherwise, select **Internal**.

- **Host:** Enter the value of `sql_db_ip` from your Terraform output.
- **Port:** Enter `3306`.
- **Username:** Enter the value of `opsman_sql_username` from your Terraform output.
- **Password:** Enter the value of `opsman_sql_password` from your Terraform output.
- **Database:** Enter the value of `opsman_sql_db_name` from your Terraform output.

In addition, if you selected **External MySQL Database**, you can fill out the following optional fields:

- **Enable TLS:** Selecting this checkbox enables TLS communication between the BOSH Director and the database.
- **TLS CA:** Enter the Certificate Authority for the TLS Certificate.
- **TLS Certificate:** Enter the client certificate for mutual TLS connections to the database.
- **TLS Private Key:** Enter the client private key for mutual TLS connections to the database.
- **Advanced DB Connection Options:** If you would like to provide additional options for the database, use this field to provide a JSON-formatted options string.

 **Note:** You must select **Enable TLS for Director Database** to configure the TLS-related fields.

16. (Optional) Modify the **Director Workers** value, which sets the number of workers available to execute Director tasks. This field defaults to `5`.
17. (Optional) **Max Threads** sets the maximum number of threads that the BOSH Director can run simultaneously. Pivotal recommends that you leave the field blank to use the default value, unless doing so results in rate limiting or errors on your IaaS.
18. (Optional) To add a custom URL for your BOSH Director, enter a valid hostname in **Director Hostname**. You can also use this field to configure [a load balancer in front of your BOSH Director](#).

 **warning:** In Ops Manager v2.2.7 and earlier, if you change the **Director Hostname** after your initial deployment, VMs become unavailable. This causes PCF downtime. To restore VM availability, enable **Recreate All VMs** and redeploy. This issue is resolved in [Ops Manager v2.2.8](#) and later.

Director Workers

5

Max Threads

Director Hostname

opsdirector.example.com

19. (Optional) Enter your list of comma-separated **Excluded Recursors** to declare which IP addresses and ports should not be used by the DNS server.
20. (Optional) To disable BOSH DNS, select the **Disable BOSH DNS server for troubleshooting purposes** checkbox. For more information about the BOSH DNS service discovery mechanism, see [BOSH DNS Enabled by Default](#) in the Ops Manager v2.2 Release Notes.

 **Note:** Disabling BOSH DNS affects [Step 5: Create Networks Page](#) below when you configure your network DNS. You must first navigate to your PAS tile and enter `8.8.8.8` into the **DNS Servers** field.

 **Breaking Change:** Do not disable BOSH DNS without consulting Pivotal Support.

21. (Optional) To set a custom banner that users see when logging in to the Director using SSH, enter text in the **Custom SSH Banner** field.

☐ Disable BOSH DNS server for troubleshooting purposes

Custom SSH Banner

22. (Optional) Enter your comma-separated custom **Identification Tags**. For example, `iaas:foundation1,hello:world`. You can use the tags to identify your foundation when viewing VMs or disks from your IaaS.
23. Click **Save**.

Step 4: Create Availability Zones Page

 **Note:** Pivotal recommends at least three availability zones for a highly available installation of PAS. For an example of a three availability zone deployment, see [Reference Architecture for Pivotal Cloud Foundry on GCP](#).

1. Select **Create Availability Zones**.
2. Use the **Add** button to add three availability zones corresponding to those listed in the `azs` field in your Terraform output.
3. Click **Save**.

Step 5: Create Networks Page

1. Select **Create Networks**.
2. Make sure **Enable ICMP checks** is not selected. GCP routers do not respond to ICMP pings.

- Use the **Add Network** button to create the following three networks:

 **Note:** To use a shared VPC network, enter the shared VPC host project name before the network name in the format `VPC-PROJECT-NAME/NETWORK-NAME/SUBNET-NAME/REGION-NAME`. For example, `vpc-project/opsmgr/central/us-central1`. For more information, see [Configuring a Shared VPC on GCP](#).

 **Note:** If you disabled BOSH DNS, enter `8.8.8.8` into the **DNS Servers** field of the PAS tile. For more information, see step 29g in the *Configure Networking* section of the [Deploying PAS on GCP Using Terraform](#) topic.

Infrastructure Network

| | |
|---------------------|---|
| Network Name | infrastructure |
| Google Network Name | Use the <code>network_name</code> , <code>infrastructure_subnet_name</code> , and <code>region</code> fields from your Terraform output to enter the name of the infrastructure network created by Terraform. The format is: <code>network_name/infrastructure_subnet_name/region</code> |
| CIDR | Enter the value of <code>infrastructure_subnet_cidrs</code> from your Terraform output. |
| Reserved IP Ranges | Enter the first <code>.1</code> through <code>.9</code> addresses from the CIDR. For example, if the CIDR is <code>192.168.101.0/26</code> , enter the range <code>192.168.101.1-192.168.101.9</code> . |
| DNS | 169.254.169.254 |
| Gateway | Enter the value of <code>infrastructure_subnet_gateway</code> from your Terraform output. |
| Availability Zones | Select all three availability zones. |

Runtime Network

| | |
|---------------------|--|
| Network Name | pas |
| Google Network Name | Use the <code>network_name</code> , <code>pas_subnet_name</code> , and <code>region</code> fields from your Terraform output to enter the name of the PAS network created by Terraform. The format is: <code>network_name/pas_subnet_name/region</code> |
| CIDR | Enter the value of <code>pas_subnet_cidrs</code> from your Terraform output. |
| Reserved IP Ranges | Enter the first <code>.1</code> through <code>.9</code> addresses from the CIDR. For example, if the CIDR is <code>192.168.16.0/22</code> , enter the range <code>192.168.16.1-192.168.16.9</code> . |
| DNS | 169.254.169.254 |
| Gateway | Enter the value of <code>pas_subnet_gateway</code> from your Terraform output. |
| Availability Zones | Select all three availability zones. |

Services Network

| | |
|---------------------|---|
| Network Name | services |
| Google Network Name | Use the <code>network_name</code> , <code>services_subnet_name</code> , and <code>region</code> fields from your Terraform output to enter the name of the services network created by Terraform. The format is: <code>network_name/services_subnet_name/region</code> |
| CIDR | Enter the value of <code>services_subnet_cidrs</code> from your Terraform output. |
| Reserved IP Ranges | Enter the first <code>.1</code> through <code>.9</code> addresses from the CIDR. For example, if the CIDR is <code>192.168.16.0/22</code> , enter the range <code>192.168.20.1-192.168.20.9</code> . |
| DNS | 169.254.169.254 |
| Gateway | Enter the value of <code>services_subnet_gateway</code> from your Terraform output. |
| Availability Zones | Select all three availability zones. |

Note: After you deploy Ops Manager, you add subnets with overlapping Availability Zones to expand your network. For more information about configuring additional subnets, see [Expanding Your Network with Additional Subnets](#).

Step 6: Assign AZs and Networks Page

1. Select **Assign AZs and Networks**.
2. Use the dropdown to select a **Singleton Availability Zone**. The BOSH Director installs in this Availability Zone.
3. Under **Network**, select the **infrastructure** network for your BOSH Director.
4. Click **Save**.

Step 7: Security Page

Security

Trusted Certificates

-----BEGIN CERTIFICATE-----

THE-----

-----END CERTIFICATE-----

These certificates enable BOSH-deployed components to trust a custom root certificate.

Generate VM passwords or use single password for all VMs

☒ Generate passwords
 ☐ Use default BOSH password

Save

1. Select **Security**.
2. In **Trusted Certificates**, enter your custom certificate authority (CA) certificates to insert into your organization's certificate trust chain. This feature enables all BOSH-deployed components in your deployment to trust custom root certificates.

To enter multiple certificates, paste your certificates one after the other. For example, format your certificates like the following:

```
-----BEGIN CERTIFICATE-----
ABCDEF12345678ABCDEF12345678ABCDEF12345678AB
EFGH12345678ABCDEF12345678ABCDEF12345678ABCDEF
GH12345678ABCDEF12345678ABCDEF12345678...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
BCDEF12345678ABCDEF12345678ABCDEF12345678ABB
EFGH12345678ABCDEF12345678ABCDEF12345678ABCDEF
GH12345678ABCDEF12345678ABCDEF12345678...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
CDEF12345678ABCDEF12345678ABCDEF12345678ABBB
EFGH12345678ABCDEF12345678ABCDEF12345678ABCDEF
GH12345678ABCDEF12345678ABCDEF12345678...
-----END CERTIFICATE-----
```

Note: If you want to use Docker Registries for running app instances in Docker containers, enter the certificate for your private Docker Registry in this field. See [Using Docker Registries](#) for more information on running app instances in PAS using Docker Registries.

3. Choose **Generate passwords** or **Use default BOSH password**. Pivotal recommends that you use the **Generate passwords** option for greater security.
4. Click **Save**. To view your saved Director password, click the **Credentials** tab.

Step 8: Syslog Page

1. Select **Syslog**.

Syslog

Do you want to configure Syslog for Bosh Director?

☐ No
☒ Yes

Address*

The address or host for the syslog server

Port*

Transport Protocol*

TCP

⌵

☐ Enable TLS

Permitted Peer*

SSL Certificate*

Save

2. (Optional) Select **Yes** to send BOSH Director system logs to a remote server.
3. In the **Address** field, enter the IP address or DNS name for the remote server.
4. In the **Port** field, enter the port number that the remote server listens on.
5. In the **Transport Protocol** dropdown menu, select **TCP**, **UDP**, or **REL**P. This selection determines which transport protocol is used to send the logs to the remote server.
6. (Optional) Pivotal strongly recommends that you enable TLS encryption when forwarding logs as they may contain sensitive information. For example, these logs may contain cloud provider credentials. To enable TLS, perform the following steps.
 - In the **Permitted Peer** field, enter either the name or SHA1 fingerprint of the remote peer.

- In the **SSL Certificate** field, enter the SSL certificate for the remote server.

7. Click **Save**.

Step 9: Resource Config Page

1. Select **Resource Config**.
2. Verify that the **Internet Connected** checkbox for every job is checked. The Terraform templates do not provision a Network Address Translation (NAT) box for Internet connectivity to your VMs so instead they will be provided with ephemeral public IP addresses to allow the jobs to reach the Internet.

 **Note:** If you want to provision a Network Address Translation (NAT) box to provide Internet connectivity to your VMs instead of providing them with public IP addresses, deselect the **Internet Connected** checkboxes. For more information about using NAT in GCP, see the [GCP documentation](#).

 **Note:** If you install PAS for Windows, provision your **Master Compilation Job** with at least 100 GB of disk space.

Step 10: (Optional) Add Custom VM Extensions

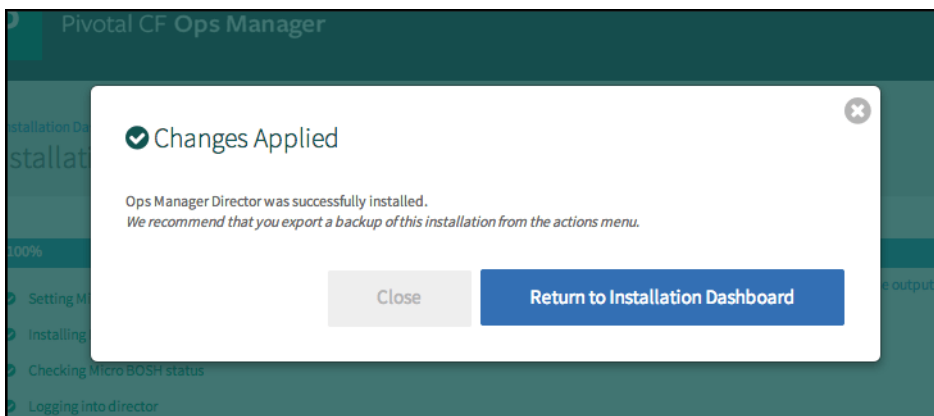

Use the Ops Manager API to add custom properties to your VMs such as associated security groups and load balancers. For more information, see [Managing Custom VM Extensions](#).

Step 11: Complete the BOSH Director Installation

1. Click the **Installation Dashboard** link to return to the Installation Dashboard.
2. Click **Apply Changes**. If the following ICMP error message appears, return to the [Network Config](#) screen, and make sure you have deselected the **Enable ICMP Checks** box. Then click **Apply Changes** again.

3. BOSH Director installs. This may take a few moments. When the installation process successfully completes, the **Changes Applied** window appears.

What to Do Next

After you complete this procedure, follow the instructions in the [Deploying PAS on GCP](#) topic.

Deploying PAS on GCP Using Terraform

Page last updated:

This topic describes how to install and configure Pivotal Application Service (PAS) on Google Cloud Platform (GCP).

Before beginning this procedure, ensure that you have successfully completed the [Configuring BOSH Director on GCP Using Terraform](#) topic.

Note: If you plan to [install the PCF IPsec add-on](#), you must do so before installing any other tiles. Pivotal recommends installing IPsec immediately after Ops Manager, and before installing the PAS tile.

Prerequisite

To complete the procedures in this topic, you must have access to the output from when you ran `terraform apply` to create resources for this deployment. You can view this output at any time by running `terraform output`. You use the values in your Terraform output to configure the BOSH Director tile.

Step 1: Download the PAS Tile

1. If you have not already downloaded PAS, log in to [Pivotal Network](#), and click on **Pivotal Application Service**.
2. From the **Releases** dropdown, select the release to install and choose one of the following:
 - a. Click **Pivotal Application Service** to download the PAS `.pivotal` file.
 - b. Click **PCF Small Footprint Runtime** to download the Small Footprint Runtime `.pivotal` file. For more information, see [Getting Started with Small Footprint Runtime](#).

Step 2: Add PAS to Ops Manager

1. Navigate to the Pivotal Cloud Foundry Operations Manager Installation Dashboard.
2. Click **Import a Product** to add the PAS tile to Ops Manager. This may take a while depending on your connection speed.

Note: After you import a tile to Ops Manager, you can view the latest available version of that tile in the Installation Dashboard by enabling the Pivotal Network API. For more information, refer to the [Adding and Deleting Products](#) topic.

3. On the left, click the plus icon next to the imported PAS product to add it to the Installation Dashboard.
4. Click the newly added PAS tile in the Installation Dashboard.

Step 3: Assign Availability Zones and Networks

1. Select **Assign AZ and Networks**. These are the Availability Zones that you [create](#) when configuring BOSH Director.
2. Select the first Availability Zone under **Place singleton jobs**. Ops Manager runs any job with a single instance in this Availability Zone.
3. Select all Availability Zones under **Balance other jobs**. Ops Manager balances instances of jobs with more than one instance across the Availability Zones that you specify.

Note: For production deployments, Pivotal recommends at least three Availability Zones for a highly available installation of PAS.

4. From the **Network** dropdown, choose the network you created in [Step 5: Create Networks Page](#) of the *Configuring BOSH Director on GCP Using Terraform* topic.
5. Click **Save**.

Step 5: Configure Domains

1. Select **Domains**.

Application Service hosts applications at subdomains under its apps domain and assigns system components to subdomains under its system domain. You need to configure a wildcard DNS for both the apps domain and system domain. The two domains can be the same, although this is not recommended.

System Domain *

Apps Domain *

Save

2. Enter the system and application domains that were created by Terraform:
 - **System Domain:** Enter the value of `sys_domain` from your Terraform output.
 - **Apps Domain:** Enter the value of `apps_domain` from your Terraform output.
3. Click **Save**.

Step 6: Configure Networking

1. Select **Networking**.
2. Leave the **Router IPs**, **SSH Proxy IPs**, **HAProxy IPs**, and **TCP Router IPs** fields blank. You do not need to complete these fields when deploying PCF to GCP.

Note: You specify load balancers in the **Resource Config** section of PAS later on in the installation process. See the [Configure Load Balancers](#) section of this topic for more information.

3. Under **Certificates and Private Keys for HAProxy and Router**, you must provide an **SSL Certificate and Private Key**. Starting in PCF v.1.12, HAProxy and the Gorouter are enabled to receive TLS communication by default.

Certificates and Private Keys for HAProxy and Router

Add

▼ example-cert

Name *

example-cert

A human-readable name describing the use of this certificate.

Certificate and Private Key for HAProxy and Router *

-----BEGIN CERTIFICATE-----

MIIE...

-----END RSA PRIVATE KEY-----

Generate RSA Certificate

▼ example-cert-2

Name *

example-cert-2

Certificate and Private Key for HAProxy and Router *

-----BEGIN CERTIFICATE-----

MIIE...

-----END RSA PRIVATE KEY-----

You can either provide a certificate signed by a Certificate Authority (CA) or click on the **Generate RSA Certificate** link to generate a self-signed certificate in Ops Manager. Ensure the certificate includes `*.YOUR-SYSTEM-DOMAIN`, `*.apps.YOUR-SYSTEM-DOMAIN`, and `*.sys.YOUR-SYSTEM-DOMAIN`.

For details about generating certificates in Ops Manager for your wildcard system domains, see [Providing a Certificate for Your SSL/TLS Termination Point](#).

 **Note:** Ensure that you add any certificates that you generate in this pane to your infrastructure load balancer.

- (Optional) When validating client requests using mutual TLS, the Gorouter trusts multiple certificate authorities (CAs) by default. If you want to configure the Gorouter and HAProxy to trust additional CAs, enter your CA certificates under **Certificate Authorities Trusted by Router and HAProxy**. All CA certificates should be appended together into a single collection of PEM-encoded entries.

Certificate Authorities Trusted by Router and HAProxy

In addition to well-known, public CAs, and those trusted via the BOSH trusted certificates collection, these certificates can be used to validate the certificates from incoming client requests. All CA certificates should be appended together into a single collection of PEM-encoded entries.

- In the **Minimum version of TLS supported by HAProxy and Router** field, select the minimum version of TLS to use in HAProxy and Gorouter communications. HAProxy and Gorouter use TLS v1.2 by default. If you need to accommodate clients that use an older version of TLS, select a lower

minimum version. For a list of TLS ciphers supported by the Gorouter, see [Securing Traffic into Cloud Foundry](#).

Minimum version of TLS supported by HAProxy and Router*

- ☐ TLSv1.0
- ☐ TLSv1.1
- ☒ TLSv1.2

6. Configure **Logging of Client IPs in CF Router**. The **Log client IPs** option is set by default. To comply with the General Data Protection Regulation (GDPR), select one of the following options to disable logging of client IP addresses:

- If your load balancer exposes its own source IP address, disable logging of the `X-Forwarded-For` HTTP header only.
- If your load balancer exposes the source IP of the originating client, disable logging of both the source IP address and the `X-Forwarded-For` HTTP header.

Logging of Client IPs in CF Router*

- ☒ Log client IPs
 - ☐ Disable logging of X-Forwarded-For header only
 - ☐ Disable logging of both source IP and X-Forwarded-For header
- To comply with GDPR, select one of the options to disable logging of client IPs. If the source IP exposed by your load balancer is its own, choose to disable logging of XFF header only. If the source IP exposed by your load balancer is that of the downstream client, choose to disable logging of the source IP also.

7. Under **Configure support for the X-Forwarded-Client-Cert header**, configure PCF handles `x-forwarded-client-cert` (XFCC) HTTP headers based on where TLS is terminated for the first time in your deployment.

Configure support for the X-Forwarded-Client-Cert header. This header can be used by applications to verify the requester via mutual TLS. The option you should select depends upon where you will be terminating the TLS connection for the first time. *

- ☒ TLS terminated for the first time at infrastructure load balancer
- ☐ TLS terminated for the first time at HAProxy
- ☐ TLS terminated for the first time at the Router

The following table

indicates which option to choose based on your deployment layout.

| If your deployment is configured as follows: | Then select the following option: | Additional notes: |
|--|--|---|
| <ul style="list-style-type: none"> ◦ The Load Balancer is terminating TLS, and ◦ Load balancer is configured to put the client certificate from a mutual authentication TLS handshake into the X-Forwarded-Client-Cert HTTP header | TLS terminated for the first time at infrastructure load balancer (default). | Both HAProxy and the Gorouter forward the XFCC header when included in the request. |
| <ul style="list-style-type: none"> ◦ The Load Balancer is configured to pass through the TLS handshake via TCP to the instances of HAProxy, and ◦ HAProxy instance count is > 0 | TLS terminated for the first time at HAProxy. | HAProxy sets the XFCC header with the client certificate received in the TLS handshake. The Gorouter forwards the header. <div>  Breaking Change: In the Router behavior for Client Certificates field, you cannot select the Router does not request client certificates option. </div> |
| <ul style="list-style-type: none"> ◦ The Load Balancer is configured to pass through the TLS handshake via TCP to instances of the Gorouter | TLS terminated for the first time at the Gorouter. | The Gorouter strips the XFCC header if it is included in the request and forwards the client certificate received in the TLS handshake in a new XFCC header. <p>If you have deployed instances of HAProxy, app traffic bypasses those instances in this configuration. If you have also configured your load balancer to route requests for ssh directly to the Diego Brain, consider reducing HAProxy instances to 0.</p> <div>  Breaking Change: In the Router behavior for Client Certificates field, you cannot select the Router does not request client certificates option. </div> |

For a description of the behavior of each configuration option, see [Forward Client Certificate to Applications](#).

8. To configure HAProxy to handle client certificates, select one of the following options in the **HAProxy behavior for Client Certificate Validation** field.

HAProxy behavior for Client Certificate Validation*

- ☒ HAProxy does not request client certificates.
- ☐ HAProxy requests but does not require client certificates. This option is necessary if you want to enable mTLS for applications and TLS is terminated for the first time at HAProxy

- **HAProxy does not request client certificates.** This option requires mutual authentication, which makes it incompatible with XFCC option **TLS terminated for the first time at HAProxy**. HAProxy does not request client certificates, so the client does not provide them and no validation occurs. This is the default configuration.
- **HAProxy requests but does not require client certificates.** The HAProxy requests client certificates in TLS handshakes, validates them when presented, but does not require them.

⚠ warning: Upon upgrade, PAS will fail to receive requests if your load balancer is configured to present a client certificate in the TLS handshake with HAProxy but HAProxy has not been configured with the certificate authority used to sign it. To mitigate this issue, select **HAProxy does not request client certificates** in the **Networking** pane or configure the HAProxy with the appropriate CA.

9. To configure Gorouter behavior for handling client certificates, select one of the following options in the **Router behavior for Client Certificate Validation** field.

Router behavior for Client Certificate Validation*

- ☐ Router does not request client certificates. This option is incompatible with XFCC options "TLS terminated for the first time at HAProxy" and "TLS terminated for the first time at the Router" because these options require mutual authentication.
- ☒ Router requests but does not require client certificates.
- ☐ Router requires client certificates.

- **Router does not request client certificates.** This option is incompatible with the XFCC configuration options **TLS terminated for the first time at HAProxy** and **TLS terminated for the first time at the Router** in PAS because these options require mutual authentication. As client certificates are not requested, client will not provide them, and thus validation of client certificates will not occur.
- **Router requests but does not require client certificates.** The Gorouter requests client certificates in TLS handshakes, validates them when presented, but does not require them. This is the default configuration.
- **Router requires client certificates.** The Gorouter validates that the client certificate is signed by a Certificate Authority that the Gorouter trusts. If the Gorouter cannot validate the client certificate, the TLS handshake fails.

⚠ warning: Requests to the platform will fail upon upgrade if your load balancer is configured with client certificates and the Gorouter does not have the certificate authority. To mitigate this issue, select **Router does not request client certificates** for **Router behavior for Client Certificate Validation** in the **Networking** pane.

10. In the **TLS Cipher Suites for Router** field, review the TLS cipher suites for TLS handshakes between Gorouter and front-end clients such as load balancers or HAProxy. The default value for this field is `ECDHE-RSA-AES128-GCM-SHA256:TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384`. If you want to modify the default configuration, use an ordered, colon-delimited list of Golang-supported TLS cipher suites in the OpenSSL format. Operators should verify that the ciphers are supported by any clients or front-end components that will initiate TLS handshakes with Gorouter. For a list of TLS ciphers supported by Gorouter, see [Securing Traffic into Cloud Foundry](#).

TLS Cipher Suites for Router *

ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384

Verify that every client participating in TLS handshakes with Gorouter has at least one cipher suite in common with Gorouter.

Note: Specify cipher suites that are supported by the versions configured in the **Minimum version of TLS supported by HAProxy and Router** field.

11. In the **TLS Cipher Suites for HAProxy** field, review the TLS cipher suites for TLS handshakes between HAProxy and its clients such as load balancers and Gorouter. The default value for this field is the following:

DHE-RSA-AES128-GCM-SHA256:DHE-RSA-AES256-GCM-SHA384:ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384 If you want to modify the default configuration, use an ordered, colon-delimited list of TLS cipher suites in the OpenSSL format.

Operators should verify that the ciphers are supported by any clients or front-end components that will initiate TLS handshakes with HAProxy.

TLS Cipher Suites for HAProxy *

DHE-RSA-AES128-GCM-SHA256:DHE-RSA-AES256-GCM-SHA384:ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384

Verify that every client participating in TLS handshakes with HAProxy has at least one cipher suite in common with HAProxy.

Note: Specify cipher suites that are supported by the versions configured in the **Minimum version of TLS supported by HAProxy and Router** field.

12. Under **HAProxy forwards requests to Router over TLS**, select **Enable** or **Disable** based on your deployment layout.

HAProxy forwards requests to Router over TLS. When enabled, HAProxy will forward all requests to the Router over TLS. HAProxy will use the CA provided to verify the certificates provided by the Router. *

☒ Enable

Certificate Authority for HAProxy Backend *

You need to provide a certificate authority for the certificate and key provided in the "Certificate and Private Key for HAProxy and Router" field. HAProxy will verify those certificates using this CA when establishing a connection. If you generated that certificate and key using the "Generate RSA Certificate" feature, then your CA is the Ops Manager CA, and can be found by visiting the "/api/v0/certificate_authorities" API endpoint.

☐ Disable

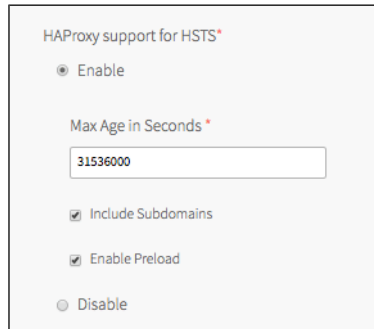

◦ Enable HAProxy forwarding of requests to Router over TLS

| If you want to: | Encrypt communication between HAProxy and the Gorouter |
|-------------------------------|---|
| Then configure the following: | <ol style="list-style-type: none"> 1. Leave Enable selected. 2. In the Certificate Authority for HAProxy Backend field, specify the Certificate Authority (CA) that signed the certificate you configured in the Certificate and Private Key for HAProxy and Router field. <div>  Note: If you used the Generate RSA Certificate link to generate a self-signed certificate, then the CA to specify is the Ops Manager CA, which you can locate at the <code>/api/v0/certificate_authorities</code> endpoint in the Ops Manager API. </div> <ol style="list-style-type: none"> 3. Make sure that Gorouter and HAProxy have TLS cipher suites in common in the TLS Cipher Suites for Router and TLS Cipher Suites for HAProxy fields. |
| See also: | <ul style="list-style-type: none"> ◦ Terminating SSL/TLS at the Load Balancer and Gorouter ◦ Providing a Certificate for Your SSL/TLS Termination Point ◦ Using the Ops Manager API |

◦ Disable HAProxy forwarding of requests to Router over TLS

| If you want to: | Use non-encrypted communication between HAProxy and Gorouter, or you are not using HAProxy |
|-------------------------------|---|
| Then configure the following: | <ol style="list-style-type: none"> 1. Select Disable. 2. If you are not using HAProxy, set the number of HAProxy job instances to <code>0</code> on the Resource Config page. See Disable Unused Resources. |
| See also: | <ul style="list-style-type: none"> ◦ Terminating SSL/TLS at the Gorouter Only ◦ Terminating SSL/TLS at the Load Balancer Only |

13. If you want to force browsers to use HTTPS when making requests to HAProxy, select **Enable** in the **HAProxy support for HSTS** field and complete

the following optional configuration steps:

- a. (Optional) **Enter a Max Age in Seconds** for the HSTS request. By default, the age is set to one year. HAProxy will force HTTPS requests from browsers for the duration of this setting.
- b. (Optional) Select the **Include Subdomains** checkbox to force browsers to use HTTPS requests for all component subdomains.
- c. (Optional) Select the **Enable Preload** checkbox to force instances of Google Chrome, Firefox, and Safari that access your HAProxy to refer to their built-in lists of known hosts that require HTTPS, of which HAProxy is one. This ensures that the first contact a browser has with your HAProxy is an HTTPS request, even if the browser has not yet received an HSTS header from HAProxy.

14. If you are not using SSL encryption or if you are using self-signed certificates, select **Disable SSL certificate verification for this environment**. Selecting this checkbox also disables SSL verification for route services.

 **Note:** For production deployments, Pivotal does not recommend disabling SSL certificate verification.

15. (Optional) If you want HAProxy or the Gorouter to reject any HTTP (non-encrypted) traffic, select the **Disable HTTP on HAProxy and Gorouter** checkbox. When selected, HAProxy and Gorouter will not listen on port 80.

☐ Disable HTTP on HAProxy and Gorouter

16. (Optional) Select the **Disable insecure cookies on the Router** checkbox to set the secure flag for cookies generated by the router.
17. (Optional) To disable the addition of Zipkin tracing headers on the Gorouter, deselect the **Enable Zipkin tracing headers on the router** checkbox. Zipkin tracing headers are enabled by default. For more information about using Zipkin trace logging headers, see [Zipkin Tracing in HTTP Headers](#).
18. (Optional) To stop the Router from writing access logs to local disk, deselect the **Enable Router to write access logs locally** checkbox. You should consider disabling this checkbox for high traffic deployments since logs may not be rotated fast enough and can fill up the disk.
19. By default, the PAS routers handle traffic for applications deployed to an isolation segment created by the PCF Isolation Segment tile. To configure the PAS routers to reject requests for applications within isolation segments, select the **Routers reject requests for Isolation Segments** checkbox.

☐ Routers reject requests for Isolation Segments

Do not enable this option without deploying

routers for each isolation segment. See the following topics for more information:

- [Installing PCF Isolation Segment](#)
- [Sharding Routers for Isolation Segments](#).

20. In the **Choose whether to enable route services** section, choose either **Enable route services** or **Disable route services**. Route services are a class of [marketplace services](#) that perform filtering or content transformation on application requests and responses. See the [Route Services](#) topic for details.
 - a. If you enabled route services, you can also configure the **Bypass security checks for route service lookup** field. Pivotal recommends that you do not enable this field because it has potential security concerns. However, you may need to enable it if your load balancer requires mutual TLS from clients. For more information, see [Configuring Route Service Lookup](#).
21. (Optional) If you want to limit the number of app connections to the backend, enter a value in the **Max Connections Per Backend** field. You can use this field to prevent a poorly behaving app from all the connections and impacting other apps.

To choose a value for this field, review the peak concurrent connections received by instances of the most popular apps in your deployment. You can determine the number of concurrent connections for an app from the `httpStartStop` event metrics emitted for each app request.

If your deployment uses PCF Metrics, you can also obtain this peak concurrent connection information from [Network Metrics](#). The default value is

Max Connections Per Backend *

0

500.

22. Under **Enable Keepalive Connections for Router**, select **Enable** or **Disable**. Keepalive connections are enabled by default. For more information, see [Keepalive Connections](#) in *HTTP Routing*.

Enable Keepalive Connections for Router*

☒ Enable
 ☐ Disable

23. (Optional) To accommodate larger uploads over connections with high latency, increase the number of seconds in the **Router Timeout to Backends** field.
24. (Optional) Use the **Frontend Idle Timeout for Gorouter and HAProxy** field to help prevent connections from your load balancer to Gorouter or HAProxy from being closed prematurely. The value you enter sets the duration, in seconds, that Gorouter or HAProxy maintains an idle open connection from a load balancer that supports keep-alive.

In general, set the value higher than your load balancer's backend idle timeout to avoid the race condition where the load balancer sends a request before it discovers that Gorouter or HAProxy has closed the connection.

See the following table for specific guidance and exceptions to this rule:

| IaaS | Guidance |
|-------|---|
| AWS | AWS ELB has a default timeout of 60 seconds, so Pivotal recommends a value greater than <code>60</code> . |
| Azure | By default, Azure load balancer times out at 240 seconds without sending a TCP RST to clients, so as an exception, Pivotal recommends a value lower than <code>240</code> to force the load balancer to send the TCP RST. |
| GCP | GCP has a default timeout of 600 seconds. For GCP HTTP load balancers, Pivotal recommends a value greater than <code>600</code> . For GCP TCP load balancers, Pivotal recommends a value less than <code>600</code> to force the load balancer to send a TCP RST. |
| Other | Set the timeout value to be greater than that of the load balancer's backend idle timeout. |

 **Note:** Do not set a frontend idle timeout lower than six seconds.

25. (Optional) Increase the value of **Load Balancer Unhealthy Threshold** to specify the amount of time, in seconds, that the router continues to accept connections before shutting down. During this period, healthchecks may report the router as unhealthy, which causes load balancers to failover to other routers. Set this value to an amount greater than or equal to the maximum time it takes your load balancer to consider a router instance unhealthy, given contiguous failed healthchecks.
26. (Optional) Modify the value of **Load Balancer Healthy Threshold**. This field specifies the amount of time, in seconds, to wait until declaring the Router instance started. This allows an external load balancer time to register the Router instance as healthy.

Load Balancer Unhealthy Threshold *

20

Load Balancer Healthy Threshold *

20

27. (Optional) If app developers in your organization want certain HTTP headers to appear in their app logs with information from the Gorouter, specify them in the **HTTP Headers to Log** field. For example, to support app developers that deploy Spring apps to PCF, you can enter [Spring-specific HTTP headers](#).

HTTP Headers to Log

28. If you expect requests larger than the default maximum of 16 Kbytes, enter a new value (in bytes) for **HAProxy Request Max Buffer Size**. You may need to do this, for example, to support apps that embed a large cookie or query string values in headers.
29. If your PCF deployment uses HAProxy and you want it to receive traffic only from specific sources, use the following fields:
- **HAProxy Protected Domains:** Enter a comma-separated list of domains to protect from unknown source requests.
 - **HAProxy Trusted CIDRs:** Optionally, enter a space-separated list of CIDRs to limit which IP addresses from the **Protected Domains** can send traffic to PCF.

HAProxy Protected Domains

A comma-separated list of domains to protect from requests from unknown sources. Use this property in conjunction with "Trusted CIDRs" to protect these domains from requests from unknown sources.

HAProxy Trusted CIDRs

30. The **Loggregator Port** defaults to `443` if left blank. Enter a new value to override the default.

Container Network Interface Plugin*

☒ Silk

31. For **Container Network Interface Plugin**, ensure **Silk** is selected and review the following fields:

 **Note:** The **External** option exists to support NSX-T integration for vSphere deployments.

- (Optional) You can change the value in the **Applications Network Maximum Transmission Unit (MTU)** field. Pivotal recommends setting the MTU value for your application network to `1454`. Some configurations, such as networks that use GRE tunnels, may require a smaller MTU value.
- (Optional) Enter an IP range for the overlay network in the **Overlay Subnet** box. If you do not set a custom range, Ops Manager uses `10.255.0.0/16`.

 **warning:** The overlay network IP range must not conflict with any other IP addresses in your network.

- Enter a UDP port number in the **VXLAN Tunnel Endpoint Port** box. If you do not set a custom port, Ops Manager uses 4789.
- For **Denied logging interval**, set the per-second rate limit for packets blocked by either a container-specific [networking policy](#) or by [Application Security Group](#) rules applied across the space, org, or deployment. This field defaults to `1`.
- For **UDP logging interval**, set the per-second rate limit for UDP packets sent and received. This field defaults to `100`.
- To enable logging for app traffic, select **Log traffic for all accepted/denied application packets**. See [Manage Logging for Container-to-Container Networking](#) for more information.
- For **DNS Servers**, enter `8.8.8.8` only if you have BOSH disabled. Otherwise, you cannot use this field to override the DNS servers used in containers.

 **Note:** If you do not want to configure your DNS servers with `8.8.8.8`, contact [Pivotal Support](#).

32. For **DNS Search Domains**, enter DNS search domains for your containers as a comma-separated list. DNS on your containers appends these names to its host names, to resolve them into full domain names.

DNS Search Domains

example.com, myapps.com

DNS search domains to be used in containers. A comma-separated list can be specified.

33. For **Database Connection Timeout**, set the connection timeout for clients of the policy server and silk databases. The default value is `120`. You may need to increase this value if your deployment experiences timeout issues related to Container-to-Container Networking.
34. (Optional) TCP Routing is disabled by default. You should enable this feature if your DNS sends TCP traffic through a load balancer rather than directly to a TCP router. To enable TCP routing:
- Select **Enable TCP Routing**.
 - For **TCP Routing Ports**, enter a single port or a range of ports for the load balancer to forward to. These are the same ports that you configured in the [Pre-Deployment Steps](#) of the *Enabling TCP Routing* topic.
 - To support multiple TCP routes, Pivotal recommends allocating multiple ports.

- To allocate a list of ports rather than a range:

1. Enter a single port in the **TCP Routing Ports** field.
2. After deploying PAS, follow the directions in [Configuring a List of TCP Routing Ports](#) to add TCP routing ports using the cf CLI.

Enable TCP requests to your apps via specific ports on the TCP router. You will want to configure a load balancer to forward these TCP requests to the TCP routers. If you do not have a load balancer, then you can also send traffic directly to the TCP router.*

☐ Select this option if you prefer to enable TCP Routing at a later time
☒ Enable TCP Routing

TCP Routing Ports (one-time configuration, if you want to update this value you can via the CF CLI) *

1024-1123

- c. For GCP, you also need to specify the name of a GCP TCP load balancer in the **LOAD BALANCER** column of TCP Router job of the **Resource Config** screen. You configure this later on in PAS. See the [Configure Load Balancers](#) section of this topic.

35. (Optional) To disable TCP routing, click **Select this option if you prefer to enable TCP Routing at a later time** For more information, see the [Configuring TCP Routing in PAS](#) [↗](#) topic.

36. Click **Save**.

Step 7: Configure Application Containers

1. Select **Application Containers**.

Enable microservice frameworks, private Docker registries, and other services that support your applications at a container level.

☒ Enable Custom Buildpacks
☒ Allow SSH access to app containers
☒ Enable SSH when an app is created
☒ Enable the GrootFS container image plugin for Garden RunC
☐ Router uses TLS to verify application identity

Private Docker Insecure Registry Whitelist

10.10.10.10:8888,example.com:8888

Docker Images Disk-Cleanup Scheduling on Cell VMs*

☐ Never clean up Cell disk-space
☐ Routinely clean up Cell disk-space
☒ Clean up disk-space once threshold is reached

Threshold of Disk-Used (MB) (min: 1) *

10240

2. The **Enable Custom Buildpacks** checkbox governs the ability to pass a custom buildpack URL to the `-b` option of the `cf push` command. By default, this ability is enabled, letting developers use custom buildpacks when deploying apps. Disable this option by disabling the checkbox. For more

information about custom buildpacks, refer to the [buildpacks](#) section of the PCF documentation.

3. The **Allow SSH access to app containers** checkbox controls SSH access to application instances. Enable the checkbox to permit SSH access across your deployment, and disable it to prevent all SSH access. See the [Application SSH Overview](#) topic for information about SSH access permissions at the space and app scope.
4. If you want to enable SSH access for new apps by default in spaces that allow SSH, select **Enable SSH when an app is created**. If you deselect the checkbox, developers can still enable SSH after pushing their apps by running `cf enable-ssh APP-NAME`.
5. If you want to disable the Garden Root filesystem (GrootFS), deselect the **Enable the GrootFS container image plugin for Garden RunC** checkbox. Pivotal recommends using this plugin, so it is enabled by default. However, some external components are sensitive to dependencies with filesystems such as GrootFS. If you experience issues, such as antivirus or firewall compatibility problems, deselect the checkbox to roll back to the plugin that is built into Garden RunC. For more information about GrootFS, see [Component: Garden](#) and [Container Mechanics](#).

 **Note:** If you modify this setting, Pivotal recommends recreating all VMs in the BOSH Director config. You can do this by selecting the **Recreate all VMs** checkbox in the **Director Config** pane of the BOSH Director tile before you redeploy.

6. To enable Gorouter to verify app identity using TLS, select the **Router uses TLS to verify application identity** checkbox.

Verifying app identity using TLS enables encryption between router and app containers and guards against misrouting during control plane failures. For more information about Gorouter route consistency modes, see [Preventing Misrouting in HTTP Routing](#).

 **warning:** TLS routing requires an additional 32 MB of RAM capacity on Diego cells per app instance. It also requires additional CPU capacity on Diego cells. If the total amount of Diego cell memory available is less than 32 MB times the number of running app instances, scale your Diego cells before configuring the Gorouter with TLS.

 **Warning:** You may see an increase of memory and CPU usage for your Gorouters after enabling TLS routing. If the total amount of memory and CPU usage of the Gorouters in your environment are close to the size limit, scale your Gorouters before enabling TLS routing.

7. You can configure Pivotal Application Service (PAS) to run app instances in Docker containers by supplying their IP address ranges in the **Private Docker Insecure Registry Whitelist** textbox. See the [Using Docker Registries](#) topic for more information.
8. Select your preference for **Docker Images Disk-Cleanup Scheduling on Cell VMs**. If you choose **Clean up disk-space once threshold is reached**, enter a **Threshold of Disk-Used** in megabytes. For more information about the configuration options and how to configure a threshold, see [Configuring Docker Images Disk-Cleanup Scheduling](#).
9. Enter a number in the **Max Inflight Container Starts** textbox. This number configures the maximum number of started instances across the Diego cells in your deployment. For more information about this feature, see [Setting a Maximum Number of Started Containers](#).
10. Under **Enabling NFSv3 volume services**, select **Enable** or **Disable**. NFS volume services allow application developers to bind existing NFS volumes to their applications for shared file access. For more information, see the [Enabling NFS Volume Services](#) topic.

 **Note:** In a clean install, NFSv3 volume services is enabled by default. In an upgrade, NFSv3 volume services is set to the same setting as it was in the previous deployment.

11. (Optional) To configure LDAP for NFSv3 volume services, do the following:

Enabling NFSv3 volume services will allow application developers to bind existing NFS volumes to their applications for shared file access. *

☒ Enable

LDAP Service Account User

LDAP Service Account Password

LDAP Server Host

LDAP Server Port

LDAP User Fully-Qualified Domain Name

☐ Disable

Format of timestamps in Diego logs*

☒ RFC3339 timestamps (e.g. 2018-02-09T00:54:13.479724884Z)

☐ Seconds since the Unix epoch (e.g. 1518137653.479724884)

Save

- For **LDAP Service Account User**, enter the username of the service account in LDAP that will manage volume services.
- For **LDAP Service Account Password**, enter the password for the service account.
- For **LDAP Server Host**, enter the hostname or IP address of the LDAP server.
- For **LDAP Server Port**, enter the LDAP server port number. If you do not specify a port number, Ops Manager uses 389.
- For **LDAP User Fully-Qualified Domain Name**, enter the fully qualified path to the LDAP service account. For example, if you have a service account named `volume-services` that belongs to organizational units (OU) named `service-accounts` and `my-company`, and your domain is named `domain`, the fully qualified path looks like the following:

```
CN=volume-services,OU=service-accounts,OU=my-company,DC=domain,DC=com
```

- By default, PAS manages container images using the [GrootFS](#) plugin for Garden-runC. If you experience issues with GrootFS, you can disable the plugin and use the image plugin built into Garden-runC.
- Select the **Format of timestamps in Diego logs**, either **RFC3339 timestamps** or **Seconds since the Unix epoch**. Fresh PAS v2.2 installations default to **RFC3339 timestamps**, while upgrades to PAS v2.2 from previous versions default to **Seconds since the Unix epoch**.
- You can optionally modify the **Default health check timeout**. The value configured for this field is the amount of time allowed to elapse between starting up an app and the first healthy response from the app. If the health check does not receive a healthy response within the configured timeout, then the app is declared unhealthy. The default timeout is `60` seconds and the maximum configurable timeout is `600` seconds.
- Click **Save**.

Step 8: Configure Application Developer Controls

- Select **Application Developer Controls**.

Configure restrictions and default settings for applications pushed to Application Service.

Maximum File Upload Size (MB) (min: 1024, max: 2048) *

Default App Memory (MB) (min: 64, max: 2048) *

Default App Memory Quota per Org (MB) (min: 10240, max: 102400) *

Maximum Disk Quota per App (MB) (min: 512, max: 20480) *

Default Disk Quota per App (MB) (min: 512, max: 20480) *

Default Service Instances Quota per Org (min: 0, max: 1000) *

Staging Timeout (Seconds) *

☐ Allow Space Developers to manage network policies

☒ Enable Service Discovery for Apps

Save

2. Enter the **Maximum File Upload Size (MB)**. This is the maximum size of an application upload.
3. Enter the **Default App Memory (MB)**. This is the amount of RAM allocated by default to a newly pushed application if no value is specified with the cf CLI.
4. Enter the **Default App Memory Quota per Org**. This is the default memory limit for all applications in an org. The specified limit only applies to the first installation of PAS. After the initial installation, operators can use the cf CLI to change the default value.
5. Enter the **Maximum Disk Quota per App (MB)**. This is the maximum amount of disk allowed per application.

Note: If you allow developers to push large applications, PAS may have trouble placing them on Cells. Additionally, in the event of a system upgrade or an outage that causes a rolling deploy, larger applications may not successfully re-deploy if there is insufficient disk capacity. Monitor your deployment to ensure your Cells have sufficient disk to run your applications.

6. Enter the **Default Disk Quota per App (MB)**. This is the amount of disk allocated by default to a newly pushed application if no value is specified with the cf CLI.
7. Enter the **Default Service Instances Quota per Org**. The specified limit only applies to the first installation of PAS. After the initial installation, operators can use the cf CLI to change the default value .
8. Enter the **Staging Timeout (Seconds)**. When you stage an application droplet with the Cloud Controller, the server times out after the number of

seconds you specify in this field.

9. Select the **Allow Space Developers to manage network policies** checkbox to permit developers to manage their own network policies for their applications.
10. The **Enable Service Discovery for Apps** checkbox, which enables service discovery between applications, is enabled by default. To disable this feature, clear this checkbox. For more information about application service discovery, see the [App Service Discovery](#) section of the *Understanding Container-to-Container Networking* topic.
11. Click **Save**.

Step 9: Review Application Security Groups

Setting appropriate [Application Security Groups](#) is critical for a secure deployment. Type in the box to acknowledge that once the Pivotal Application Service (PAS) deployment completes, you will review and set the appropriate application security groups. See [Restricting App Access to Internal PCF Components](#) for instructions.

Setting appropriate Application Security Groups that control application network policy is the responsibility of the Elastic Runtime administration team. Please refer to the Application Security Groups topic in the Pivotal Cloud Foundry documentation for more detail on completing this activity after the Elastic Runtime deployment completes.

Type X to acknowledge that you understand this message *

Save

Step 10: Configure UAA

1. Select **UAA**.
2. (Optional) Under **JWT Issuer URI**, enter the URI that UAA uses as the issuer when generating tokens.

JWT Issuer URI

3. Under **SAML Service Provider Credentials**, enter a certificate and private key to be used by UAA as a SAML Service Provider for signing outgoing SAML authentication requests. You can provide an existing certificate and private key from your trusted Certificate Authority or generate a self-signed certificate. The following domain must be associated with the certificate: `*.login.YOUR-SYSTEM-DOMAIN`.

Note: The Pivotal Single Sign-On Service and Pivotal Spring Cloud Services tiles require the `*.login.YOUR-SYSTEM-DOMAIN`.

4. If the private key specified under **Service Provider Credentials** is password-protected, enter the password under **SAML Service Provider Key**

SAML Service Provider Credentials *

-----BEGIN CERTIFICATE-----

Save

Interface (cf CLI) login access and refresh. Most deployments use the defaults.

- (Optional) In the **Global Login Session Max Timeout** and **Global Login Session Idle Timeout** fields, change the maximum number of seconds before a global login times out. These fields apply to the following:
 - Default zone sessions:** Sessions in Apps Manager, PCF Metrics, and other web UIs that use the UAA default zones
 - Identity zone sessions:** Sessions in apps that use a UAA identity zone, such as a Single Sign-On service plan

8. (Optional) Customize the text prompts used for username and password from the cf CLI and Apps Manager login popup by entering values for **Customize Username Label (on login page)** and **Customize Password Label (on login page)**.
9. (Optional) The **Proxy IPs Regular Expression** field contains a pipe-delimited set of regular expressions that UAA considers to be reverse proxy IP addresses. UAA respects the `x-forwarded-for` and `x-forwarded-proto` headers coming from IP addresses that match these regular expressions. To configure UAA to respond properly to Gorouter or HAProxy requests coming from a public IP address, append a regular expression or regular expressions to match the public IP address.
10. You can configure UAA to use an internal MySQL database provided with PCF, or you can configure an external database provider. Follow the procedures in either the [Internal Database Configuration](#) or the [External Database Configuration](#) section below.

 **Note:** For GCP installations, Pivotal recommends selecting **External** and using Google Cloud SQL.

 **Note:** If you are performing an upgrade, do not modify your existing internal database configuration or you may lose data. You must migrate your existing data before changing the configuration. See [Upgrading Pivotal Cloud Foundry](#) for additional upgrade information, and contact [Pivotal Support](#)  for help.

Internal Database Configuration

If you chose to not deploy a Google Cloud SQL database with Terraform, follow these steps.

When you configure the UAA to use an internal MySQL database, it uses the type of database selected in the **Databases** pane, which can be one of two options. See [Migrate to Internal Percona MySQL](#) for details.

1. Select **Internal MySQL**.

Choose the location of your UAA database *

☒ Internal MySQL (preferred for complete high-availability)

☐ External (preferred if, for example, you use AWS RDS)

2. Click **Save**.
3. Ensure that you complete the [Configure Internal MySQL](#) step later in this topic to configure high availability for your internal MySQL databases.

External Database Configuration

If you chose to deploy a Google Cloud SQL database with Terraform, follow these steps.

1. From the **UAA** section in Pivotal Application Service (PAS), select **External**.

Choose the location of your UAA database *

☐ Internal MySQL (preferred for complete high-availability)

☒ External (preferred if, for example, you use AWS RDS)

Hostname *

TCP Port *

Username *

Password *

2. Complete the fields as follows:

- **Hostname:** Enter the value of `sql_db_ip` from your Terraform output.
- **TCP Port:** Enter `3306`.
- **User Account and Authentication database username:** Enter the value of `pas_sql_username` from your Terraform output.
- **User Account and Authentication database password:** Enter the value of `pas_sql_password` from your Terraform output.

3. Click **Save**.

Step 11: Configure CredHub

 **Note:** Enabling CredHub is not required. However, you cannot leave the fields under **Encryption Keys** blank. If you do not intend to use CredHub, enter any text in the **Name** and **Key** fields as placeholder values.

1. Select **CredHub**.
2. Select **Internal** for your CredHub database. For GCP environments, Runtime CredHub has the following limitations:
 - If you choose **External**, Runtime CredHub does not work. See [CredHub Database Cannot be External on GCP](#).
 - Runtime CredHub only works if both the [system databases](#) and the CredHub database are set to **Internal**.
3. Under **Encryption Keys**, specify one or more keys to use for encrypting and decrypting the values stored in the CredHub database.

Encryption Keys

Name *

Name of the encryption key.

Provider*

Internal

Key *

Secret

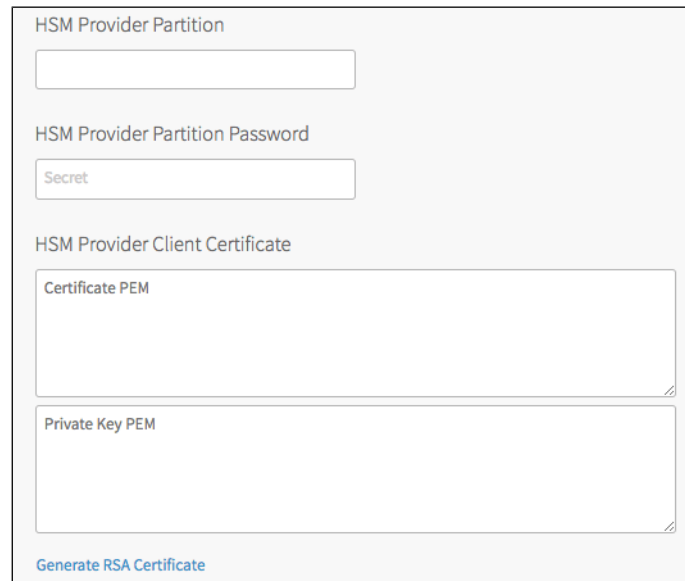

☐ Primary

- **Name.** This is the name of the encryption key.
 - If you plan to use internal encryption, enter any key name.
 - If you plan to use an HSM as your encryption provider, enter a key name that already exists on your HSM or a new key name. For each new key name, CredHub generates a key in **HSM Provider Partition** that you configure below.
- **Provider.** This is the provider of the encryption key. If you plan to configure an HSM provider and HSM servers below, select **HSM**. Otherwise, select **Internal**.
- **Key.** If you select internal encryption, this key is used for encrypting all data. The key must be at least 20 characters long.
 - If you selected **Internal** above, enter a randomly generated value under **Key**.
 - If you selected **HSM** above, enter a placeholder value under **Key**. CredHub does not use this key for encryption. However, you cannot leave the **Key** field blank.
- **Primary.** This checkbox is used for marking the key you specified above as the primary encryption key. You must mark one key as **Primary**. Do not mark more than one key as **Primary**.

 **Note:** For information about using additional keys for key rotation, see the [Rotating Runtime CredHub Encryption Keys](#) topic.

4. (Optional) To configure CredHub to use an HSM, complete the following fields:

- **HSM Provider Partition.** This is the name of the HSM provider partition.
- **HSM Provider Partition Password.** This password is used to access the HSM provider partition.
- **HSM Provider Client Certificate.** This is the client certificate for the HSM. For more information, see [Create and Register HSM Clients](#)  in the

Preparing CredHub HSMs for Configuration topic.

- In the **HSM Provider Servers** section, click **Add** to add an HSM server. You can add multiple HSM servers. For each HSM server, complete the following fields:
 - **Host Address.** This is the host name or IP address of the HSM server.
 - **Port.** This is the port of the HSM server. If you do not know your port address, enter `1792`.
 - **Partition Serial Number.** This is the serial number of the HSM partition.
 - **HSM Certificate.** This is the certificate for the HSM server. The HSM presents this certificate to CredHub to establish a two-way TLS connection.

5. If your deployment uses any PCF services that support storing service instance credentials in CredHub and you want to enable this feature, select the **Secure Service Instance Credentials** checkbox.
6. Click **Save**.
7. Select the **Resource Config** pane.
8. Under the **Job** column of the **CredHub** row, set the number of instances to `2`. This is the minimum instance count required for high availability.
9. Click **Save**.

For more information about using CredHub for securing service instance credentials, see [Securing Service Instance Credentials with Runtime CredHub](#).

Step 12: Configure Authentication and Enterprise SSO

1. Select **Authentication and Enterprise SSO**.

Configure your user store access, which can be an internal user store (managed by Cloud Foundry's UAA) or an external user store (LDAP or SAML). You can also adjust the lifetimes of authentication tokens.

Configure your UAA user account store with either internal or external authentication mechanisms *

☒ Internal UAA (provided by Elastic Runtime; configure your password policy below)

Minimum Password Length *

Minimum Uppercase Characters Required for Password *

Minimum Lowercase Characters Required for Password *

Minimum Numerical Digits Required for Password *

Minimum Special Characters Required for Password *

Maximum Password Entry Attempts Allowed *

2. To authenticate user sign-ons, your deployment can use one of three types of user database: the UAA server's internal user store, an external SAML identity provider, or an external LDAP server.

- To use the internal UAA, select the **Internal** option and follow the instructions in the [Configuring UAA Password Policy](#) topic to configure your password policy.
- To connect to an external identity provider through SAML, scroll down to select the **SAML Identity Provider** option and follow the instructions in the [Configuring PCF for SAML](#) section of the *Configuring Authentication and Enterprise SSO for Pivotal Application Service (PAS)* topic.
- To connect to an external LDAP server, scroll down to select the **LDAP Server** option and follow the instructions in the [Configuring LDAP](#) section of the *Configuring Authentication and Enterprise SSO for PAS* topic.

3. Click **Save**.

Step 13: Configure System Databases

You can configure PAS to use Google Cloud SQL for the databases required by PAS.

 **Note:** If you are performing an upgrade, do not modify your existing internal database configuration or you may lose data. You must migrate your existing data first before changing the configuration. Contact Pivotal Support for help. See [Upgrading Pivotal Cloud Foundry](#) for additional upgrade information.

Internal Database Configuration

 **Note:** For GCP installations, Pivotal recommends selecting **External** and using Google Cloud SQL. Only use internal MySQL for non-production or test installations on GCP.

 **Note:** For Runtime CredHub to work, you must use internal MySQL. See [CredHub Database Cannot be External on GCP](#).

 **Note:** Follow these steps if you did not modify your Terraform variables file to deploy an Google CloudSQL instance.

If you want to use internal databases for your deployment, perform the following steps:

1. Select **Databases**.
2. Select one of the **Internal Databases** options:
 - **Internal Databases - MySQL - Percona XtraDB Cluster** uses [Percona Server](#) with TLS encryption between server cluster nodes.
 - **Internal Databases - MySQL - MariaDB Galera Cluster** uses [MariaDB](#) with cluster nodes communicating over plaintext.

 **warning:** Changing existing internal databases from **MySQL - MariaDB Galera Cluster** to **MySQL - Percona XtraDB Cluster** migrates the databases after you click **Apply Changes**, causing temporary system downtime. See [Migrate to Internal Percona MySQL](#) for details.

Choose the location of your system databases. Please consult the documentation for migrating existing installations from MariaDB to Percona. *

- ☒ Internal Databases - MySQL - Percona XtraDB Cluster
- ☐ Internal Databases - MySQL - MariaDB Galera Cluster (deprecated - planned to be removed in PAS 2.4)
- ☐ External Databases - (e.g. AWS RDS)

Save

3. Click **Save**.

Then proceed to [Step 14: \(Optional\) Configure Internal MySQL](#) to configure high availability for your internal MySQL databases.

External Database Configuration

 **Note:** If you use external MySQL, you cannot use Runtime CredHub. See [CredHub Database Cannot be External on GCP](#).

 **Note:** Follow these steps if you modified your Terraform variables file to deploy an Google CloudSQL instance.

Pivotal recommends using an external database such as Google Cloud SQL for high availability reasons.

On GCP, you can use Google Cloud SQL and use the automated backup and high availability replica features.

 **Note:** To configure an external database for UAA, see the *External Database Configuration* section of [Configure UAA](#).

 **warning:** Protect whichever database you use in your deployment with a password.

To specify your PAS databases, perform the following steps:

1. Select the **External Databases** option.
2. Complete the following fields:
 - **Hostname:** Enter the value of `sql_db_ip` from your Terraform output.
 - **TCP Port:** Enter `3306`.
 - For the username and password field for each relational database, enter the values of `pas_sql_username` and `pas_sql_password` from your

Place the databases used by Elastic Runtime components.

Choose the location of your system databases *

☐ Internal Databases - MySQL (preferred for complete high-availability)

☒ External Databases (preferred if, for example, you use AWS RDS)

Hostname *

35[REDACTED]

TCP Port *

3306

App Usage Service Database Username *

v[REDACTED]

App Usage Service Database Password *

[Change](#)

Autoscaling Service Database Username *

VA[REDACTED]

Autoscaling Service Database Password *

[Change](#)

Cloud Controller Database Username *

IA[REDACTED]

Cloud Controller Database Password *

[Change](#)

Terraform output.

3. Click **Save**.

Step 14: (Optional) Configure Internal MySQL

 **Note:** You only need to configure this section if you have selected one of the **Internal Databases - MySQL** options in the **Databases** section.

To use internal MySQL in High Availability configuration, you define a load balancer rule that lets PAS components send queries a single hostname backed by two redundant proxies. Each proxy then directs query traffic to three MySQL server nodes.

1. Allocate an internal load balancer rule to balance traffic between two static IP addresses. The static IP addresses cannot be within the range that you have reserved for PAS.

The load balancer rule is separate from the software provided by Pivotal, and you need to define it within your infrastructure.

- **Make your idle time out long enough to not interrupt long-running queries.** When queries take a long time, the load balancer can time out and interrupt the query.
For example, [AWS's Elastic Load Balancer](#) has a default idle timeout of 60 seconds, so queries that take longer than this duration sever the MySQL connection and return an error.
- **Configure a healthcheck or monitor, using TCP against port 1936.** This defaults to TCP port `1936`, to maintain backwards compatibility with previous releases. This port is not configurable. Unauthenticated healthchecks against port 3306 may cause the service to become unavailable and require manual intervention to fix.
- **Configure the load balancer to route traffic for TCP port 3306 to the IPs of all proxy instances on TCP port 3306.**

- Record the hostname of the load balancer rule and the two static IP addresses.

 **warning:** You must configure a load balancer to achieve complete high availability.

- From the PAS tile in Ops Manager, Select **Internal MySQL**.
- In the **MySQL Proxy IPs** field, enter the static IP addresses used by the internal MySQL load balancer rule.

Only configure this section if you selected Internal Databases - MySQL in the previous Databases section.

A proxy tier routes MySQL connections from internal components to healthy cluster nodes. Configure DNS and/or your own load balancer to point to multiple proxy instances for increased availability. TCP healthchecks can be configured against port 1936.

The automated backups functionality works with any S3-compatible file store that can receive your backup files.

MySQL Proxy IPs

MySQL Service Hostname

- For **MySQL Service Hostname**, enter the IP address or hostname for your load balancer. If you leave this field blank, components are configured with the IP address of the first proxy instance entered above.
- In the **Replication canary time period** field, leave the default of 30 seconds or modify the value based on the needs of your deployment. Lower numbers cause the canary to run more frequently, which means that the canary reacts more quickly to replication failure but adds load to the database.
- In the **Replication canary read delay** field, leave the default of 20 seconds or modify the value based on the needs of your deployment. This field configures how long the canary waits, in seconds, before verifying that data is replicating across each MySQL node. Clusters under heavy load can experience a small replication lag as write-sets are committed across the nodes.
- (**Required**): In the **E-mail address** field, enter the email address where the MySQL service sends alerts when the cluster experiences a replication issue or when a node is not allowed to auto-rejoin the cluster.
- To prohibit the creation of command line history files on the MySQL nodes, disable the **Allow Command History** checkbox.
- To allow the admin and roadmin to connect from any remote host, enable the **Allow Remote Admin Access** checkbox. When the checkbox is disabled, admins must `bosh ssh` into each MySQL VM to connect as the MySQL super user.

 **Note:** Network configuration and Application Security Groups restrictions may still limit a client's ability to establish a connection with the databases.

- For **Cluster Probe Timeout**, enter the maximum amount of time, in seconds, that a new node will search for existing cluster nodes. If left blank, the default value is 10 seconds.

Replication canary time period *

Replication canary read delay *

E-mail address (required) *

☒ Allow Command History

Cluster Probe Timeout

11. For **Max Connections**, enter the maximum number of connections allowed to the database. If left blank, the default value is 1500.
12. If you want to log audit events for internal MySQL, select **Enable server activity logging** under **Server Activity Logging**.
 - a. For the **Event types** field, you can enter the events you want the MySQL service to log. By default, this field includes `connect` and `query`, which tracks who connects to the system and what queries are processed.

Server Activity Logging *

☐ Disable server activity logging

☒ Enable server activity logging

Event types *

Load Balancer Healthy Threshold *

Load Balancer Unhealthy Threshold *

Save

13. Enter values for the following fields:
 - **Load Balancer Healthy Threshold:** Specifies the amount of time, in seconds, to wait until declaring the MySQL Proxy instance started. This allows an external load balancer time to register the instance as healthy.
 - **Load Balancer Unhealthy Threshold:** Specifies the amount of time, in seconds, that the MySQL Proxy continues to accept connections before shutting down. During this period, the Healthcheck reports as unhealthy to cause load balancers to fail over to other proxies. You must enter a value greater than or equal to the maximum time it takes your load balancer to consider a proxy instance unhealthy, given repeated failed healthchecks.
14. If you want to enable the MySQL interruptor feature, select the checkbox to **Prevent node auto re-join**. This feature stops all writes to the MySQL database if it notices an inconsistency in the dataset between the nodes. For more information, see the [Interruptor](#) section in the MySQL for PCF documentation.
15. Click **Save**.

For more information on how to monitor the node health of your MySQL Proxy instances, see [Using the MySQL Proxy](#).

Step 15: Configure File Storage

When configuring file storage for the Cloud Controller in PAS, you can select one of the following:

- Internal WebDAV filestore
- External S3-compatible or Ceph-compatible filestore
- External Google Cloud Storage with Access Key and Secret Key
- External Google Cloud Storage with Service Account
- External Azure Cloud Storage

 **Note:** Use one of the Google Cloud Storage options if you added `create_gcs_buckets = true` to your `terraform.tfvars` file.

For production-level PCF deployments on GCP, Pivotal recommends selecting **External Google Cloud Storage** to minimize downtime. For more information about production-level PCF deployments on GCP, see the [Reference Architecture for Pivotal Cloud Foundry on GCP](#).

For additional factors to consider when selecting file storage, see the [Considerations for Selecting File Storage in Pivotal Cloud Foundry](#) topic.

Internal Filestore

Internal file storage is only appropriate for small, non-production deployments.

To use the PCF internal filestore, perform the following steps:

1. In the Pivotal Application Service (PAS) tile, select **File Storage**.
2. Select **Internal WebDAV**, and click **Save**.

External Google Cloud Storage

PAS can use Google Cloud Storage (GCS) as its external filestore by using either a GCP interoperable storage access key or your GCS Service Account. See below for how to configure each option.

External Google Cloud Storage with Access Key and Secret Key

1. Select the **External Google Cloud Storage with Access Key and Secret Key** option

This section determines where you would like to place your Application Service Cloud Controller's file storage.

Configure your Cloud Controller's filesystem*

- ☐ Internal WebDAV (provided by Application Service)
- ☐ External S3-Compatible File Store (if you want to use a service like S3 or Ceph)
- ☒ External Google Cloud Storage with Access Key and Secret Key

Access Key *

Secret Key *

Buildpacks Bucket Name *

Bucket for storing app buildpacks.

Droplets Bucket Name *

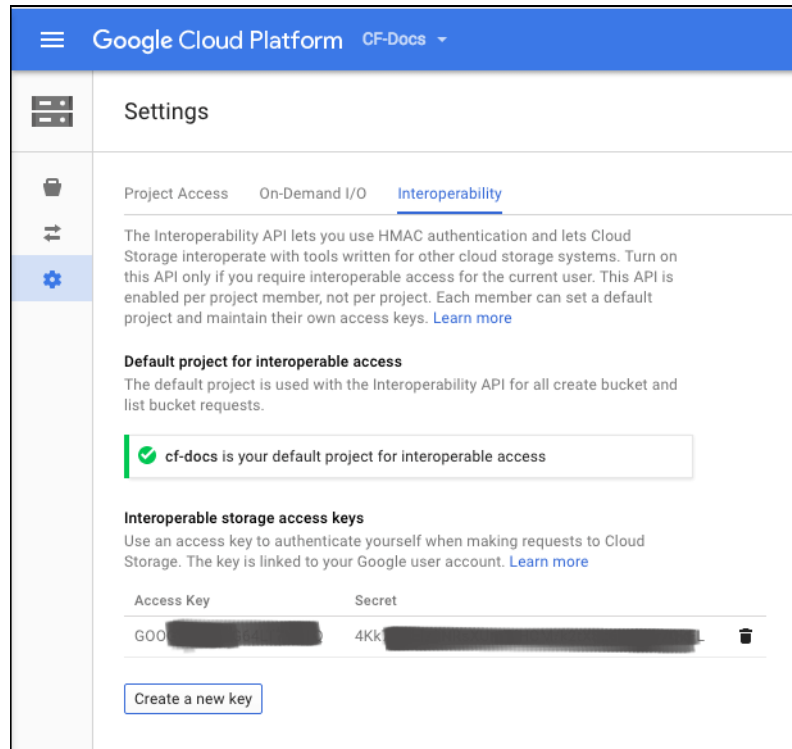

Packages Bucket Name *

Resources Bucket Name *

- ☐ External Google Cloud Storage with Service Account
- ☐ External Azure Storage

2. Enter values for **Access Key** and **Secret Key**. To obtain the values for these fields:

- a. In the GCP Console, navigate to the **Storage** tab, then click **Settings**.
- b. Click **Interoperability**.
- c. If necessary, click **Enable interoperability access**. If interoperability access is already enabled, confirm that the default project matches the project where you are installing PCF.

- d. Click **Create a new key**.
- e. Copy and paste the generated values into the corresponding PAS fields. PCF uses these values for authentication when connecting to Google Cloud Storage.
- f. Enter the names of the storage buckets you created in [Deploying Ops Manager on GCP Using Terraform](#):
 - **Buildpacks Bucket Name:** Enter the value of `buildpacks_bucket` from your Terraform output.
 - **Droplets Bucket Name:** Enter the value of `droplets_bucket` from your Terraform output.
 - **Resources Bucket Name:** Enter the value of `packages_bucket` from your Terraform output.
 - **Packages Bucket Name:** Enter the value of `resources_bucket` from your Terraform output.
- g. Click **Save**.

External Google Cloud Storage with Service Account

1. Select the **External Google Cloud Storage with Service Account** option

Configure your Cloud Controller's filesystem*

☐ Internal WebDAV (provided by Application Service)
☐ External S3-Compatible File Store (if you want to use a service like S3 or Ceph)
☐ External Google Cloud Storage with Access Key and Secret Key
☒ External Google Cloud Storage with Service Account

GCP Project ID *

GCP Service Account Email *

 Your Google Cloud Platform Service Account Email.

GCP Service Account Key JSON *

Buildpacks Bucket Name *

- For **GCP Project ID** enter the Project ID on your GCP Console that you want to use for your PAS file storage.
- For **GCP Service Account Email** enter the email address associated with your GCP account.
- For **GCP Service Account JSON** enter the account key that you use to access the specified GCP project, in JSON format.
- Enter the names of the storage buckets you created in [Deploying Ops Manager on GCP Using Terraform](#):
 - **Buildpacks Bucket Name**: Enter the value of `buildpacks_bucket` from your Terraform output.
 - **Droplets Bucket Name**: Enter the value of `droplets_bucket` from your Terraform output.
 - **Resources Bucket Name**: Enter the value of `packages_bucket` from your Terraform output.
 - **Packages Bucket Name**: Enter the value of `resources_bucket` from your Terraform output.
- Click **Save**.

Other IaaS Storage Options

[Azure Storage](#) and [External S3-Compatible File Storage](#) are also available as file storage options, but Pivotal does not recommend these for a typical PCF on GCP installation.

Step 16: (Optional) Configure System Logging

You can configure system logging in PAS to forward log messages from PAS component VMs to an external service. Pivotal recommends forwarding logs to an external service for use in troubleshooting.

Note: The following instructions explain how to configure system logging for PAS component VMs. To forward logs from PCF tiles to an external service, you must also configure system logging in each tile. See the documentation for the given tiles for information about configuring system logging.

To configure system logging in PAS, do the following:

- In the PAS **Settings** tab, select the **System Logging** pane. The following image shows the **System Logging** pane.

Optionally configure rsyslog to forward platform component logs to an external service. If you do not fill these fields, platform logs will not be forwarded but will remain available on the component VMs and for download via Ops Manager.

Address

Port

Transport Protocol

Encrypt syslog using TLS?*

- ☒ No
☐ Yes

Syslog Drain Buffer Size (# of messages) *

☒ Include container metrics in SysLog Drains

☒ Enable Cloud Controller security event logging

☐ Use TCP for file forwarding local transport

☒ Don't Forward Debug Logs

Custom rsyslog Configuration

Save

2. For **Address**, enter the IP address of the syslog server.
3. For **Port**, enter the port of the syslog server. The default port for a syslog server is `514`.

Note: The host must be reachable from the PAS network and accept UDP or TCP connections. Ensure the syslog server listens on external interfaces.

4. For **Transport Protocol**, select a transport protocol for log forwarding.
5. For **Encrypt syslog using TLS?**, select **Yes** to use TLS encryption when forwarding logs to a remote server.
 - a. For **Permitted Peer**, enter either the name or SHA1 fingerprint of the remote peer.
 - b. For **TLS CA Certificate**, enter the TLS CA certificate for the remote server.
6. For **Syslog Drain Buffer Size**, enter the number of messages from the Loggregator Agent that the Doppler server can store before it begins to drop messages. See the [Loggregator Guide for Cloud Foundry Operators](#) topic for more details.
7. Disable the **Include container metrics in Syslog Drains** checkbox to prevent the [CF Drain CLI plugin](#) from including app container metrics in syslog drains. This feature is enabled by default.

8. Enable the **Enable Cloud Controller security event logging** checkbox to include security events in the log stream. This feature logs all API requests, including the endpoint, user, source IP address, and request result, in the Common Event Format (CEF).
9. Enable the **Use TCP for file forwarding local transport** checkbox to transmit logs over TCP. This prevents log truncation, but may cause performance issues.
10. Disable the **Don't Forward Debug Logs** checkbox to forward DEBUG syslog messages to an external service. This checkbox is enabled by default.

Note: Some PAS components generate a high volume of DEBUG syslog messages. Enabling the **Don't Forward Debug Logs** checkbox prevents PAS components from forwarding the DEBUG syslog messages to external services. However, PAS still writes the messages to the local disk.

11. For **Custom rsyslog Configuration**, enter a custom syslog rule. For more information about adding custom syslog rules, see [Customizing Syslog Rules](#).
12. Click **Save**.

To configure Ops Manager for system logging, see the [Settings](#) section in the *Using the Ops Manager Interface* topic.

Step 17: (Optional) Customize Apps Manager

This section describes how to configure **Custom Branding** and **Apps Manager** to customize the appearance and functionality of Apps Manager. For more information about the **Custom Branding** configuration settings, see [Custom Branding Apps Manager](#).

1. Select **Custom Branding**. Use this section to configure the text, colors, and images of the interface that developers see when they log in, create an account, reset their password, or use Apps Manager.

Customize colors, images, and text for Apps Manager and the Cloud Foundry login portal.

Company Name

Accent Color

Main Logo (PNGs only)

Square Logo/Favicon (PNGs only)

Add

2. Click **Save** to save your settings in this section.
3. Select **Apps Manager**.

Configure Apps Manager

☒ Enable Invitations

☐ Display Marketplace Service Plan Prices

Supported currencies as JSON *

```
{ "usd": "$", "eur": "€" }
```

Product Name

Marketplace Name

Customize Sidebar Links Add

You may configure up to 10 links in the Apps Manager sidebar.

- ▶ Marketplace 🗑️
- ▶ Docs 🗑️
- ▶ Tools 🗑️

Apps Manager Memory Usage (MB) (min: 128)

Invitations Memory Usage (MB) (min: 256)

Apps Manager Polling Interval *

30

Apps manager polling interval in seconds. As a workaround to reduce load on the Cloud Controller API, increase the polling interval or set to 0 to stop polling. Values between 0 and 30 will default to 30 seconds.

Save

4. Select **Enable Invitations** to enable invitations in Apps Manager. Space Managers can invite new users for a given space, Org Managers can invite new users for a given org, and Admins can invite new users across all orgs and spaces. See the [Inviting New Users](#) section of the *Managing User Roles with Apps Manager* topic for more information.
5. Select **Display Marketplace Service Plan Prices** to display the prices for your services plans in the Marketplace.
6. Enter the **Supported currencies as JSON** to appear in the Marketplace. Use the format `{ "CURRENCY-CODE": "SYMBOL" }`. This defaults to `{ "usd": "$", "eur": "€" }`.
7. Use **Product Name**, **Marketplace Name**, and **Customize Sidebar Links** to configure page names and sidebar links in the **Apps Manager** and **Marketplace** pages.
8. The **Apps Manager Memory Usage (MB)** field sets the memory limit with which to deploy the Apps Manager app. Use this field to increase the memory limit if the app fails to start with an `out of memory` error.
9. The **Invitations Memory Usage (MB)** field sets the memory limit with which to deploy the Invitations app. Use this field to increase the memory limit if the app fails to start with an `out of memory` error.

10. The **Apps Manager Polling Interval** field provides a temporary fix if Apps Manager usage degrades Cloud Controller response times. In this case, you can use this field to reduce the load on the Cloud Controller and ensure Apps Manager remains available while you troubleshoot the Cloud Controller. Pivotal recommends that you do not keep this field modified as a long term fix because it can degrade Apps Manager performance. You can optionally do the following:

- Increase the polling interval above the default of `30` seconds.

 **Note:** If you enter a value between `0` and `30`, the field is automatically set to `30`.

- Disable polling by entering `0`. This stops Apps Manager from refreshing data automatically, but users can update displayed data by reloading Apps Manager manually.

11. Click **Save** to save your settings in this section.

Step 18: (Optional) Configure Email Notifications

PAS uses SMTP to send invitations and confirmations to Apps Manager users. You must complete the **Email Notifications** page if you want to enable end-user self-registration.

1. Select **Email Notifications**.

Configure Simple Mail Transfer Protocol for the Notifications application to send email notifications about your deployment. This application is deployed as an errand in Elastic Runtime. If you do not need this service, leave this section blank and disable the Notifications and Notifications UI errands.

From Email

Address of SMTP Server

Port of SMTP Server

SMTP Server Credentials

[Change](#)

☒ SMTP Enable Automatic STARTTLS

SMTP Authentication Mechanism*

SMTP CRAMMD5 secret

2. Enter your reply-to and SMTP email information.

 **Note:** For GCP, you must use port `2525`. Ports `25` and `587` are not allowed on GCP Compute Engine.

3. Verify your authentication requirements with your email administrator and use the **SMTP Authentication Mechanism** dropdown to select `None`, `Plain`, or `CRAMMD5`. If you have no SMTP authentication requirements, select `None`.

- If you selected `CRAMMD5` as your authentication mechanism, enter a secret in the **SMTP CRAMMD5 secret** field.
- Click **Save**.

Note: If you do not configure the SMTP settings using this form, the administrator must create orgs and users using the cf CLI. See [Creating and Managing Users with the cf CLI](#) for more information.

Step 19: (Optional) Configure App Autoscaler

To use App Autoscaler, you must create an instance of the service and bind it to an app. To create an instance of App Autoscaler and bind it to an app, see [Set Up App Autoscaler](#) in the *Scaling an Application Using App Autoscaler* topic.

- Click **App Autoscaler**.

Configure the App Autoscaler

Autoscaler Instance Count (min: 1) *

Autoscaler API Instance Count (min: 1) *

Metric Collection Interval (min: 60, max: 3600) (min: 60, max: 3600) *

Scaling Interval (min: 15, max: 120) (min: 15, max: 120) *

☐ Verbose Logging

☐ Disable API Connection Pooling

☒ Enable Notifications

- Review the following settings:

- Autoscaler Instance Count:** How many instances of the App Autoscaler service you want to deploy. The default value is `3`. For high availability, set this number to `3` or higher. You should set the instance count to an odd number to avoid split-brain scenarios during leadership elections. Larger environments may require more instances than the default number.
- Autoscaler API Instance Count:** How many instances of the App Autoscaler API you want to deploy. The default value is `1`. Larger environments may require more instances than the default number.
- Metric Collection Interval:** How many seconds of data collection you want App Autoscaler to evaluate when making scaling decisions. The minimum interval is 60 seconds, and the maximum interval is 3600 seconds. The default value is `120`. Increase this number if the metrics you use in your scaling rules are emitted less frequently than the existing Metric Collection Interval.
- Scaling Interval:** How frequently App Autoscaler evaluates an app for scaling. The minimum interval is 15 seconds, and the maximum interval is 120 seconds. The default value is `35`.
- Verbose Logging** (checkbox): Enables verbose logging for App Autoscaler. Verbose logging is disabled by default. Select this checkbox to see more detailed logs. Verbose logs show specific reasons why App Autoscaler scaled the app, including information about minimum and maximum instance limits, App Autoscaler's status. For more information about App Autoscaler logs, see [App Autoscaler Events and Notifications](#).
- Disable API Connection Pooling:** API connection pooling increases performance by reducing the cost associated with establishing new connections. If you do not want to keep connections open for reuse, select this option.

3. Click **Save**.

Step 20: Configure Cloud Controller

1. Click **Cloud Controller**.

Configure the Cloud Controller

Cloud Controller DB Encryption Key

Secret

Enabling CF API Rate Limiting will prevent API consumers from overwhelming the platform API servers. Limits are imposed on a per-user or per-client basis and reset on an hourly interval. *

☐ Enable
 ☒ Disable

Save

2. Enter your **Cloud Controller DB Encryption Key** if all of the following are true:

- You deployed Pivotal Application Service (PAS) previously.
- You then stopped PAS or it crashed.
- You are re-deploying PAS with a backup of your Cloud Controller database.

See [Backing Up Pivotal Cloud Foundry](#) for more information.

3. CF API Rate Limiting prevents API consumers from overwhelming the platform API servers. Limits are imposed on a per-user or per-client basis and reset on an hourly interval.

To disable CF API Rate Limiting, select **Disable** under **Enable CF API Rate Limiting**. To enable CF API Rate Limiting, perform the following steps:

- Under **Enable CF API Rate Limiting**, select **Enable**.
- For **General Limit**, enter the number of requests a user or client is allowed to make over an hour interval for all endpoints that do not have a custom limit. The default value is `2000`.
- For **Unauthenticated Limit**, enter the number of requests an unauthenticated client is allowed to make over an hour interval. The default value is `100`.

4. Click **Save**.

Step 21: Configure Smoke Tests

The Smoke Tests errand runs basic functionality tests against your Pivotal Application Service (PAS) deployment after an installation or update. In this section, choose where to run smoke tests. In the **Errands** section, you can choose whether or not to run the Smoke Tests errand.

1. Select **Smoke Tests**.
2. If you have a shared apps domain, select **Temporary space within the system organization**, which creates a temporary space within the `system` organization for running smoke tests and deletes the space afterwards. Otherwise, select **Specified org and space** and complete the fields to specify where you want to run smoke tests.

Specify a Cloud Foundry organization and space where smoke tests can run if in the future you delete your Elastic Runtime deployment domains.

Choose where to deploy applications when running the smoke tests *

- ☐ Temporary space within the system organization (This is deleted after smoke tests finish.)
- ☒ Specified org and space (The org and space must have a domain available for routing.)

Organization *

Space *

Domain *

Save

3. Click **Save**.

Step 22: (Optional) Enable Advanced Features

The **Advanced Features** section of Pivotal Application Service (PAS) includes new functionality that may have certain constraints. Although these features are fully supported, Pivotal recommends caution when using them in production environments.

Diego Cell Memory and Disk Overcommit

If your apps do not use the full allocation of disk space and memory set in the **Resource Config** tab, you might want use this feature. These fields control the amount to overcommit disk and memory resources to each Diego Cell VM.

For example, you might want to use the overcommit if your apps use a small amount of disk and memory capacity compared to the amounts set in the **Resource Config** settings for **Diego Cell**.

Note: Due to the risk of app failure and the deployment-specific nature of disk and memory use, Pivotal has no recommendation about how much, if any, memory or disk space to overcommit.

To enable overcommit, do the following:

1. Select **Advanced Features**.

Cell Memory Capacity (MB) (min: 1)

Cell Disk Capacity (MB) (min: 1)

2. Enter the total desired amount of Diego cell memory value in the **Cell Memory Capacity (MB)** field. Refer to the **Diego Cell** row in the **Resource Config** tab for the current Cell memory capacity settings that this field overrides.
3. Enter the total desired amount of Diego cell disk capacity value in the **Cell Disk Capacity (MB)** field. Refer to the **Diego Cell** row in the **Resource Config** tab for the current Cell disk capacity settings that this field overrides.
4. Click **Save**.

 **Note:** Entries made to each of these two fields set the total amount of resources allocated, not the overage.

Whitelist for Non-RFC-1918 Private Networks

Some private networks require extra configuration so that internal file storage (WebDAV) can communicate with other PCF processes.

The **Whitelist for non-RFC-1918 Private Networks** field is provided for deployments that use a non-RFC 1918 private network. This is typically a private network other than `10.0.0.0/8`, `172.16.0.0/12`, or `192.168.0.0/16`.

Most PCF deployments do not require any modifications to this field.

To add your private network to the whitelist, do the following:

1. Select **Advanced Features**.
2. Append a new `allow` rule to the existing contents of the **Whitelist for non-RFC-1918 Private Networks** field.

Whitelist for non-RFC-1918 Private Networks *

allow 10.0.0.0/8;;allow 172.16.0.0/12;;allow .

If your Elastic Runtime deployment is using a private network that is not RFC 1918 (10.0.0.0/8, 172.16.0.0/12, 192.168.0.0/16), then you must type in "allow <your-network>;" here. It is important to include the word "allow" and the semi-colon at the end. For example, "allow 172.99.0.0/24;"

Include the word `allow`, the network CIDR range to allow, and a semi-colon (`;`) at the end. For example: `allow 172.99.0.0/24;`

3. Click **Save**.

CF CLI Connection Timeout

The **CF CLI Connection Timeout** field allows you to override the default five second timeout of the Cloud Foundry Command Line Interface (cf CLI) used within your PCF deployment. This timeout affects the cf CLI command used to push PAS errand apps such as Notifications, Autoscaler, and Apps Manager.

Set the value of this field to a higher value, in seconds, if you are experiencing domain name resolution timeouts when pushing errands in PAS.

To modify the value of the **CF CLI Connection Timeout**, perform the following steps:

1. Select **Advanced Features**.

CF CLI Connection Timeout

15

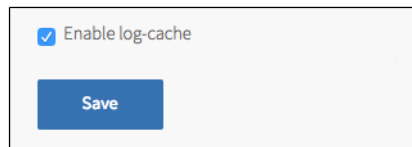

2. Add a value, in seconds, to the **CF CLI Connection Timeout** field.
3. Click **Save**.

Log Cache

Log Cache is an in-memory caching layer for logs and metrics. This Loggregator feature lets users filter and query logs through a CLI or API endpoints. Cached logs are available on demand. For more information about Log Cache, see [Enable Log Cache](#) in the *Configuring Logging in PASTopic*.

To configure the **Enable log-cache** checkbox, do the following:

1. Select **Advanced Features**.

2. Select or deselect the **Enable log-cache** checkbox.
3. Click **Save**.

Database Connection Limits

You can configure the maximum number of concurrent database connections that diego and container networking components can have. Use the field beginning with **Maximum number of open connections...** for a given component. The placeholder values for each field are the default values.

When there are not enough connections available, such as during a time of heavy load, components may experience degraded performance and sometimes failure. To resolve or prevent this, you can increase and fine-tune database connection limits for the component.

⚠ warning: Decreasing the value of this field for a component may affect the amount of time it takes for it to respond to requests.

Step 23: Configure Errands

Errands are scripts that Ops Manager runs automatically when it installs or uninstalls a product, such as a new version of Pivotal Application Service (PAS). There are two types of errands: *post-deploy errands* run after the product is installed, and *pre-delete errands* run before the product is uninstalled.

By default, Ops Manager always runs all errands.

The PAS tile **Errands** pane lets you change these run rules. For each errand, you can select **On** to run it always or **Off** to never run it.

For more information about how Ops Manager manages errands, see the [Managing Errands in Ops Manager](#) topic.

💡 Note: Several errands, such as App Autoscaler and Notifications, deploy apps that provide services for your deployment. When one of these apps is running, selecting **Off** for the corresponding errand on a subsequent installation does not stop the app.

- **Smoke Test Errand** verifies that your deployment can do the following:
 - Push, scale, and delete apps
 - Create and delete orgs and spaces
- **Usage Service Errand** deploys the Pivotal Usage Service application, which Apps Manager depends on.
- **Apps Manager Errand** deploys Apps Manager, a dashboard for managing apps, services, orgs, users, and spaces. Until you deploy Apps Manager, you must perform these functions through the cf CLI. After Apps Manager has been deployed, Pivotal recommends setting this errand to **Off** for subsequent PAS deployments. For more information about Apps Manager, see the [Getting Started with the Apps Manager](#) topic.
- **Notifications Errand** deploys an API for sending email notifications to your PCF platform users.

💡 Note: The Notifications app requires that you [configure SMTP](#) with a username and password, even if you set the value of **SMTP Authentication Mechanism** to `none`.

- **Notifications UI Errand** deploys a dashboard for users to manage notification subscriptions.
- **App Autoscaler Errand** enables you to configure your apps to automatically scale in response to changes in their usage load. See the [Scaling an Application Using Autoscaler](#) topic for more information.
- **NFS Broker Errand** enables you to use NFS Volume Services by installing the NFS Broker app in PAS. See the [Enabling NFS Volume Services](#) topic for more information.

Step 24: Configure Load Balancers

1. Click **Resource Config**.

- Under the **LOAD BALANCERS** column of the **Router** row, enter a comma-delimited list consisting of the values of `ws_router_pool` and `http_lb_backend_name` from your Terraform output. For example, `tcp:pcf-cf-ws,http:pcf-httpslb`. These are the names of the TCP WebSockets and HTTP(S) load balancers for your deployment.

 **Note:** Do not add a space between key/value pairs in the `LOAD BALANCER` field or it will fail.

 **Note:** If you are using HAProxy in your deployment, then enter the above load balancer values in the `LOAD BALANCERS` field of the **HAProxy** row instead of the **Router** row. For a high availability configuration, scale up the HAProxy job to more than one instance.

- If you have enabled TCP routing in the **Networking** pane, add the value of `tcp_router_pool` from your Terraform output, prepended with `tcp:`, to the **LOAD BALANCERS** column of the **TCP Router** row. For example, `tcp:pcf-cf-tcp`.
- Enter the name of your SSH load balancer depending on which release you are using.
 - PAS:** Under the **LOAD BALANCERS** column of the **Diego Brain** row, enter the value of `ssh_router_pool` from your Terraform output, prepended with `tcp:`. For example, `tcp:MY-PCF-ssh-proxy`.
 - Small Footprint Runtime:** Under the **LOAD BALANCERS** column of the **Control** row, enter the value of `ssh_router_pool` from your Terraform output, prepended with `tcp:`.
- Verify that the **Internet Connected** checkbox for every job is checked. The terraform templates do not provision a Network Address Translation (NAT) box for Internet connectivity to your VMs so instead they will be provided with ephemeral public IP addresses to allow the jobs to reach the Internet.

 **Note:** If you want to provision a Network Address Translation (NAT) box to provide Internet connectivity to your VMs instead of providing them with public IP addresses, deselect the **Internet Connected** checkboxes. For more information about using NAT in GCP, see the [GCP documentation](#).

- Click **Save**.

Step 25: (Optional) Scale Down and Disable Resources

 **Note:** The **Resource Config** pane has fewer VMs if you are installing the [Small Footprint Runtime](#).

 **Note:** The Small Footprint Runtime does not default to a highly available configuration. It defaults to the minimum configuration. If you want to make the Small Footprint Runtime highly available, scale the **Compute**, **Router**, and **Database** VMs to `3` instances and scale the **Control** VM to `2` instances.

Pivotal Application Service (PAS) defaults to a highly available resource configuration. However, you may need to perform additional procedures to make your deployment highly available. See the [Zero Downtime Deployment and Scaling in CF](#) and the [Scaling Instances in PAS](#) topics for more information.

If you do not want a highly available resource configuration, you must scale down your instances manually by navigating to the **Resource Config** section and using the dropdowns under **Instances** for each job.

By default, PAS also uses an internal filestore and internal databases. If you configure PAS to use external resources, you can disable the corresponding system-provided resources in Ops Manager to reduce costs and administrative overhead.

To disable specific VMs in Ops Manager, do the following:

- Click **Resource Config**.
- If you configured PAS to use an external S3-compatible filestore, enter `0` in **Instances** in the **File Storage** field.
- If you selected **External** when configuring the UAA, System, and CredHub databases, edit the following fields:
 - MySQL Proxy:** Enter `0` in **Instances**.
 - MySQL Server:** Enter `0` in **Instances**.
 - MySQL Monitor:** Enter `0` in **Instances**.
- If you disabled TCP routing, enter `0` **Instances** in the **TCP Router** field.
- If you are not using HAProxy, enter `0` **Instances** in the **HAProxy** field.

6. Click **Save**.

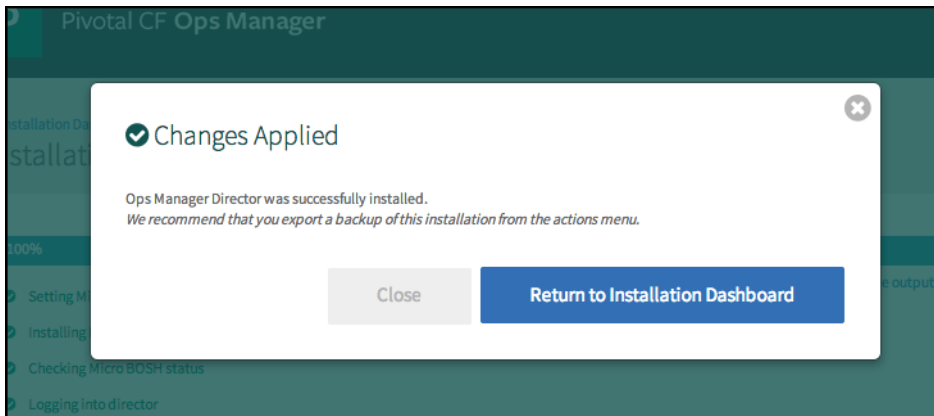

Step 26: Download Stemcell

This step is only required if your Ops Manager does not already have the stemcell version required by PAS. For more information about importing stemcells, see [Importing and Managing Stemcells](#).

1. Open the [Stemcell product page](#) in the Pivotal Network. *Note, you may have to log in.*
2. Download the appropriate stemcell version targeted for your IaaS.
3. Navigate to **Stemcell Library** in the **Installation Dashboard**.
4. Click **Import Stemcell** to import the downloaded stemcell `.tgz` file.
5. When prompted, enable the Ops Manager product checkbox to stage your stemcell.
6. Click **Apply Stemcell to Products**.

Step 27: Complete the PAS Installation

1. Click the **Installation Dashboard** link to return to the Installation Dashboard.
2. Click **Apply Changes**. The install process generally requires a minimum of 90 minutes to complete. The image shows the Changes Applied window that displays when the installation process successfully completes.

Configuring a Shared VPC on GCP

Page last updated:

This guide describes the preparation steps required to configure and integrate a shared Virtual Private Cloud (VPC) on Google Cloud Platform (GCP) with Pivotal Cloud Foundry (PCF).

GCP Shared VPC, formerly known as Google Cross-Project Networking (XPN), enables you to assign GCP resources to individual projects within an organization but allows communication and shared services between projects. For more information about shared VPCs, see [Shared VPC Overview](#) in the GCP documentation.

Prerequisites

To configure a shared VPC, you must assign your project to a Cloud Organization. Confirm that you have a Cloud Organization associated with your GCP account using one of the following methods:

- **GCP Console:** From <https://console.cloud.google.com>, click the **Organization** dropdown at the top of the page to display all organizations you belong to.
- **gcloud Command Line Interface (CLI):** From the command line, run `gcloud organizations list` to display all organizations you belong to. See [gcloud Overview](#) in the Google documentation to install the gcloud CLI.

For more information, see [Creating and Managing Organizations](#) in the GCP documentation. If you do not have a Cloud Organization, contact GCP support.

Step 1: Provision the Shared VPC

Follow the [Enabling a shared VPC host project](#) procedure in the GCP documentation. This procedure requires shared VPC admin permissions.

Step 2: Create a Shared VPC Network

Use the procedures in the [Preparing to Deploy Ops Manager on GCP Manually](#) topic to create a new network with firewall rules. Do the following:

- [Step 3: Create a GCP Network with Subnet](#)
- [Step 5: Create Firewall Rules for the Network](#)

Step 3: Connect the Shared VPC to Ops Manager

You can use the [GCP console](#) or the gcloud CLI to connect the shared VPC host project with Ops Manager.

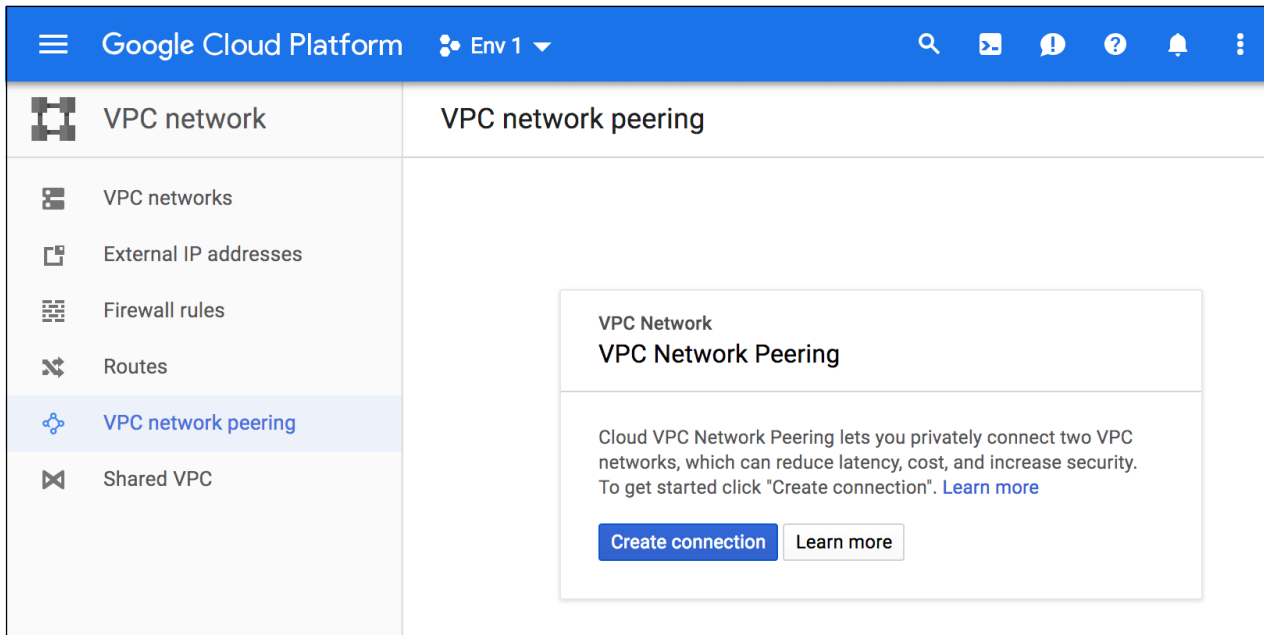

For more information, see [VPC Network Peering](#) in the GCP documentation.

⚠ warning: VPC Network Peering is currently in beta and intended for evaluation and test purposes only.

Set Up VPC Network Peering with GCP Console

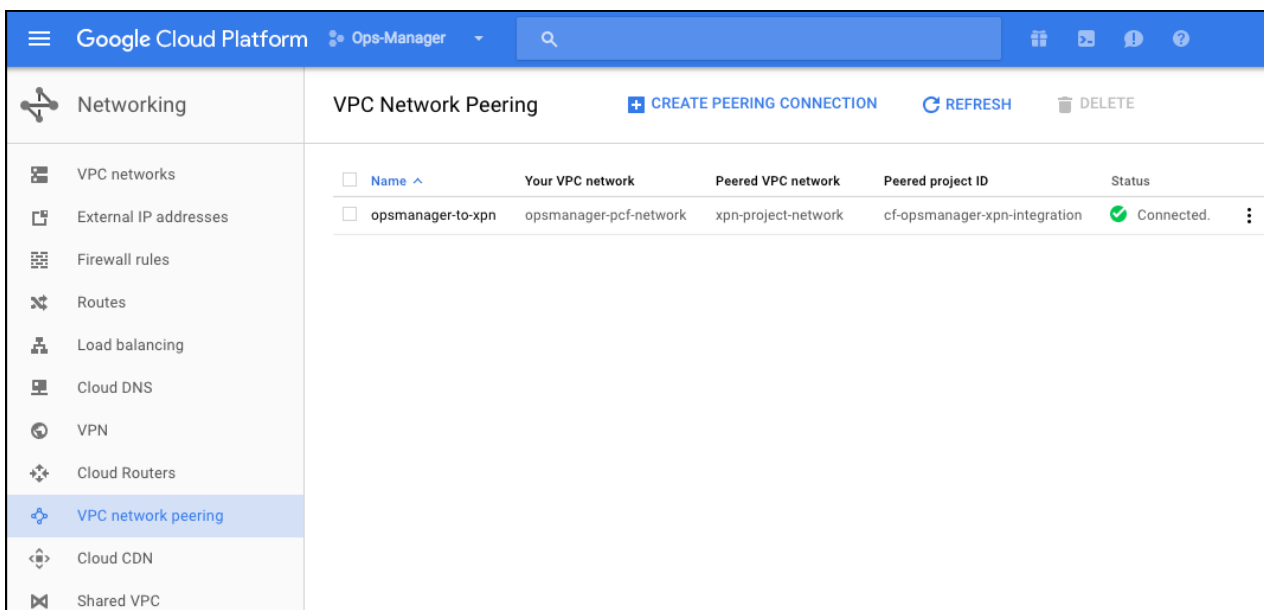

To set up VPC network peering with the GCP console, do the following:

1. From the GCP console, click **Networking**, then **VPC network peering**.

2. Click **Create Connection**.

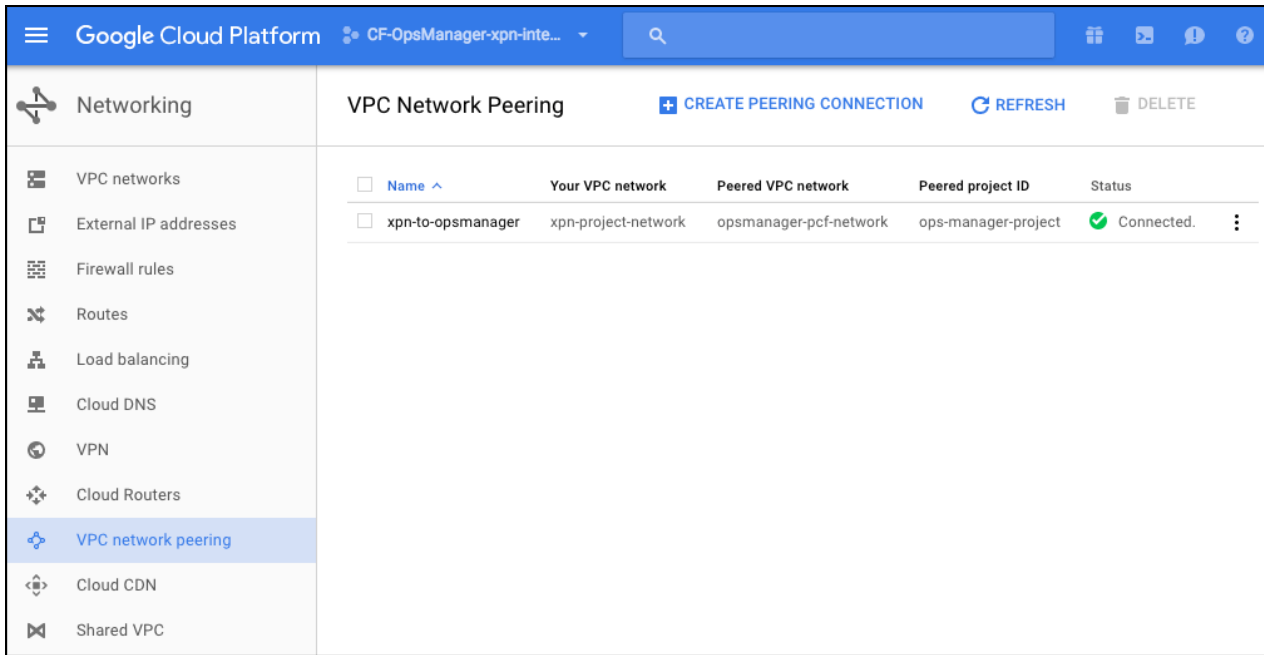

3. Enter a name for the network connection from the Ops Manager project to the new shared network, such as `opsmanager-to-xpn`.

4. Click **Save**.

5. Click **Create Connection**.

6. Enter a name for the network connection from the new shared network to the Ops Manager project, such as `xpn-to-opsmanager`.

7. Click **Save**.

Set Up VPC Network Peering with gcloud CLI

To set up VPC network peering with the gcloud CLI, do the following:

1. Enter the following command, replacing `OPSMANAGER-PROJECT` with the name of the project that contains your Ops Manager installation:

```
$ gcloud config set project OPSMANAGER-PROJECT
```

2. Enter the following command to create a connection from the Ops Manager project to the new shared VPC project:

```
$ gcloud beta compute networks peerings create OPSMANAGER-TO-VPC \
  --network OPSMANAGER-NETWORK \
  --peer-project VPC-HOST-PROJECT \
  --peer-network VPC-NETWORK \
  --auto-create-routes
```

Replace the following text in the command above:

- `OPSMANAGER-TO-VPC` : Choose a name for the connection, such as `om-to-vpc`.
- `OPSMANAGER-NETWORK` : Enter the name of the network assigned to the Ops Manager project in GCP, such as `my-om-project`.
- `VPC-HOST-PROJECT` : Enter the name you gave the shared VPC project in [Step 1: Provision the Shared VPC](#).
- `VPC-NETWORK` : Enter the name of the network you gave the shared VPC project in [Step 2: Create Shared VPC Networks](#).

3. Enter the following command, replacing `VPC-HOST-PROJECT` with the new shared VPC project you created in [Step 1: Provision the Shared VPC](#):

```
$ gcloud config set project VPC-HOST-PROJECT
```

4. Enter the following command to create a connection from the new shared VPC project to the Ops Manager project:

```
$ gcloud beta compute networks peerings create VPC-TO-OPSMANAGER \
  --network VPC-NETWORK \
  --peer-project OPSMANAGER-PROJECT \
  --peer-network OPSMANAGER-NETWORK \
  --auto-create-routes
```

Replace the following text and run the following command:

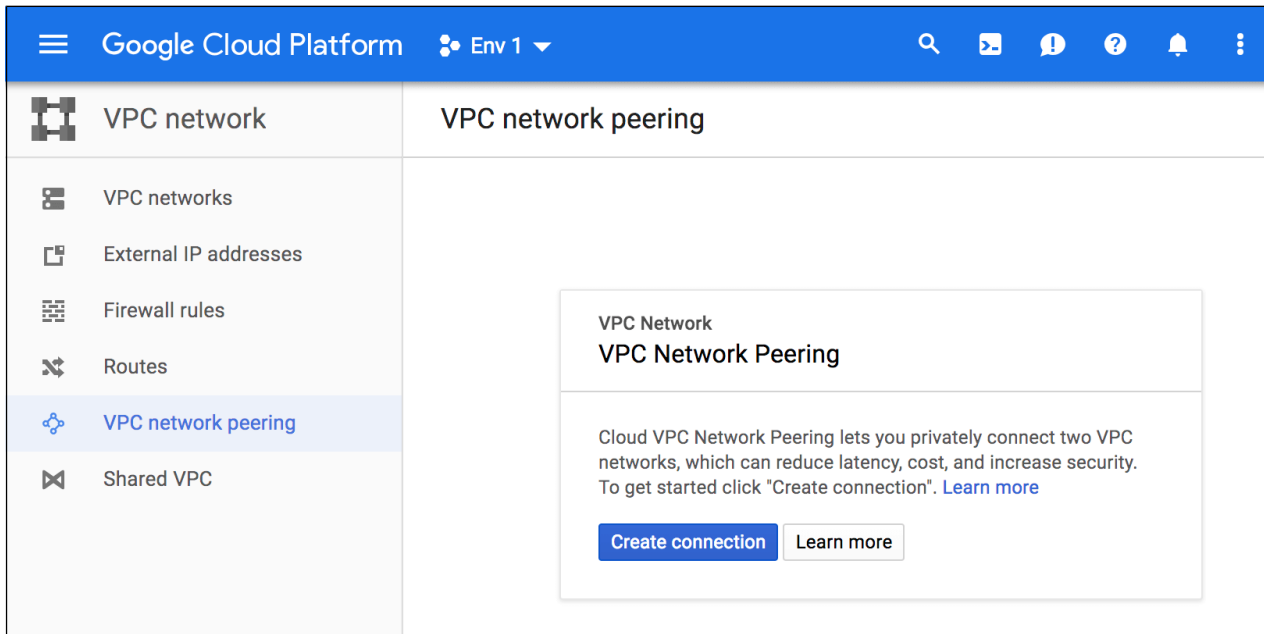

- `VPC-TO-OPSMANAGER` : Choose a name for the connection, such as `vpc-to-om`.
- `VPC-NETWORK` : Enter the name of the network you gave the shared VPC project in [Step 2: Create Shared VPC Networks](#).
- `OPSMANAGER-PROJECT` : Enter the name of the project that contains your Ops Manager installation.

- `OPSMANAGER-NETWORK` : Enter the name of the network assigned to the Ops Manager project in GCP.

Step 4: Verify the Shared VPC Configuration

After configuring a shared VPC, use the following procedure to verify that the shared VPC host project VM appears in the Ops Manager project.

1. From <https://console.cloud.google.com>, select the Ops Manager project from the drop-down menu at the top of the page.
2. Click **Networking**, then **VPC networks**.

3. Confirm that the shared VPC network name appears in the **Subnets** list.
4. Confirm that the shared VPC network **IP address ranges** match what you set for the new VPC project in [Step 2: Create a Shared VPC Network](#).

Deleting PCF from GCP

Page last updated:

When you deploy [Pivotal Cloud Foundry](#) (PCF) to Google Cloud Platform (GCP), you provision a set of resources. This topic describes how to delete the resources associated with a PCF deployment.

You can delete the resources in one of two ways:

- If you created a separate project for your PCF deployment, perform the procedure in the [Delete the Project](#) delete the project.
- If the project that contains your PCF deployment also contains other resources that you want to preserve, perform the procedure in the [Delete PCF Resources](#) section.

Delete the Project

Perform the following steps to delete the project for your PCF deployment:

1. Navigate to the GCP Console Dashboard.
2. Under your **Project**, click **Manage project settings**.
3. Click **DELETE PROJECT**.
4. Enter your project ID and click **SHUT DOWN** to confirm.

Delete PCF Resources

Perform the following steps to delete the resources associated with your PCF deployment:

1. Navigate to the GCP Console Dashboard.
2. Click the upper left icon and select **Networking**.
3. Click **Load balancing**.
4. Perform the following steps for all load balancers associated with your PCF deployment:
 - a. Click the trashcan icon next to the load balancer.
 - b. In the next dialog, select any **health checks** and **backend services** associated with the load balancer.
 - c. Click **DELETE LOAD BALANCER AND THE SELECTED RESOURCES**.
5. Click the upper left icon and select **Compute Engine**.
6. Perform the following steps for **VM instances**, **Instance groups**, and **Disks**:
 - a. Select the checkbox next to the PCF resource.
 - b. When all PCF resources are selected, click **DELETE** in the upper right.
 - c. Click **DELETE** to confirm.
7. Click the upper left icon and select **Networking**.
8. Click **External IP addresses**.
9. Select all external IP addresses associated with your PCF deployment, and click **RELEASE STATIC ADDRESS**.
10. Click on **Networks**, and perform the following steps for any networks you created for PCF:
 - a. Click the name of the network.
 - b. Click **DELETE NETWORK**.
 - c. Click **DELETE** to confirm.
11. Click the upper left icon and select **IAM & Admin**.
12. Click the trashcan icon next to the `bosh` service account you created for PCF and click **REMOVE**.

13. Navigate to **Compute Engine > Metadata > SSH Keys**. Delete the `vcap` SSH key that you created for the project.

Troubleshooting PCF on GCP

Page last updated:

This topic describes how to troubleshoot known issues when deploying Pivotal Cloud Foundry (PCF) on Google Cloud Platform (GCP).

Problems Connecting with Single Sign-On (SSO)

Users may be unable to connect to applications running on PCF using SSO.

Explanation

SSO does not support multi-subnets.

Solution

Ensure that you have configured only one subnet. See [Preparing to Deploy Ops Manager on GCP Manually](#).

Uploading PAS Tile Causes Ops Manager Rails Application Crash

Uploading the Pivotal Application Service (PAS) tile causes the Ops Manager Rails application to crash.

Explanation

In compressed format, the PAS tile is 5 GB in size. However, when uncompressed during installation, the PAS tile requires additional disk space that can exhaust the space allocated to the boot disk.

Solution

Ensure that the boot disk is allocated at least 50 GB of space. See *Step 3: Create the Ops Manager VM Instance* in [Deploying Ops Manager on GCP Manually](#).

PAS Deployment Fails - MySQL Monitor replication-canary Job

During installation of the PAS tile, the replication-canary job fails to start. The error reported in the installation log resembles the following:

```
Started updating job mysql_monitor > mysql_monitor/0
(48e7ec82-3cdf-41af-9d0f-90d1f12683c8) (canary). Failed: 'mysql_monitor/0
(48e7ec82-3cdf-41af-9d0f-90d1f12683c8)' is not running after update.
Review logs for failed jobs: replication-canary (00:05:13)

Error 400007: 'mysql_monitor/0 (48e7ec82-3cdf-41af-9d0f-90d1f12683c8)'
is not running after update.
Review logs for failed jobs: replication-canary
```

Explanation

This error can appear as a result of incorrect configuration of network traffic and missed communication between the Gorouter and a load balancer.

Solution

1. Make sure you have selected the **Forward SSL to PAS Router** option in your [PAS Network Configuration](#).
 2. Verify that you have configured the firewall rules properly and that TCP ports `80`, `443`, `2222`, and `8080` are accessible on your GCP load balancers. See *Step 5: Create Firewall Rules for the Network* in [Preparing to Deploy Ops Manager on GCP Manually](#).
 3. Verify that you have configured the proper SSL certificates on your HTTP(S) load balancer in GCP. See *Step 8: Create HTTP Load Balancer* in [Preparing to Deploy Ops Manager on GCP Manually](#).
 4. If necessary, re-upload a new certificate and update any required SSL Certificate and SSH Key fields in your [PAS network configuration](#).
-

Insufficient External Database Permissions

Upgrade issues can be caused when the external database user used for the network policy DB is given insufficient permissions. To avoid this upgrade issue, ensure that the networkpolicyserver database user has the `ALL PRIVILEGES` permission.

Upgrading BOSH Director on GCP

This topic describes how to upgrade BOSH Director for Pivotal Cloud Foundry (PCF) on Google Cloud Platform (GCP).

Complete the tasks in this topic as part of the Ops Manager upgrade process. For more information, see [Upgrading Pivotal Cloud Foundry](#).

Overview

In this procedure, you create an Ops Manager VM instance to host the upgraded version of Ops Manager. Then, to complete the Ops Manager upgrade, you export your existing Ops Manager installation onto this new VM.

To create an Ops Manager VM instance, do the following tasks:

1. Locate the Ops Manager installation file. See [Locate the Pivotal Ops Manager Installation File](#).
2. Create a private VM image. See [Create a Private VM Image](#).
3. Create the Ops Manager VM. See [Create the Ops Manager VM Instance](#).

Prerequisites

To complete the Ops Manager upgrade, you must have your Ops Manager decryption passphrase. You defined this decryption passphrase during the initial installation of Ops Manager.

Locate the Pivotal Ops Manager Installation File

The Ops Manager installation file includes a filepath to the Ops Manager image. You use this image file to create a private VM image for the new Ops Manager VM.

To locate the Ops Manager installation file, do the following:

1. Log in to the [Pivotal Network](#), and click on **Pivotal Cloud Foundry Operations Manager**.
2. From the **Releases** drop-down, select the release for your upgrade.
3. Select one of the following download files:
 - **Pivotal Cloud Foundry Ops Manager for GCP**
 - **Pivotal Cloud Foundry Ops Manager YAML for GCP** When you click on the download link, your browser downloads or opens the `OpsManager_version_onGCP.pdf` or `OpsManager_version_onGCP.yml` file.

These documents provide the GCP location of the Ops Manager `.tar.gz` installation file based on the geographic location of your installation.

4. Copy the filepath string of the Ops Manager image based on your existing deployment location.

Create a Private VM Image

Create a private VM image to use when you create the new Ops Manager VM.

To create a private VM image, do the following:

1. Log in to the [GCP Console](#).
2. In the left navigation panel, click **Compute Engine**, and select **Images**.
3. Click **Create Image**.
4. Complete the following fields:

- **Name:** Enter a name that matches the naming convention of your existing Ops Manager image files.
- **Encryption:** Leave **Automatic (recommended)** selected.
- **Source:** Choose **Cloud Storage file**.
- **Cloud Storage file:** Paste in the Google Cloud Storage filepath you copied from the PDF or YAML file in the previous task.

Create an image

Name [?]
om-pcf

Cloud Storage file

Cloud Storage file [?]
☒ r-images/pivotal-ops-manager-20160916101000-010010.tar.gz

Equivalent [REST](#) or [command line](#)

5. Click **Create**. The file may take a few minutes to import.

Create the Ops Manager VM Instance

Create an Ops Manager VM instance to host the new version of Ops Manager.

To create an Ops Manager VM instance, do the following:

1. Select the checkbox for the image that you created above.

| Images | | | | |
|---|-------|------------|--------|---------------------------|
| + CREATE IMAGE REFRESH + CREATE INSTANCE DEPRECATE DELETE | | | | |
| <input type="text" value="Filter by label or name"/> <input type="button" value="Columns"/> <input type="button" value="Labels"/> | | | | |
| Name | Size | Created by | Family | Creation time |
| <input checked="" type="checkbox"/> om-pcf | 50 GB | CF-Docs | | Nov 22, 2016, 10:07:54 AM |

2. Click **Create Instance**.
3. In the **Create an instance form**, complete the following fields:
 - **Name:** Enter a name that matches the naming conventions of your existing deployment.
 - **Zone:** Choose a zone from the region of your existing deployment.
 - **Machine type:** Click **Customize** to manually configure the vCPU and memory. An Ops Manager VM instance requires the following minimum specifications:

| Machine Spec | Minimum Value |
|--------------|---------------|
| CPU | 2 vCPUs |
| Memory | 8 GB |

- **Boot disk:** Click **Change**, then perform the following steps:
 - Click **Custom images** if it is not already selected.
 - Select the **Boot disk type**. If you have an Ops Manager environment with high performance needs, select **SSD**. As an example,

environments used to [develop PCF tiles](#) may benefit from a higher performing Ops Manager VM boot disk. For most environments, however, you can select **Standard**.

- Set the **Size (GB)** of the boot disk to the minimum or higher.

| Machine Spec | Minimum Value |
|--------------|---------------|
| Boot disk | 100 GB |

- Select the Ops Manager image you created in the previous step if it is not already selected.

Boot disk

Select an image or snapshot to create a boot disk; or attach an existing disk.

OS images Application images **Custom images** Snapshots

Existing disks

☒ **om-pcf**
Created from CF-Docs on Oct 18, 2016, 11:38:02 AM

- Click **Select** to save.

- Under **Identity and API access**, choose the **Service account** you created when you initially installed Pivotal Cloud Foundry. See [Set up an IAM Service Account](#).
- **Allow HTTP traffic**: Only select this checkbox if you selected it in your original Ops Manager VM configuration.
- **Allow HTTPS traffic**: Only select this checkbox if you selected it in your original Ops Manager VM configuration.

Create

Cancel

- **Networking:** Select the **Networking** tab, and perform the following steps:
 - For **Network** and **Subnetwork**, select the network and subnetwork you created when you initially deployed Pivotal Cloud Foundry. See [Create a GCP Network with Subnet](#) section of the *Preparing to Deploy Ops Manager on GCP Manually* topic.
 - For **Network tags**, enter any tags that you applied to your original Ops Manager. For example, if you used the `pcf-opsmanager` tag to apply the firewall rule you created in [Create Firewall Rules for the Network](#), then apply the same tag to this Ops Manager VM.
 - For **Internal IP**, select `Custom`. In the **Internal IP address** field, enter a spare address located within the reserved IP range [configured in your existing BOSH Director](#). Do not use `10.0.0.1`, which is configured for the Gateway.
 - For **External IP**, select **New static IP address...**. In the next form, enter a name for the static IP. For example, `om-public-ip`. Click **Reserve**. In the **External IP** drop-down, select the static IP address you just reserved.

[Less](#)

4. Click **Create** to deploy the new Ops Manager VM. This may take a few moments.
5. Navigate to your DNS provider, and modify the entry that points a fully qualified domain name (FQDN) to the Ops Manager VM. Replace the original Ops Manager static IP address with the public IP address of the new Ops Manager VM you created in a previous step.

Note: In order to set up Ops Manager authentication correctly, Pivotal recommends using a Fully Qualified Domain Name (FQDN) to access Ops Manager. Using an ephemeral IP address to access Ops Manager can cause authentication errors upon subsequent access.

Next Steps

After you complete this procedure, continue the upgrade instructions in [Upgrading Pivotal Cloud Foundry](#) topic.

Later on, if you need to SSH into the Ops Manager VM to perform diagnostic troubleshooting, see [SSH into Ops Manager](#).

Installing Pivotal Cloud Foundry on OpenStack

Page last updated:

This guide describes how to install Pivotal Cloud Foundry (PCF) on OpenStack with Ops Manager and Pivotal Application Service (PAS).

Overview

OpenStack is a cloud operating system that controls large pools of compute, storage, and networking resources throughout a datacenter. For guidance on OpenStack service credential management, see [Open Stack Security Documents](#) below.

OpenStack Security Documents

These documents provide a general reference for OpenStack service credential management.

- [OpenStack credential configuration](#) 
- [OpenStack credential creation](#) 
- [OpenStack deployment configuration](#) 

Requirements

This section describes the requirements for installing PCF on OpenStack, including general requirements for installing PCF with Ops Manager and PAS as well as OpenStack requirements.

 **Note:** You can install PCF on OpenStack with the Pivotal Application Service (PAS) runtime. The Pivotal Container Service (PKS) runtime is not supported for OpenStack. For more information about PAS, see [PAS Concepts](#). For more information about PKS, see [Pivotal Container Service \(PKS\)](#) .

General Requirements

The following are general requirements for deploying and managing a PCF deployment with Ops Manager and Pivotal Application Service (PAS):

- A wildcard DNS record that points to your router or load balancer. Alternatively, you can use a service such as xip.io. For example, `203.0.113.0.xip.io`.
 - PAS gives each application its own hostname in your app domain.
 - With a wildcard DNS record, every hostname in your domain resolves to the IP address of your router or load balancer, and you do not need to configure an A record for each app hostname. For example, if you create a DNS record `*.example.com` pointing to your load balancer or router, every application deployed to the `example.com` domain resolves to the IP address of your router.
- At least one wildcard TLS certificate that matches the DNS record you set up above, `*.example.com`.
- Sufficient IP allocation:
 - One static IP address for either HAProxy or one of your gorouters
 - One static IP address for each job in the Ops Manager tile. See the Resource Config pane for each tile for a full list.
 - One static IP address for each job listed below:
 - Consul
 - NATS
 - File Storage
 - MySQL Proxy
 - MySQL Server
 - Backup Prepare Node
 - HAProxy
 - Router
 - MySQL Monitor
 - Diego Brain
 - TCP Router

- One IP for each VM instance created by the service.
- An additional IP address for each compilation worker. So the formula for total IPs needed is

`IPs needed = static IPs + VM instances + compilation workers`.

Note: Pivotal recommends that you allocate at least 36 dynamic IP addresses when deploying Ops Manager and PAS. BOSH requires additional dynamic IP addresses during installation to compile and deploy VMs, install PAS, and connect to services.

- One or more NTP servers if not already provided by your IaaS.
- (**Recommended**) A network without DHCP available for deploying the PAS VMs.

Note: If you have DHCP, refer to the [Troubleshooting Guide](#) to avoid issues with your installation.

- (**Optional**) External storage. When you deploy PCF, you can select internal file storage or external file storage, either network-accessible or IaaS-provided, as an option in the PAS tile. Pivotal recommends using external storage whenever possible. See [Configure File Storage](#) for a discussion of how file storage location affects platform performance and stability during upgrades.
- (**Optional**) External databases. When you deploy PCF, you can select internal or external databases for the BOSH Director and for PAS. Pivotal recommends using external databases in production deployments. An external database must be configured to use the UTC timezone.
- (**Optional**) External user stores. When you deploy PCF, you can select a SAML user store for Ops Manager or a SAML or LDAP user store for PAS, to integrate existing user accounts.
- The most recent version of the [Cloud Foundry Command Line Interface](#) (cf CLI).

OpenStack Requirements

The following are OpenStack requirements for deploying PCF:

- PCF is supported on the OpenStack Ocata, Pike, Queens, Rocky, and Stein releases. OpenStack is a collection of inter-operable components and requires general OpenStack expertise to troubleshoot issues that may occur when installing Pivotal Cloud Foundry on particular releases and distributions. To verify that your OpenStack platform is compatible with PCF, use the OpenStack Validator tool. To access the OpenStack Validator tool, see [CF OpenStack Validator](#) on GitHub.
- Pivotal recommends granting complete access to the OpenStack logs to the operator managing the PCF installation process.
- For OpenStack accounts for PCF, Pivotal recommends following the principle of least privilege by scoping privileges to the most restrictive permissions possible for a given role.
- You must have a dedicated OpenStack project, formerly known as an OpenStack tenant.
- You must have Keystone access to the dedicated OpenStack project, including the following:
 - Auth URL
 - Username and password. The `PrimaryProject` for the user must be the project you want to use to deploy PCF. For more information, see [Manage projects and users](#) in the OpenStack documentation.
 - Project name
 - Region (with multiple availability zones if you require high availability)
 - SSL certificate for your wildcard domain (see below)
- You must have the ability to do the following in OpenStack:
 - Create and modify VM flavors
 - Enable DHCP if required
 - Create a network and then connect that network with a router to an external network
 - Create an external network with a pool of floating IP addresses
 - Boot VMs directly from image
 - Create two wildcard domains for separate system and app domains
- The following are resource requirements for the dedicated OpenStack project:
 - 118 GB of RAM
 - 22 available instances
 - 16 small VMs (1 vCPU, 1024 MB of RAM, 10 GB of root disk)
 - 3 large VMs (4 vCPU, 16384 MB of RAM, 10 GB of root disk)
 - 3 extra-large VMs (8 vCPU, 16 GB of RAM, 160 GB of ephemeral disk)
 - 56 vCPUs
 - 1 TB of storage

- Nova or Neutron networking with floating IP support

 **Note:** By default, PAS deploys the number of VM instances required to run a highly available configuration of PCF. If you are deploying a test or sandbox PCF that does not require HA, then you can scale down the number of instances in your deployment. For information about the number of instances required to run a minimal, non-HA PCF deployment, see [Scaling PAS](#).

- The following are requirements for the OpenStack Cinder back-end:
 - PCF requires RAW root disk images. The Cinder back-end for your OpenStack project must support RAW.
 - Pivotal recommends that you use a Cinder back-end that supports snapshots. This is required for some BOSH functionalities.
 - Pivotal recommends enabling your Cinder back-end to delete block storage asynchronously. If this is not possible, it must be able to delete multiple 20 GB volumes within 300 seconds.
- The following are requirements for using an Overlay Network with VXLAN or GRE Protocols:
 - If an overlay network is being used with VXLAN or GRE protocols, the MTU of the created VMs must be adjusted to the best practices recommended by the plugin vendor (if any).
 - DHCP must be enabled in the internal network for the MTU to be assigned to the VMs automatically.
 - Review the [Deploying PAS on OpenStack](#) topic to adjust your MTU values.
 - Failure to configure your overlay network correctly could cause Apps Manager to fail since applications will not be able to connect to the UAA.

 **Note:** If you are using IPsec, your resource usage will increase by approximately 36 bytes. View the [Installing IPsec topic](#)  for information, including setting correct MTU values.

Install PCF on OpenStack with PAS

To install PCF on OpenStack with the PAS runtime, do the following:

1. Deploy Ops Manager. See [Deploying Ops Manager on OpenStack](#).
2. Configure BOSH Director on OpenStack. See [Configuring BOSH Director on OpenStack](#).
3. (Optional) Install the PCF IPsec add-on. See [\(Optional\) Installing the PCF IPsec Add-On](#) .
4. Configure PAS. See [Deploying PAS on OpenStack](#).

Deploying Ops Manager on OpenStack

Page last updated:

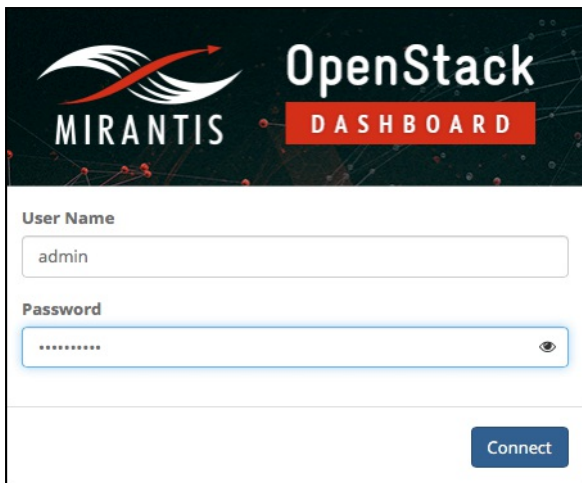

This guide describes how to provision the OpenStack infrastructure where you need to install [Pivotal Cloud Foundry](#). Use this topic when [Installing Pivotal Cloud Foundry on OpenStack](#).

After completing this procedure, complete all of the steps in the [Configuring BOSH Director on OpenStack](#) and [Deploying PAS on OpenStack](#) topics.

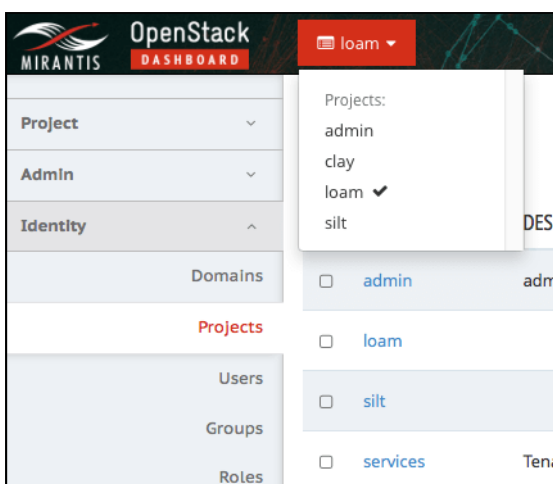

Note: This document uses Mirantis OpenStack for screenshots and examples. The screens of your OpenStack vendor configuration interface may differ.

Step 1: Log in to the OpenStack Horizon Dashboard

1. Log in to the OpenStack Horizon dashboard.

2. Click **Connect**.
3. From the OpenStack project list dropdown, set the active project by selecting the project where you will deploy PCF.

Step 2: Configure Security

Warning: If you are using OpenStack Liberty or Mitaka, do not create the key pair with the OpenStack Horizon dashboard. Instead make sure that you generate the SSH key pair manually. For example, use the `ssh-keygen` command. Then follow the procedure below to import that key pair into OpenStack. This is due to an [OpenStack bug](#).

1. In the left navigation of your OpenStack Horizon dashboard, click **Project > Compute > Access & Security**.
2. Select the **Key Pairs** tab on the **Access & Security** page.
3. Click **Import Key Pair**.
4. Enter a **Key Pair Name** and the contents of your public key in the **Public Key** field.

Import Key Pair

Key Pair Name *

Public Key *

ssh-rsa

AA

Description:

Key Pairs are how you login to your instance after it is launched.

Choose a key pair name you will recognise and paste your SSH public key into the space provided.

SSH key pairs can be generated with the ssh-keygen command:

```
ssh-keygen -t rsa -f cloud.key
```

This generates a pair of keys: a key you keep private (cloud.key) and a public key (cloud.key.pub). Paste the contents of the public key file here.

After launching an instance, you login using the private key (the username might be different depending on the image you launched):

```
ssh -i cloud.key <username>@<instance_ip>
```

5. Click **Import Key Pair**.
6. In the left navigation, click **Access & Security** to refresh the page. The new key pair appears in the list.
7. Select the **Security Groups** tab. Click **Create Security Group** and create a group with the following properties:
 - **Name:**
 - **Description:**

Create Security Group

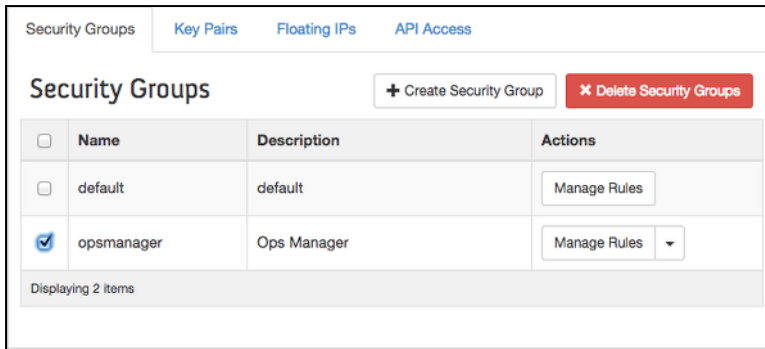

Name *

Description *

Description:

Security groups are sets of IP filter rules that are applied to the network settings for the VM. After the security group is created, you can add rules to the security group.

8. Select the checkbox for the Security Group and click **Manage Rules**.

9. Add the following ingress access rules for HTTP, HTTPS, and SSH as shown in the table below. The rules with `opsmanager` in the Remote column have restricted access to that particular Security Group.

Note: Adjust the remote sources as necessary for your own security compliance. Pivotal recommends limiting remote access to Ops Manager to IP ranges within your organization.

| Direction | Ether Type | IP Protocol | Port/Port Range | Remote |
|-----------|------------|-------------|-----------------|------------------|
| Ingress | IPv4 | TCP | 22 (SSH) | 0.0.0.0/0 (CIDR) |
| Ingress | IPv4 | TCP | 80 (HTTP) | 0.0.0.0/0 (CIDR) |
| Ingress | IPv4 | TCP | 443 (HTTPS) | 0.0.0.0/0 (CIDR) |
| Ingress | IPv4 | TCP | 25555 | 0.0.0.0/0 (CIDR) |
| Ingress | IPv4 | TCP | 1-65535 | opsmanager |
| Ingress | IPv4 | UDP | 1-65535 | opsmanager |

10. Leave the existing default egress access rules as shown in the screenshot below.

Access & Security

/ Manage Security Group Rules: opsmanager (af1 [redacted])

+ Add Rule X Delete Rules

| <input type="checkbox"/> | DIRECTION | ETHER TYPE | IP PROTOCOL | PORT RANGE | REMOTE IP PREFIX | REMOTE SECURITY GROUP | ACTIONS |
|--------------------------|-----------|------------|-------------|-------------|------------------|-----------------------|-------------|
| <input type="checkbox"/> | Egress | IPv4 | Any | Any | 0.0.0.0/0 | - | Delete Rule |
| <input type="checkbox"/> | Egress | IPv6 | Any | Any | ::/0 | - | Delete Rule |
| <input type="checkbox"/> | Ingress | IPv4 | TCP | 1 - 65535 | - | opsmanager | Delete Rule |
| <input type="checkbox"/> | Ingress | IPv4 | TCP | 22 (SSH) | 0.0.0.0/0 | - | Delete Rule |
| <input type="checkbox"/> | Ingress | IPv4 | TCP | 80 (HTTP) | 0.0.0.0/0 | - | Delete Rule |
| <input type="checkbox"/> | Ingress | IPv4 | TCP | 443 (HTTPS) | 0.0.0.0/0 | - | Delete Rule |
| <input type="checkbox"/> | Ingress | IPv4 | TCP | 25555 | 0.0.0.0/0 | - | Delete Rule |
| <input type="checkbox"/> | Ingress | IPv4 | UDP | 1 - 65535 | - | opsmanager | Delete Rule |

Displaying 8 items

Step 3: (Optional) Run the CF OpenStack Validator Tool

As an optional but recommended step, you can now run the CF OpenStack Validator tool against your OpenStack tenant to verify support for PCF.

- Follow the directions for running the [CF OpenStack Validator Tool](#).
- When configuring the CPI version used by the Validator, specify the OpenStack CPI version indicated in the [PCF Ops Manager Release Notes](#) for

the PCF release that you are planning to deploy.

Troubleshooting the output of the CF OpenStack Validator tool is beyond the scope of this document.

Step 4: Create Ops Manager Image

You can create the Ops Manager image in OpenStack using the OpenStack Horizon dashboard.

 **Note:** If your Horizon Dashboard does not support file uploads, you must use the [Glance CLI](#) client.

To create an Ops Manager image in OpenStack, do the following:

1. Download the **Pivotal Cloud Foundry Ops Manager for OpenStack** image file from [Pivotal Network](#).
2. In the left navigation of your OpenStack dashboard, click **Project > Compute > Images**.
3. Click **Create Image**. Complete the **Create An Image** page with the following information:
 - **Name:** Enter `Ops Manager`.
 - **Image Source:** Select **Image File**.
 - **Image File:** Click **Choose File**. Browse to and select the image file that you downloaded from [Pivotal Network](#).
 - **Format:** Select **Raw**.
 - **Minimum Disk (GB):** Enter `80`.
 - **Minimum RAM (MB):** Enter `8192`.
 - Deselect the **Public** checkbox.
 - Select the **Protected** checkbox.

Create Image

Description:

Currently only images available via an HTTP/HTTPS URL are supported. The image location must be accessible to the Image Service.

Please note: The Image Location field MUST be a valid and direct URL to the image binary. URLs that redirect or serve error pages will result in unusable images.

4. Click **Create Image**.

Step 5: Launch Ops Manager VM

1. In the left navigation of your OpenStack dashboard, click **Project > Compute > Images**.
2. Click **Launch**.

| Images | | | | | | | | |
|-------------------------------------|------------------|-------|--------|--------|-----------|--------|--------|-----------------|
| | | | | | | | | + Create Image |
| | | | | | | | | ✕ Delete Images |

- Click **Associate**.

Step 7: Add Blob Storage

- In the left navigation of your OpenStack dashboard, click **Project > Object Store > Containers**.
- Click **Create Container**. Create a container with the following properties:
 - Container Name:** Enter `pcf`.
 - Container Access:** Leave **public** unselected.

Create Container

Container Name *

Container Access

☐ Public

A container is a storage compartment for your data and provides a way for you to organize your data. You can think of a container as a folder in Windows® or a directory in UNIX®. The primary difference between a container and these other file system concepts is that containers cannot be nested. You can, however, create an unlimited number of containers within your account. Data must be stored in a container so you must have at least one container defined in your account prior to uploading data.

Note: A Public Container will allow anyone with the Public URL to gain access to your objects in the container.

✕ Cancel

+ Create

- Click **Create**.

Step 8: Download Credentials for S3 Blob Storage

- In the left navigation of your OpenStack dashboard, click **Project > Compute > Access & Security**. Select the **API Access** tab.

| Compute | http://213.146.132.100:8774/v2.0 |
| Network | http://213.146.132.100/ |

- Click **Download EC2 Credentials**.
- Unzip the downloaded credentials.
- If you select **S3 Compatible Blobstore** in your [BOSH Director Config](#), you need the contents of this file to complete the configuration.

Step 9: Create a DNS Entry

Note: For security, Ops Manager v1.7 and later require you to create a fully qualified domain name in order to access Ops Manager during the [initial configuration](#).

Create a DNS entry for the floating IP address that you assigned to Ops Manager in [Step 6: Associate a Floating IP Address](#).

You must use this fully qualified domain name when you log into Ops Manager for the first time.

Step 10: Configure BOSH Director for OpenStack

After completing this procedure, complete all of the steps in the [Configuring BOSH Director on OpenStack](#) and [Deploying PAS on OpenStack](#) topics.

Return to [Installing Pivotal Cloud Foundry on OpenStack](#).

Configuring BOSH Director on OpenStack

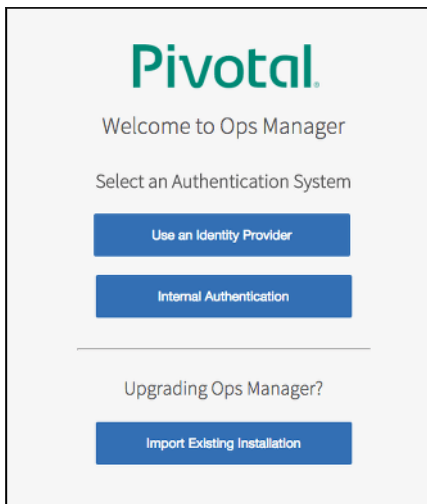

This topic describes how to configure BOSH Director after deploying [Pivotal Cloud Foundry](#) (PCF) on OpenStack. Use this topic when [Installing Pivotal Cloud Foundry on OpenStack](#).

- Before beginning this procedure, ensure that you have successfully completed all steps in [Provisioning the OpenStack Infrastructure](#).
- After you complete this procedure, follow the instructions in [Deploying PAS on OpenStack](#).

 **Note:** You can also perform the procedures in this topic using the Ops Manager API. For more information, see [Using the Ops Manager API](#).

Step 1: Access Ops Manager

1. In a web browser, navigate to the fully qualified domain you created in the [Create a DNS Entry](#) step of *Provisioning the OpenStack Infrastructure*.
2. When Ops Manager starts for the first time, you must choose one of the following:
 - [Use an Identity Provider](#): If you choose **Use an Identity Provider**, an external identity server maintains your user database.
 - [Internal Authentication](#): If you choose **Internal Authentication**, Ops Manager maintains your user database.

Use an Identity Provider

1. Log in to your IdP console and download the IdP metadata XML. Optionally, if your IdP supports metadata URL, you can copy the metadata URL instead of the XML.

2. Copy the IdP metadata XML or URL to the Ops Manager **Use an Identity Provider** login page.

Note: The same IdP metadata URL or XML is applied for the BOSH Director. If you use a separate IdP for BOSH, copy the metadata XML or URL from that IdP and enter it into the BOSH IdP Metadata text box in the Ops Manager login page.

3. Enter values for the fields listed below. Failure to provide values in these fields results in a `500` error.

Note: These attributes are case-sensitive.

- **SAML admin group:** Enter the name of the SAML group that contains all Ops Manager administrators.
- **SAML groups attribute:** Enter the groups attribute tag name with which you configured the SAML server.

4. Enter your **Decryption passphrase**. Read the **End User License Agreement**, and select the checkbox to accept the terms.

5. Your Ops Manager login page appears. Enter your username and password. Click **Login**.

6. Download your SAML Service Provider metadata (SAML Relying Party metadata) by navigating to the following URLs:

- **6a.** Ops Manager SAML service provider metadata: `https://OPS-MAN-FQDN:443/uaa/saml/metadata`
- **6b.** BOSH Director SAML service provider metadata: `https://BOSH-IP-ADDRESS:8443/saml/metadata`

Note: To retrieve your `BOSH-IP-ADDRESS`, navigate to the **BOSH Director** tile > **Status** tab. Record the **BOSH Director** IP address.

7. Configure your IdP with your SAML Service Provider metadata. Import the Ops Manager SAML provider metadata from Step 6a above to your IdP. If your IdP does not support importing, provide the values below.

- **Single sign on URL:** `https://OPS-MAN-FQDN:443/uaa/saml/SSO/alias/OPS-MAN-FQDN`
- **Audience URI (SP Entity ID):** `https://OP-MAN-FQDN:443/uaa`
- **Name ID:** Email Address
- SAML authentication requests are always signed

8. Import the BOSH Director SAML provider metadata from Step 6b to your IdP. If the IdP does not support an import, provide the values below.

- **Single sign on URL:** `https://BOSH-IP:8443/saml/SSO/alias/BOSH-IP`
- **Audience URI (SP Entity ID):** `https://BOSH-IP:8443`
- **Name ID:** Email Address
- SAML authentication requests are always signed

9. Return to the **BOSH Director** tile, and continue with the configuration steps below.

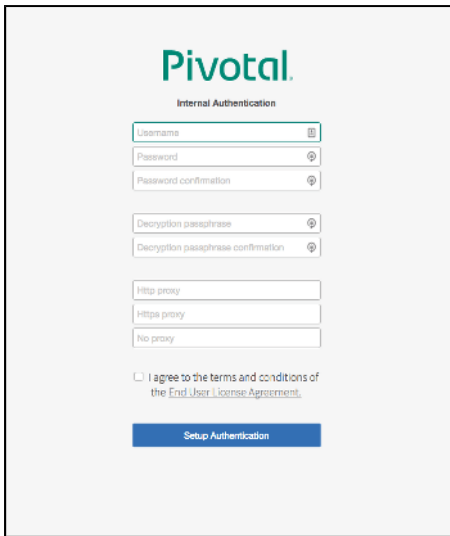

Use Internal Authentication

1. When redirected to the **Internal Authentication** page, do the following:

- Enter a **Username**, **Password**, and **Password confirmation** to create an Admin user.
- Enter a **Decryption passphrase** and the **Decryption passphrase confirmation**. This passphrase encrypts the Ops Manager datastore, and is not

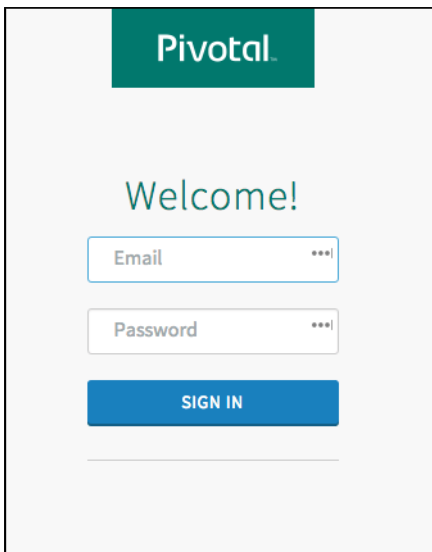

recoverable.

- If you are using an **HTTP proxy** or **HTTPS proxy**, follow the instructions in [Configuring Proxy Settings for the BOSH CPI](#).
- Read the **End User License Agreement**, and select the checkbox to accept the terms.
- Click **Setup Authentication**.

The screenshot shows the 'Internal Authentication' setup page in Pivotal. It features the Pivotal logo at the top. Below the logo, there are several input fields: 'Username', 'Password', 'Password confirmation', 'Decryption passphrase', and 'Decryption passphrase confirmation'. Each of these fields has a small icon to its right. Below these fields are three radio button options for 'Http proxy': 'Http proxy', 'Https proxy', and 'No proxy'. At the bottom, there is a checkbox labeled 'I agree to the terms and conditions of the End User License Agreement' and a blue button labeled 'Setup Authentication'.

2. Log in to Ops Manager with the Admin username and password you created in the previous step.

The screenshot shows the 'Welcome!' login page in Pivotal. It features the Pivotal logo at the top. Below the logo, the word 'Welcome!' is displayed. There are two input fields: 'Email' and 'Password', each with a small icon to its right. Below these fields is a blue button labeled 'SIGN IN'.

Step 2: OpenStack Config Page

1. In the left navigation of your OpenStack dashboard, click **Project > Compute > Access & Security**. Select the **API Access** tab.
2. Record the **Service Endpoint** for the **Identity** service. You use this Service Endpoint as the Authentication URL for Ops Manager in a later step.

☐ Enable VM Resurrector Plugin

☐ Enable Post Deploy Scripts

☐ Recreate all VMs

This will force BOSH to recreate all VMs on the next deploy. Persistent disk will be preserved

☐ Enable bosh deploy retries

This will attempt to re-deploy a failed deployment up to 5 times.

☐ Keep Unreachable Director VMs

- Enter one or more NTP servers in the **NTP Servers (comma delimited)** field. For example, `us.pool.ntp.org`.

Note: The NTP server configuration only updates after VM recreation. Ensure that you select the **Recreate all VMs** checkbox if you modify the value of this field.

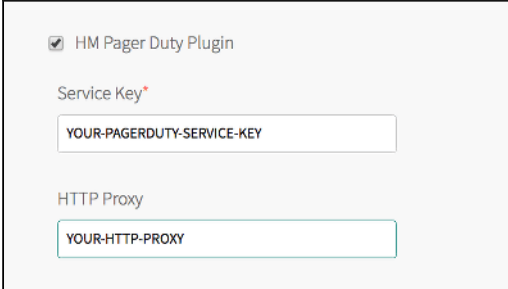

- Leave the **JMX Provider IP Address** field blank.

Note: Starting in PCF v2.0, BOSH-reported component metrics are available in the Loggregator Firehose by default. If you continue to use PCF JMX Bridge to consume these component metrics outside of the Firehose, you may receive duplicate data. To prevent this, leave the **JMX Provider IP Address** field blank. For additional guidance, see [BOSH System Metrics Available in Loggregator Firehose](#) in the PCF v2.0 Release Notes.

4. Leave the **Bosh HM Forwarder IP Address** field blank.

Note: Starting in PCF v2.0, BOSH-reported component metrics are available in the Loggregator Firehose by default. If you continue to use the BOSH HM Forwarder to consume these component metrics, you may receive duplicate data. To prevent this, leave the **Bosh HM Forwarder IP Address** field blank. For additional guidance, see [BOSH System Metrics Available in Loggregator Firehose](#) in the PCF v2.0 Release Notes.

5. Select the **Enable VM Resurrector Plugin** checkbox to enable the Ops Manager Resurrector functionality and increase PAS availability.
6. Select **Enable Post Deploy Scripts** to run a post-deploy script after deployment. This script allows the job to execute additional commands against a deployment.
7. Select **Recreate all VMs** to force BOSH to recreate all VMs on the next deploy. This process does not destroy any persistent disk data.
8. Select **Enable bosh deploy retries** to instruct Ops Manager to retry failed BOSH operations up to five times.
9. (Optional) Disable **Allow Legacy Agents** if all of your tiles have stemcells v3468 or later. Disabling the field will allow Ops Manager to implement TLS secure communications.
10. Select **Keep Unreachable Director VMs** if you want to preserve BOSH Director VMs after a failed deployment for troubleshooting purposes.

The screenshot shows a configuration form for the 'HM Pager Duty Plugin'. It includes a checked checkbox for the plugin name, a 'Service Key' field with a red asterisk and a placeholder 'YOUR-PAGERDUTY-SERVICE-KEY', and an 'HTTP Proxy' field with a placeholder 'YOUR-HTTP-PROXY'.

11. Select **HM Pager Duty Plugin** to enable Health Monitor integration with PagerDuty.

- **Service Key:** Enter your API service key from PagerDuty.
- **HTTP Proxy:** Enter an HTTP proxy for use with PagerDuty.

☒ HM Email Plugin

☒ Enable TLS

12. Select **HM Email Plugin** to enable Health Monitor integration with email.

- **Host:** Enter your email hostname.
- **Port:** Enter your email port number.
- **Domain:** Enter your domain.
- **From:** Enter the address for the sender.
- **Recipients:** Enter comma-separated addresses of intended recipients.
- **Username:** Enter the username for your email server.
- **Password:** Enter the password for your email server.
- **Enable TLS:** Select this checkbox to enable Transport Layer Security.

13. For **CredHub Encryption Provider**, you can choose whether BOSH CredHub stores its encryption key internally on the BOSH Director and CredHub VM, or in an external hardware security module (HSM). The HSM option is more secure.

Before configuring an HSM encryption provider in the **Director Config** pane, you must follow the procedures and collect information described in [Preparing CredHub HSMs for Configuration](#).

 **Note:** After you deploy Ops Manager with an HSM encryption provider, you cannot change BOSH CredHub to store encryption keys internally.

CredHub Encryption Provider

☒ Internal
 ☐ Luna HSM

Encryption Key Name*

Provider Partition*

Provider Partition Password*

Provider Client Certificate*

Provider Client Certificate Private Key*

HSM Host Address*

HSM Port Address*

Partition Serial Number*

HSM Certificate*

- **Internal:** Select this option for internal CredHub key storage. This option is selected by default and requires no additional configuration.
- **Luna HSM:** Select this option to use a SafeNet Luna HSM as your permanent CredHub encryption provider, and fill in the following fields:
 1. **Encryption Key Name:** Any name to identify the key that the HSM uses to encrypt and decrypt the CredHub data. Changing this key name after you deploy Ops Manager can cause service downtime.
 2. **Provider Partition:** The partition that stores your encryption key. Changing this partition after you deploy Ops Manager could cause service downtime. For this value and the ones below, use values gathered in [Preparing CredHub HSMs for Configuration](#).
 3. **Provider Partition Password**
 4. **Provider Client Certificate:** The certificate that validates the identity of the HSM when CredHub connects as a client.
 5. **Provider Client Certificate Private Key**
 6. **HSM Host Address**
 7. **HSM Port Address:** If you do not know your port address, enter `1792`.
 8. **Partition Serial Number**
 9. **HSM Certificate:** The certificate that the HSM presents to CredHub to establish a two-way mTLS connection.

14. Select a **Blobstore Location** to either configure the blobstore as an internal server or an external endpoint. Because the internal server is unscalable and less secure, Pivotal recommends that you configure an external blobstore.

 **Note:** After you deploy Ops Manager, you cannot change the blobstore location.

Blobstore Location

☒ Internal
☐ S3 Compatible Blobstore

S3 Endpoint*

Bucket Name*

Access Key*

Secret Key*

☒ V2 Signature
☐ V4 Signature

Region*

☐ GCS Blobstore

Bucket Name*

Storage Class*

Regional

Service Account Key*

- o **Internal:** Select this option to use an internal blobstore. Ops Manager creates a new VM for blob storage. No additional configuration is required.
- o **S3 Compatible Blobstore:** Select this option to use an external S3-compatible endpoint. Follow the procedures in [Sign up for Amazon S3](#) and [Creating a Bucket](#) in the AWS documentation. When you have created an S3 bucket, complete the following steps:
 1. **S3 Endpoint:** Navigate to the [Regions and Endpoints](#) topic in the AWS documentation.
 - a. Locate the endpoint for your region in the **Amazon Simple Storage Service (S3)** table and construct a URL using your region's endpoint. For example, if you are using the `us-west-2` region, the URL you create would be `https://s3-us-west-2.amazonaws.com`. Enter this URL into the **S3 Endpoint** field.
 - b. On a command line, run `ssh ubuntu@OPS-MANAGER-FQDN` to SSH into the Ops Manager VM. Replace `OPS-MANAGER-FQDN` with the fully qualified domain name of Ops Manager.
 - c. Copy the custom public CA certificate you used to sign the S3 endpoint into `/etc/ssl/certs` on the Ops Manager VM.
 - d. On the Ops Manager VM, run `sudo update-ca-certificates -f -v` to import the custom CA certificate into the Ops Manager VM truststore.

 **Note:** You must also add this custom CA certificate into the **Trusted Certificates** field in the **Security** page. See [Security Page](#) for instructions.

2. **Bucket Name:** Enter the name of the S3 bucket.
3. **Access Key** and **Secret Key:** Enter the keys you generated when creating your S3 bucket.
4. Select **V2 Signature** or **V4 Signature**. If you select **V4 Signature**, enter your **Region**.

 **Note:** AWS recommends using Signature Version 4. For more information about AWS S3 Signatures, see [Authenticating Requests](#) in the AWS documentation.

- **Enable TLS:** Select this checkbox to enable TLS.

 **Note:** If you are using Linux stemcells, make sure you have configured [Linux stemcell v3586.16 or later](#) for all tiles before enabling TLS.

 **Note:** If you are using PAS for Windows 2016, make sure you have configured [Windows stemcell v1709.10 or later](#) for all tiles before enabling TLS.

- **GCS Blobstore:** Select this option to use an external GCS endpoint. To create a GCS bucket, you must have a GCS account. Follow the procedures in [Creating Storage Buckets](#) in the GCS documentation to create a GCS bucket. When you have created a GCS bucket, complete the following steps:
 1. **Bucket Name:** Enter the name of your GCS bucket.
 2. **Storage Class:** Select the storage class for your GCS bucket. See [Storage Classes](#) in the GCP documentation for more information.
 3. **Service Account Key:** Follow the steps in the [Set up an IAM Service Account](#) section of *Preparing to Deploy Ops Manager on GCP Manually* to download a JSON file with a private key. Enter the contents of the JSON file into the field.

15. Select a **Database Location**. By default, Ops Manager deploys and manages a database for you. If you choose to use an **External MySQL Database**, complete the associated fields with information obtained from your external MySQL Database provider.

Database Location

☒ Internal

☐ External MySQL Database

Host*

Port*

Username*

Password*

Database*

In addition, if you selected the **Enable TLS**

for **Director Database** checkbox, you can complete the following optional fields:

- **Enable TLS:** Select this checkbox to enables TLS communication between the BOSH Director and the database.
- **TLS CA:** Enter the Certificate Authority for the TLS Certificate.
- **TLS Certificate:** Enter the client certificate for mutual TLS connections to the database.
- **TLS Private Key:** Enter the client private key for mutual TLS connections to the database.
- **Advanced DB Connection Options:** If you would like to provide additional options for the database, use this field to provide a JSON-formatted options string.

16. (Optional) **Director Workers:** Set the number of workers available to execute Director tasks. This field defaults to .

17. (Optional) **Max Threads:** Enter the number of operations the BOSH Director can perform simultaneously.

18. (Optional) **Director Hostname:** Enter a valid hostname to add a custom URL for your BOSH Director. You can also use this field to configure a load balancer in front of your BOSH Director. For more information, see [How to Set Up a Load Balancer in Front of Operations Manager Director](#) in the Pivotal Support documentation.

⚠ warning: In Ops Manager v2.2.7 and earlier, if you change the **Director Hostname** after your initial deployment, VMs become unavailable. This causes PCF downtime. To restore VM availability, enable **Recreate All VMs** and redeploy. This issue is resolved in [Ops Manager v2.2.8](#) and later.

19. (Optional) Enter your list of comma-separated **Excluded Recursors** to declare which IP addresses and ports should not be used by the DNS server.
20. (Optional) To disable BOSH DNS, select the **Disable BOSH DNS server for troubleshooting purposes** checkbox. For more information about the BOSH DNS service discovery mechanism, see [BOSH DNS Enabled by Default](#) in the Ops Manager v2.2 Release Notes.

⚡ Breaking Change: Do not disable BOSH DNS without consulting Pivotal Support.

21. (Optional) **Custom SSH Banner:** Enter text to set a custom banner that users see when logging in to the Director using SSH.

☐ Disable BOSH DNS server for troubleshooting purposes

Custom SSH Banner

22. (Optional) Enter your comma-separated custom **Identification Tags**. For example, `iaas:foundation1, hello:world`. You can use the tags to identify your foundation when viewing VMs or disks from your IaaS.
23. Click **Save**.

💡 Note: If you select to use an internal database, back up your data frequently. For more information, see [Backing Up and Restoring Pivotal Cloud Foundry](#).

Step 5: Create Availability Zones Page

1. In Ops Manager, select **Create Availability Zones**.

Create Availability Zones

Availability Zones

▼ novaOpenstack Availability Zone*

nova

Save

2. Enter the name of the availability zone that you selected in the [Launch Ops Manager VM](#) step of *Provisioning the OpenStack Infrastructure*
3. Click **Save**.

Step 6: Create Networks Page

1. In the left navigation of your OpenStack dashboard, click **Project > Network > Networks**.

- Click the name of the network that contains the private subnet where you deployed the Ops Manager VM. The OpenStack Network Detail page displays your network settings.

[Networks](#) / loam_net Edit Network ▾

Network Overview

| | |

Add Network

Add Subnet

Save

- Select **Enable ICMP checks** to enable ICMP on your networks. Ops Manager uses ICMP checks to confirm that components within your network are reachable. Review the [Configure Security](#) step of *Deploying BOSH and Ops Manager to OpenStack* to ensure you have configured ICMP in your Security Group.
- Use the following steps to create one or more Ops Manager networks using information from your OpenStack network:
 - Click **Add Network**.
 - Enter a unique **Name** for the network.
 - Click **Add Subnet** to create one or more subnets for the network.
 - For **Network ID**, use the **ID** from the OpenStack page.
 - For **CIDR**, use the **Network Address** from the OpenStack page.
 - For **Reserved IP Ranges**, use the first 10 IP addresses of the **Network Address** range, and the private IP address of the Ops Manager instance that you recorded in the [Associate a Floating IP Address](#) step of *Provisioning the OpenStack Infrastructure*.
 - For **DNS**, enter one or more Domain Name Servers.
 - For **Gateway**, use the **Gateway IP** from the OpenStack page.
 - For **Availability Zones**, select which Availability Zones to use with the network.

- Click **Save**.

Note: After you deploy Ops Manager, you add subnets with overlapping Availability Zones to expand your network. For more information about configuring additional subnets, see [Expanding Your Network with Additional Subnets](#).

Step 7: Assign AZs and Networks Page

- Select **Assign Availability Zones**.

Assign AZs and Networks

The Ops Manager Director is a single instance.

Choose the availability zone in which to place that instance. It is highly recommended that you backup this VM on a regular basis to preserve settings.

Singleton Availability Zone

nova

Network

loam

Save

- From the **Singleton Availability Zone** dropdown, select the availability zone that you created in a previous step. The BOSH Director installs in this Availability Zone.
- Use the dropdown to select the **Network** that you created in a previous step. BOSH Director installs in this network.
- Click **Save**.

Step 8: Security Page

Security

Trusted Certificates

-----BEGIN CERTIFICATE-----

TH

These certificates enable BOSH-deployed components to trust a custom root certificate.

Generate VM passwords or use single password for all VMs

☒ Generate passwords
 ☐ Use default BOSH password

Save

- Select **Security**.

2. In **Trusted Certificates**, enter your custom certificate authority (CA) certificates to insert into your organization's certificate trust chain. This feature enables all BOSH-deployed components in your deployment to trust custom root certificates.

To enter multiple certificates, paste your certificates one after the other. For example, format your certificates like the following:

```
-----BEGIN CERTIFICATE-----
ABCDEF12345678ABCDEF12345678ABCDEF12345678AB
EFGH12345678ABCDEF12345678ABCDEF12345678ABCDEF
GH12345678ABCDEF12345678ABCDEF12345678...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
BCDEF12345678ABCDEF12345678ABCDEF12345678ABB
EFGH12345678ABCDEF12345678ABCDEF12345678ABCDEF
GH12345678ABCDEF12345678ABCDEF12345678...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
CDEF12345678ABCDEF12345678ABCDEF12345678ABBB
EFGH12345678ABCDEF12345678ABCDEF12345678ABCDEF
GH12345678ABCDEF12345678ABCDEF12345678...
-----END CERTIFICATE-----
```

Note: If you want to use Docker Registries for running app instances in Docker containers, enter the certificate for your private Docker Registry in this field. See [Using Docker Registries](#) for more information on running app instances in PAS using Docker Registries.

3. Choose **Generate passwords** or **Use default BOSH password**. Pivotal recommends that you use the **Generate passwords** option for greater security.
4. Click **Save**. To view your saved Director password, click the **Credentials** tab.

Step 9: Syslog Page

1. Select **Syslog**.

Syslog

Do you want to configure Syslog for Bosh Director?

☐ No
 ☒ Yes

Address*

The address or host for the syslog server

Port*

Transport Protocol*

TCP

⌵

☐ Enable TLS

Permitted Peer*

SSL Certificate*

Save

- (Optional) Select **Yes** to send BOSH Director system logs to a remote server.
- In the **Address** field, enter the IP address or DNS name for the remote server.
- In the **Port** field, enter the port number that the remote server listens on.
- In the **Transport Protocol** dropdown menu, select **TCP**, **UDP**, or **REL**. This selection determines which transport protocol is used to send the logs to the remote server.
- (Optional) Pivotal strongly recommends that you enable TLS encryption when forwarding logs as they may contain sensitive information. For example, these logs may contain cloud provider credentials. To enable TLS, perform the following steps.
 - In the **Permitted Peer** field, enter either the name or SHA1 fingerprint of the remote peer.
 - In the **SSL Certificate** field, enter the SSL certificate for the remote server.
- Click **Save**.

Step 10: Resource Config Page

- Select **Resource Config**.

Resource Config

| JOB | INSTANCES | PERSISTENT DISK TYPE | VM TYPE |
|------------------------|--------------|----------------------|---|
| Ops Manager Director | Automatic: 1 | Automatic: 50 GB | Automatic: medium.disk (cpu: 2, ram: 4 GE |
| Master Compilation Job | Automatic: 4 | None | Automatic: large.cpu (cpu: 4, ram: 4 GB, di |

Save

- Adjust any values as necessary for your deployment, such as increasing the persistent disk size. Select **Automatic** from the dropdown to provision the amount of persistent disk predefined by the job. If the persistent disk field reads **None**, the job does not require persistent disk space.

Note: Ops Manager requires a Director VM with at least 8 GB memory.

Note: If you set a field to **Automatic** and the recommended resource allocation changes in a future version, Ops Manager automatically uses the updated recommended allocation.

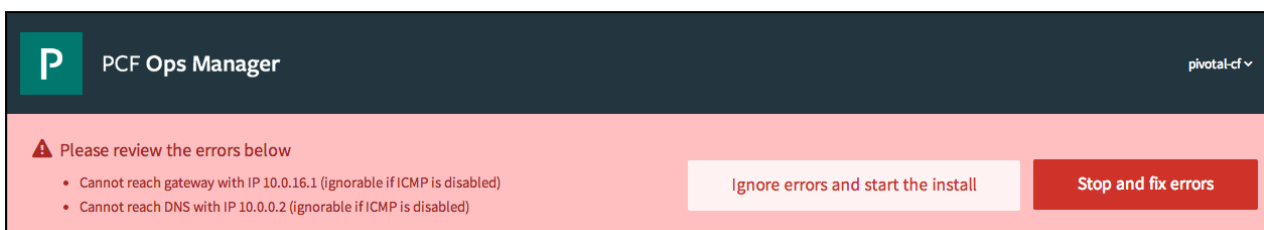

- Click **Save**.

Step 11: (Optional) Add Custom VM Extensions

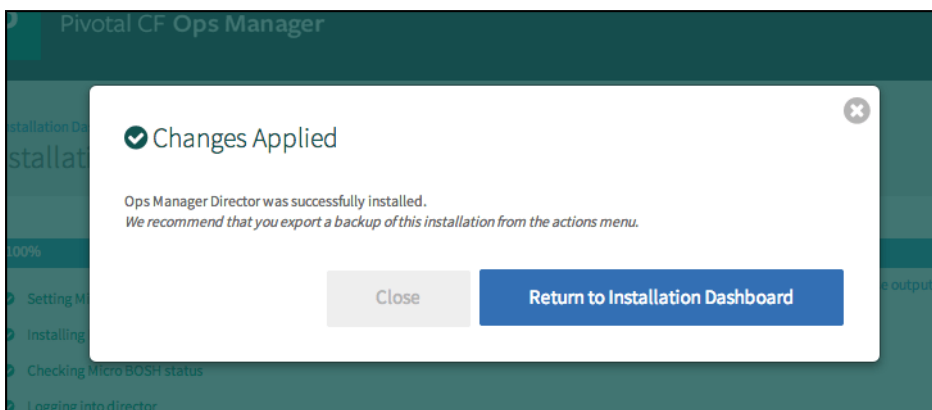

Use the Ops Manager API to add custom properties to your VMs such as associated security groups and load balancers. For more information, see [Managing Custom VM Extensions](#).

Step 12: Complete BOSH Director Installation

- Click the **Installation Dashboard** link to return to the Installation Dashboard.
- Click **Apply Changes**. If the following ICMP error message appears, click **Ignore errors and start the install**.

- BOSH Director installs. The image shows the **Changes Applied** message that Ops Manager displays when the installation process successfully completes.

4. After you complete this procedure, follow the instructions in [Deploying PAS on OpenStack](#).

Return to [Installing Pivotal Cloud Foundry on OpenStack](#).

Deploying PAS on OpenStack

Page last updated:

This topic describes how to install and configure Pivotal Application Service (PAS) after deploying [Pivotal Cloud Foundry](#) (PCF) on OpenStack.

Use this topic when [Installing Pivotal Cloud Foundry on OpenStack](#).

Before beginning this procedure, ensure that you have successfully completed all steps in the [Provisioning the OpenStack Infrastructure](#) topic and the [Configuring BOSH Director on OpenStack](#) topics.

Step 1: Add PAS to Ops Manager

1. If you have not already downloaded PAS, log in to [Pivotal Network](#), and click PAS.
2. From the **Releases** drop-down, select the release to install and choose one of the following:
 - a. Click PAS to download the PAS `.pivotal` file.
 - b. Click **PCF Small Footprint Runtime** to download the Small Footprint Runtime `.pivotal` file. For more information, see [Getting Started with Small Footprint Runtime](#).
3. Navigate to the Pivotal Cloud Foundry Operations Manager Installation Dashboard.
4. Click the Pivotal Network link on the left to add PAS to Ops Manager. For more information, refer to the [Adding and Deleting Products](#) topic.

Step 2: Assign Availability Zones and Networks

Note: Pivotal recommends at least three Availability Zones for a highly available installation of PAS.

1. Select **Assign AZ and Networks**. These are the Availability Zones that you [create](#) when configuring BOSH Director.
2. Select an Availability Zone under **Place singleton jobs**. Ops Manager runs any job with a single instance in this Availability Zone.
3. Select one or more Availability Zones under **Balance other jobs**. Ops Manager balances instances of jobs with more than one instance across the Availability Zones that you specify.
4. From the **Network** dropdown, choose the network on which you want to run PAS.

The screenshot shows the 'Pivotal Application Service' settings interface. At the top, there's a navigation bar with 'Settings', 'Status', 'Credentials', and 'Logs'. The 'Settings' tab is active. Below it, a list of settings categories is shown on the left, each with a green checkmark: 'Assign AZs and Networks', 'Domains', 'Networking', 'Application Containers', 'Application Developer Controls', 'Application Security Groups', 'Authentication and Enterprise SSO', and 'Databases'. The 'Assign AZs and Networks' category is selected, and its details are shown on the right. The title 'AZ and Network Assignments' is at the top of this section. It contains two radio buttons for 'Place singleton jobs in': 'first-az' (selected) and 'Balance other jobs in'. Below this, there's a checkbox for 'first-az' under 'Balance other jobs in', which is checked. A 'Network' dropdown menu is set to 'first-network'. A blue 'Save' button is at the bottom right of this section.

5. Click **Save**.

Note: When you save this form, a verification error displays because the PCF security group blocks ICMP. You can ignore this error.

The screenshot shows a red error message box from 'PCF Ops Manager'. It contains a warning icon and the text 'Please review the errors below'. The errors listed are: 'Cannot reach gateway with IP 10.0.16.1 (ignorable if ICMP is disabled)' and 'Cannot reach DNS with IP 10.0.0.2 (ignorable if ICMP is disabled)'. It concludes with 'All errors will be reverified before installation.'

Step 3: Configure Domains

1. Select **Domains**.

The screenshot shows the 'Configure Domains' form. It has a text box explaining: 'Elastic Runtime hosts applications at subdomains under its apps domain and assigns system components to subdomains under its system domain. You need to configure a wildcard DNS for both the apps domain and system domain. The two domains can be the same, although this is not recommended.' Below this, there are two input fields: 'System Domain *' with the value 'sys.example.com' and 'Apps Domain *' with the value 'apps.example.com'. A blue 'Save' button is at the bottom left.

2. Enter the system and application domains.

- The **System Domain** defines your target when you push apps to PAS.
- The **Apps Domain** defines where PAS should serve your apps.

 **Note:** Pivotal recommends that you use the same domain name but different subdomain names for your system and app domains. Doing so allows you to use a single wildcard certificate for the domain while preventing apps from creating routes that overlap with system routes. For example, name your system domain `system.EXAMPLE.com` and your apps domain `apps.EXAMPLE.com`.

 **Note:** You configured wildcard DNS records for these domains in an earlier step.

3. Click **Save**.

Step 4: Configure Networking

1. Select **Networking**.

2. The values you enter in the **Router IPs** and **HAProxy IPs** fields depend on whether you are using HAProxy in your deployment. Use the table below to determine how to complete these fields.

 **Note:** If you choose to assign specific IP addresses in either the **Router IPs** or **HAProxy IPs** field, ensure that these IP addresses are in the subnet that you configured for PAS in Ops Manager.

| Using HAProxy? | Router IPs Field | HAProxy IPs Field |
|----------------|--|--|
| No | <ol style="list-style-type: none"> 1. Choose IP addresses from the subnet you configured in Ops Manager. 2. Enter these IP addresses in the Router IPs field. You should specify more than one IP address for high availability. 3. Configure your load balancer to forward requests for the domains that you have configured for your deployment to these IP addresses. | Leave this field blank. |
| Yes | Leave this field blank. | <ol style="list-style-type: none"> 1. Choose IP addresses from the subnet you configured in Ops Manager. 2. Enter these IP addresses in the HAProxy IPs field. You should specify more than one IP address for high availability. 3. Configure your load balancer to forward requests for the domains you have configured for your deployment to these IP addresses. |

3. (Optional) In **SSH Proxy IPs**, add the IP address for your Diego Brain, which will accept requests to SSH into application containers on port `2222`.

4. (Optional) In **TCP Router IPs**, add the IP address(es) you would like assigned to the TCP Routers. You enable this feature at the bottom of this screen.

Configure security and routing services for your platform. It is usually preferable to use your own load balancer instead of an HAProxy instance as your point-of-entry to the platform.

Router IPs

10.85.10.200

SSH Proxy IPs

10.85.10.201

HAProxy IPs

TCP Router IPs

5. Under **Certificates and Private Key for HAProxy and Router**, you must provide at least one **Certificate and Private Key** name and certificate keypair for HAProxy and Gorouter. The HAProxy and Gorouter are enabled to receive TLS communication by default. You can configure multiple certificates for HAProxy and Gorouter.

- a. Click the **Add** button to add a name for the certificate chain and its private keypair. This certificate is the default used by Gorouter and HAProxy.

Certificates and Private Keys for HAProxy and Router

Add

▼ example-cert

Name *

example-cert

A human-readable name describing the use of this certificate.

Certificate and Private Key for HAProxy and Router *

-----BEGIN CERTIFICATE-----

-----END RSA PRIVATE KEY-----

Generate RSA Certificate

▼ example-cert-2

Name *

example-cert-2

Certificate and Private Key for HAProxy and Router *

-----BEGIN CERTIFICATE-----

MIIE...

-----END CERTIFICATE-----

-----BEGIN RSA PRIVATE KEY-----

MIIE...

-----END RSA PRIVATE KEY-----

You can either provide a certificate signed by a Certificate Authority (CA) or click on the **Generate RSA Certificate** link to generate a self-signed certificate in Ops Manager.

- b. If you want to configure multiple certificates for HAProxy and Gorouter, click the **Add** button and fill in the appropriate fields for each additional certificate keypair.

For details about generating certificates in Ops Manager for your wildcard system domains, see the [Providing a Certificate for Your SSL/TLS Termination Point](#) topic.

Note: If you configured Ops Manager Front End without a certificate, you can use this new certificate to complete Ops Manager configuration. To configure your Ops Manager Front End certificate, see *Configure Front End* in [Preparing to Deploy Ops Manager on GCP Manually](#).

Note: Ensure that you add any certificates that you generate in this pane to your infrastructure load balancer.

- (Optional) When validating client requests using mutual TLS, the Gorouter trusts multiple certificate authorities (CAs) by default. If you want to configure the Gorouter and HAProxy to trust additional CAs, enter your CA certificates under **Certificate Authorities Trusted by Router and HAProxy**. All CA certificates should be appended together into a single collection of PEM-encoded entries.

Certificate Authorities Trusted by Router and HAProxy

In addition to well-known, public CAs, and those trusted via the BOSH trusted certificates collection, these certificates can be used to validate the certificates from incoming client requests. All CA certificates should be appended together into a single collection of PEM-encoded entries.

- In the **Minimum version of TLS supported by HAProxy and Routerfield**, select the minimum version of TLS to use in HAProxy and Gorouter communications. HAProxy and Gorouter use TLS v1.2 by default. If you need to accommodate clients that use an older version of TLS, select a lower minimum version. For a list of TLS ciphers supported by the Gorouter, see [Securing Traffic into Cloud Foundry](#).

Minimum version of TLS supported by HAProxy and Router*

☐ TLSv1.0

☐ TLSv1.1

☒ TLSv1.2

- Configure **Logging of Client IPs in CF Router**. The **Log client IPs** option is set by default. To comply with the General Data Protection Regulation (GDPR), select one of the following options to disable logging of client IP addresses:

- If your load balancer exposes its own source IP address, disable logging of the `X-Forwarded-For` HTTP header only.
- If your load balancer exposes the source IP of the originating client, disable logging of both the source IP address and the `X-Forwarded-For` HTTP header.

Logging of Client IPs in CF Router*

☒ Log client IPs

☐ Disable logging of X-Forwarded-For header only

☐ Disable logging of both source IP and X-Forwarded-For header

To comply with GDPR, select one of the options to disable logging of client IPs. If the source IP exposed by your load balancer is its own, choose to disable logging of XFF header only. If the source IP exposed by your load balancer is that of the downstream client, choose to disable logging of the source IP also.

- Under **Configure support for the X-Forwarded-Client-Cert header**, configure PCF handles `x-forwarded-client-cert` (XFCC) HTTP headers based on where TLS is terminated for the first time in your deployment.

Configure support for the X-Forwarded-Client-Cert header. This header can be used by applications to verify the requester via mutual TLS. The option you should select depends upon where you will be terminating the TLS connection for the first time. *

☒ TLS terminated for the first time at infrastructure load balancer

☐ TLS terminated for the first time at HAProxy

☐ TLS terminated for the first time at the Router

The following table

indicates which option to choose based on your deployment layout.

| If your deployment is configured as follows: | Then select the following option: | Additional notes: |
|--|--|--|
| <ul style="list-style-type: none"> The Load Balancer is terminating TLS, and Load balancer is configured to put the client certificate from a mutual authentication TLS handshake into the X-Forwarded-Client-Cert HTTP header | TLS terminated for the first time at infrastructure load balancer (default). | Both HAProxy and the Gorouter forward the XFCC header when included in the request. |
| <ul style="list-style-type: none"> The Load Balancer is configured to pass through the TLS handshake via TCP to the instances of HAProxy, and HAProxy instance count is > 0 | TLS terminated for the first time at HAProxy. | <p>HAProxy sets the XFCC header with the client certificate received in the TLS handshake. The Gorouter forwards the header.</p> <p> Breaking Change: In the Router behavior for Client Certificates field, you cannot select the Router does not request client certificates option.</p> |
| <ul style="list-style-type: none"> The Load Balancer is configured to pass through the TLS handshake via TCP to instances of the Gorouter | TLS terminated for the first time at the Gorouter. | <p>The Gorouter strips the XFCC header if it is included in the request and forwards the client certificate received in the TLS handshake in a new XFCC header.</p> <p>If you have deployed instances of HAProxy, app traffic bypasses those instances in this configuration. If you have also configured your load balancer to route requests for ssh directly to the Diego Brain, consider reducing HAProxy instances to 0.</p> <p> Breaking Change: In the Router behavior for Client Certificates field, you cannot select the Router does not request client certificates option.</p> |

For a description of the behavior of each configuration option, see [Forward Client Certificate to Applications](#).

10. To configure HAProxy to handle client certificates, select one of the following options in the **HAProxy behavior for Client Certificate Validation** field.

HAProxy behavior for Client Certificate Validation*

☒ HAProxy does not request client certificates.

☐ HAProxy requests but does not require client certificates. This option is necessary if you want to enable mTLS for applications and TLS is terminated for the first time at HAProxy

- HAProxy does not request client certificates.** This option requires mutual authentication, which makes it incompatible with XFCC option **TLS terminated for the first time at HAProxy**. HAProxy does not request client certificates, so the client does not provide them and no validation occurs. This is the default configuration.
- HAProxy requests but does not require client certificates.** The HAProxy requests client certificates in TLS handshakes, validates them when presented, but does not require them.

 **warning:** Upon upgrade, PAS will fail to receive requests if your load balancer is configured to present a client certificate in the TLS handshake with HAProxy but HAProxy has not been configured with the certificate authority used to sign it. To mitigate this issue, select **HAProxy does not request client certificates** in the **Networking** pane or configure the HAProxy with the appropriate CA.

11. To configure Gorouter behavior for handling client certificates, select one of the following options in the **Router behavior for Client Certificate Validation** field.

Router behavior for Client Certificate Validation*

- ☐ Router does not request client certificates. This option is incompatible with XFCC options "TLS terminated for the first time at HAProxy" and "TLS terminated for the first time at the Router" because these options require mutual authentication.
- ☒ Router requests but does not require client certificates.
- ☐ Router requires client certificates.

- o **Router does not request client certificates.** This option is incompatible with the XFCC configuration options **TLS terminated for the first time at HAProxy** and **TLS terminated for the first time at the Router** in PAS because these options require mutual authentication. As client certificates are not requested, client will not provide them, and thus validation of client certificates will not occur.
- o **Router requests but does not require client certificates.** The Gorouter requests client certificates in TLS handshakes, validates them when presented, but does not require them. This is the default configuration.
- o **Router requires client certificates.** The Gorouter validates that the client certificate is signed by a Certificate Authority that the Gorouter trusts. If the Gorouter cannot validate the client certificate, the TLS handshake fails.

⚠ warning: Requests to the platform will fail upon upgrade if your load balancer is configured with client certificates and the Gorouter does not have the certificate authority. To mitigate this issue, select **Router does not request client certificates** for **Router behavior for Client Certificate Validation** in the **Networking** pane.

12. In the **TLS Cipher Suites for Router** field, review the TLS cipher suites for TLS handshakes between Gorouter and front-end clients such as load balancers or HAProxy. The default value for this field is `ECDHE-RSA-AES128-GCM-SHA256:TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384`. If you want to modify the default configuration, use an ordered, colon-delimited list of Golang-supported TLS cipher suites in the OpenSSL format. Operators should verify that the ciphers are supported by any clients or front-end components that will initiate TLS handshakes with Gorouter. For a list of TLS ciphers supported by Gorouter, see [Securing Traffic into Cloud Foundry](#).

TLS Cipher Suites for Router *

`ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384`

Verify that every client participating in TLS handshakes with Gorouter has at least one cipher suite in common with Gorouter.

💡 Note: Specify cipher suites that are supported by the versions configured in the **Minimum version of TLS supported by HAProxy and Router** field.

13. In the **TLS Cipher Suites for HAProxy** field, review the TLS cipher suites for TLS handshakes between HAProxy and its clients such as load balancers and Gorouter. The default value for this field is the following:
`DHE-RSA-AES128-GCM-SHA256:DHE-RSA-AES256-GCM-SHA384:ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384` If you want to modify the default configuration, use an ordered, colon-delimited list of TLS cipher suites in the OpenSSL format. Operators should verify that the ciphers are supported by any clients or front-end components that will initiate TLS handshakes with HAProxy.

TLS Cipher Suites for HAProxy *

`DHE-RSA-AES128-GCM-SHA256:DHE-RSA-AES256-GCM-SHA384:ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384`

Verify that every client participating in TLS handshakes with HAProxy has at least one cipher suite in common with HAProxy.

 **Note:** Specify cipher suites that are supported by the versions configured in the **Minimum version of TLS supported by HAProxy and Router** field.

14. Under **HAProxy forwards requests to Router over TLS**, select **Enable** or **Disable** based on your deployment layout.

HAProxy forwards requests to Router over TLS. When enabled, HAProxy will forward all requests to the Router over TLS. HAProxy will use the CA provided to verify the certificates provided by the Router. *

☒ **Enable**

Certificate Authority for HAProxy Backend *

You need to provide a certificate authority for the certificate and key provided in the "Certificate and Private Key for HAProxy and Router" field. HAProxy will verify those certificates using this CA when establishing a connection. If you generated that certificate and key using the "Generate RSA Certificate" feature, then your CA is the Ops Manager CA, and can be found by visiting the "/api/v0/certificate_authorities" API endpoint.

☐ **Disable**

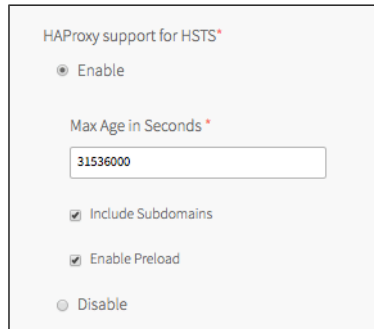

- **Enable HAProxy forwarding of requests to Router over TLS**

| | |
|--------------------------------------|---|
| If you want to: | Encrypt communication between HAProxy and the Gorouter |
| Then configure the following: | <ol style="list-style-type: none"> 1. Leave Enable selected. 2. In the Certificate Authority for HAProxy Backend field, specify the Certificate Authority (CA) that signed the certificate you configured in the Certificate and Private Key for HAProxy and Router field. <div>  Note: If you used the Generate RSA Certificate link to generate a self-signed certificate, then the CA to specify is the Ops Manager CA, which you can locate at the <code>/api/v0/certificate_authorities</code> endpoint in the Ops Manager API. </div> <ol style="list-style-type: none"> 3. Make sure that Gorouter and HAProxy have TLS cipher suites in common in the TLS Cipher Suites for Router and TLS Cipher Suites for HAProxy fields. |
| See also: | <ul style="list-style-type: none"> ◦ Terminating SSL/TLS at the Load Balancer and Gorouter ◦ Providing a Certificate for Your SSL/TLS Termination Point ◦ Using the Ops Manager API |

- **Disable HAProxy forwarding of requests to Router over TLS**

| | |
|--------------------------------------|---|
| If you want to: | Use non-encrypted communication between HAProxy and Gorouter, or you are not using HAProxy |
| Then configure the following: | <ol style="list-style-type: none"> 1. Select Disable. 2. If you are not using HAProxy, set the number of HAProxy job instances to <code>0</code> on the Resource Config page. See Disable Unused Resources. |
| See also: | <ul style="list-style-type: none"> ◦ Terminating SSL/TLS at the Gorouter Only ◦ Terminating SSL/TLS at the Load Balancer Only |

15. If you want to force browsers to use HTTPS when making requests to HAProxy, select **Enable** in the **HAProxy support for HSTS** field and complete

HAProxy support for HSTS*

☒ Enable

Max Age in Seconds*

31536000

☒ Include Subdomains

☒ Enable Preload

☐ Disable

the following optional configuration steps:

- (Optional) Enter a **Max Age in Seconds** for the HSTS request. By default, the age is set to one year. HAProxy will force HTTPS requests from browsers for the duration of this setting.
- (Optional) Select the **Include Subdomains** checkbox to force browsers to use HTTPS requests for all component subdomains.
- (Optional) Select the **Enable Preload** checkbox to force instances of Google Chrome, Firefox, and Safari that access your HAProxy to refer to their built-in lists of known hosts that require HTTPS, of which HAProxy is one. This ensures that the first contact a browser has with your HAProxy is an HTTPS request, even if the browser has not yet received an HSTS header from HAProxy.

- If you are not using SSL encryption or if you are using self-signed certificates, select **Disable SSL certificate verification for this environment**. Selecting this checkbox also disables SSL verification for route services.

 **Note:** For production deployments, Pivotal does not recommend disabling SSL certificate verification.

- (Optional) If you want HAProxy or the Gorouter to reject any HTTP (non-encrypted) traffic, select the **Disable HTTP on HAProxy and Gorouter** checkbox. When selected, HAProxy and Gorouter will not listen on port 80.

☐ Disable HTTP on HAProxy and Gorouter

- (Optional) Select the **Disable insecure cookies on the Router** checkbox to set the secure flag for cookies generated by the router.
- (Optional) To disable the addition of Zipkin tracing headers on the Gorouter, deselect the **Enable Zipkin tracing headers on the router** checkbox. Zipkin tracing headers are enabled by default. For more information about using Zipkin trace logging headers, see [Zipkin Tracing in HTTP Headers](#).
- (Optional) To stop the Router from writing access logs to local disk, deselect the **Enable Router to write access logs locally** checkbox. You should consider disabling this checkbox for high traffic deployments since logs may not be rotated fast enough and can fill up the disk.
- By default, the PAS routers handle traffic for applications deployed to an isolation segment created by the PCF Isolation Segment tile. To configure the PAS routers to reject requests for applications within isolation segments, select the **Routers reject requests for Isolation Segments** checkbox.

☐ Routers reject requests for Isolation Segments

Do not enable this option without deploying

routers for each isolation segment. See the following topics for more information:

- [Installing PCF Isolation Segment](#)
- [Sharding Routers for Isolation Segments](#)

- (Optional) By default, Gorouter support for the PROXY protocol is disabled. To enable the PROXY protocol, select **Enable support for PROXY protocol in CF Router**. When enabled, client-side load balancers that terminate TLS but do not support HTTP can pass along information from the originating client. Enabling this option may impact Gorouter performance. For more information about enabling the PROXY protocol in Gorouter, see the *HTTP Header Forwarding* sections in the [Securing Traffic in Cloud Foundry](#) topic.
- In the **Choose whether to enable route services** section, choose either **Enable route services** or **Disable route services**. Route services are a class of [marketplace services](#) that perform filtering or content transformation on application requests and responses. See the [Route Services](#) topic for details.
 - If you enabled route services, you can also configure the **Bypass security checks for route service lookup** field. Pivotal recommends that you do not enable this field because it has potential security concerns. However, you may need to enable it if your load balancer requires mutual TLS from clients. For more information, see [Configuring Route Service Lookup](#).
- (Optional) If you want to limit the number of app connections to the backend, enter a value in the **Max Connections Per Backend** field. You can use this field to prevent a poorly behaving app from all the connections and impacting other apps.

To choose a value for this field, review the peak concurrent connections received by instances of the most popular apps in your deployment. You can determine the number of concurrent connections for an app from the `httpStartStop` event metrics emitted for each app request.

If your deployment uses PCF Metrics, you can also obtain this peak concurrent connection information from [Network Metrics](#). The default value is

Max Connections Per Backend *

0

500

25. Under **Enable Keepalive Connections for Router**, select **Enable** or **Disable**. Keepalive connections are enabled by default. For more information, see [Keepalive Connections](#) in *HTTP Routing*.

Enable Keepalive Connections for Router*

☒ Enable
 ☐ Disable

26. (Optional) To accommodate larger uploads over connections with high latency, increase the number of seconds in the **Router Timeout to Backends** field.
27. (Optional) Use the **Frontend Idle Timeout for Gorouter and HAProxy** field to help prevent connections from your load balancer to Gorouter or HAProxy from being closed prematurely. The value you enter sets the duration, in seconds, that Gorouter or HAProxy maintains an idle open connection from a load balancer that supports keep-alive.

In general, set the value higher than your load balancer's backend idle timeout to avoid the race condition where the load balancer sends a request before it discovers that Gorouter or HAProxy has closed the connection.

See the following table for specific guidance and exceptions to this rule:

| IaaS | Guidance |
|-------|---|
| AWS | AWS ELB has a default timeout of 60 seconds, so Pivotal recommends a value greater than <code>60</code> . |
| Azure | By default, Azure load balancer times out at 240 seconds without sending a TCP RST to clients, so as an exception, Pivotal recommends a value lower than <code>240</code> to force the load balancer to send the TCP RST. |
| GCP | GCP has a default timeout of 600 seconds. For GCP HTTP load balancers, Pivotal recommends a value greater than <code>600</code> . For GCP TCP load balancers, Pivotal recommends a value less than <code>600</code> to force the load balancer to send a TCP RST. |
| Other | Set the timeout value to be greater than that of the load balancer's backend idle timeout. |

 **Note:** Do not set a frontend idle timeout lower than six seconds.

28. (Optional) Increase the value of **Load Balancer Unhealthy Threshold** to specify the amount of time, in seconds, that the router continues to accept connections before shutting down. During this period, healthchecks may report the router as unhealthy, which causes load balancers to failover to other routers. Set this value to an amount greater than or equal to the maximum time it takes your load balancer to consider a router instance unhealthy, given contiguous failed healthchecks.
29. (Optional) Modify the value of **Load Balancer Healthy Threshold**. This field specifies the amount of time, in seconds, to wait until declaring the Router instance started. This allows an external load balancer time to register the Router instance as healthy.

Load Balancer Unhealthy Threshold *

20

Load Balancer Healthy Threshold *

20

30. (Optional) If app developers in your organization want certain HTTP headers to appear in their app logs with information from the Gorouter, specify them in the **HTTP Headers to Log** field. For example, to support app developers that deploy Spring apps to PCF, you can enter [Spring-specific HTTP headers](#).

HTTP Headers to Log

31. If you expect requests larger than the default maximum of 16 Kbytes, enter a new value (in bytes) for **HAProxy Request Max Buffer Size**. You may need to do this, for example, to support apps that embed a large cookie or query string values in headers.

32. If your PCF deployment uses HAProxy and you want it to receive traffic only from specific sources, use the following fields:

- **HAProxy Protected Domains:** Enter a comma-separated list of domains to protect from unknown source requests.
- **HAProxy Trusted CIDRs:** Optionally, enter a space-separated list of CIDRs to limit which IP addresses from the **Protected Domains** can send traffic to PCF.

HAProxy Protected Domains

A comma-separated list of domains to protect from requests from unknown sources. Use this property in conjunction with "Trusted CIDRs" to protect these domains from requests from unknown sources.

HAProxy Trusted CIDRs

33. The **Loggregator Port** defaults to **443** if left blank. Enter a new value to override the default.

Container Network Interface Plugin*

34. For **Container Network Interface Plugin**, ensure **Silk** is selected and review the following fields:

Note: The **External** option exists to support NSX-T integration for vSphere deployments.

- (Optional) You can change the value in the **Applications Network Maximum Transmission Unit (MTU)** field. Pivotal recommends setting the MTU value for your application network to **1454**. Some configurations, such as networks that use GRE tunnels, may require a smaller MTU value.
- (Optional) Enter an IP range for the overlay network in the **Overlay Subnet** box. If you do not set a custom range, Ops Manager uses **10.255.0.0/16**.

Warning: The overlay network IP range must not conflict with any other IP addresses in your network.

- Enter a UDP port number in the **VXLAN Tunnel Endpoint Port** box. If you do not set a custom port, Ops Manager uses 4789.
- For **Denied logging interval**, set the per-second rate limit for packets blocked by either a container-specific [networking policy](#) or by [Application Security Group](#) rules applied across the space, org, or deployment. This field defaults to **1**.
- For **UDP logging interval**, set the per-second rate limit for UDP packets sent and received. This field defaults to **100**.
- To enable logging for app traffic, select **Log traffic for all accepted/denied application packets**. See [Manage Logging for Container-to-Container Networking](#) for more information.
- By default, containers use the same DNS servers as the host. If you want to override the DNS servers to be used in containers, enter a comma-separated list of servers in **DNS Servers**.

Note: If your deployment uses BOSH DNS, which is the default, you cannot use this field to override the DNS servers used in containers.

35. For **DNS Search Domains**, enter DNS search domains for your containers as a comma-separated list. DNS on your containers appends these names to its host names, to resolve them into full domain names.

36. For **Database Connection Timeout**, set the connection timeout for clients of the policy server and silk databases. The default value is **120**. You may need to increase this value if your deployment experiences timeout issues related to Container-to-Container Networking.

DNS Search Domains

example.com, myapps.com

DNS search domains to be used in containers. A comma-separated list can be specified.

37. (Optional) TCP Routing is disabled by default. You should enable this feature if your DNS sends TCP traffic through a load balancer rather than directly to a TCP router. To enable TCP routing:

- a. Select **Enable TCP Routing**.
- b. For **TCP Routing Ports**, enter a single port or a range of ports for the load balancer to forward to. These are the same ports that you configured in the [Pre-Deployment Steps](#) of the *Enabling TCP Routing* topic.
 - To support multiple TCP routes, Pivotal recommends allocating multiple ports.
 - To allocate a list of ports rather than a range:
 1. Enter a single port in the **TCP Routing Ports** field.
 2. After deploying PAS, follow the directions in [Configuring a List of TCP Routing Ports](#) to add TCP routing ports using the cf CLI.

Enable TCP requests to your apps via specific ports on the TCP router. You will want to configure a load balancer to forward these TCP requests to the TCP routers. If you do not have a load balancer, then you can also send traffic directly to the TCP router.*

☐ Select this option if you prefer to enable TCP Routing at a later time
 ☒ Enable TCP Routing

TCP Routing Ports (one-time configuration, if you want to update this value you can via the CF CLI) *

- c. Return to the top of the **Networking** screen. In **TCP Router IPs** field, make sure you have entered IP addresses within your subnet CIDR block. These will be the same IP addresses you configured your load balancer with in [Pre-Deployment Steps](#), unless you configured DNS to resolve the TCP domain name directly to an IP you've chosen for the TCP router. You can enter multiple values as a comma-delimited list or as a range. For example, `10.254.0.1, 10.254.0.2` or `10.254.0.1-10.254.0.2`.
- d. (Optional) To disable TCP routing, click **Select this option if you prefer to enable TCP Routing at a later time** For more information, see the [Configuring TCP Routing in PAS](#) [↗](#) topic.

38. Click **Save**.

Step 5: Configure Application Containers

1. Select **Application Containers**.

Enable microservice frameworks, private Docker registries, and other services that support your applications at a container level.

- ☒ Enable Custom Buildpacks
- ☒ Allow SSH access to app containers
- ☒ Enable SSH when an app is created
- ☒ Enable the GrootFS container image plugin for Garden RunC

☐ Router uses TLS to verify application identity

Private Docker Insecure Registry Whitelist

10.10.10.10:8888,example.com:8888

Docker Images Disk-Cleanup Scheduling on Cell VMs*

- ☐ Never clean up Cell disk-space
- ☐ Routinely clean up Cell disk-space
- ☒ Clean up disk-space once threshold is reached

Threshold of Disk-Used (MB) (min: 1) *

10240

- The **Enable Custom Buildpacks** checkbox governs the ability to pass a custom buildpack URL to the `-b` option of the `cf push` command. By default, this ability is enabled, letting developers use custom buildpacks when deploying apps. Disable this option by disabling the checkbox. For more information about custom buildpacks, refer to the [buildpacks](#) section of the PCF documentation.
- The **Allow SSH access to app containers** checkbox controls SSH access to application instances. Enable the checkbox to permit SSH access across your deployment, and disable it to prevent all SSH access. See the [Application SSH Overview](#) topic for information about SSH access permissions at the space and app scope.
- If you want to enable SSH access for new apps by default in spaces that allow SSH, select **Enable SSH when an app is created**. If you deselect the checkbox, developers can still enable SSH after pushing their apps by running `cf enable-ssh APP-NAME`.
- If you want to disable the Garden Root filesystem (GrootFS), deselect the **Enable the GrootFS container image plugin for Garden RunC** checkbox. Pivotal recommends using this plugin, so it is enabled by default. However, some external components are sensitive to dependencies with filesystems such as GrootFS. If you experience issues, such as antivirus or firewall compatibility problems, deselect the checkbox to roll back to the plugin that is built into Garden RunC. For more information about GrootFS, see [Component: Garden](#) and [Container Mechanics](#).

 **Note:** If you modify this setting, Pivotal recommends recreating all VMs in the BOSH Director config. You can do this by selecting the **Recreate all VMs** checkbox in the **Director Config** pane of the BOSH Director tile before you redeploy.

- To enable Gorouter to verify app identity using TLS, select the **Router uses TLS to verify application identity** checkbox.

Verifying app identity using TLS enables encryption between router and app containers and guards against misrouting during control plane failures. For more information about Gorouter route consistency modes, see [Preventing Misrouting](#) in *HTTP Routing*.

 **warning:** TLS routing requires an additional 32 MB of RAM capacity on Diego cells per app instance. It also requires additional CPU capacity on Diego cells. If the total amount of Diego cell memory available is less than 32 MB times the number of running app instances, scale your Diego cells before configuring the Gorouter with TLS.

 **Warning:** You may see an increase of memory and CPU usage for your Gorouters after enabling TLS routing. If the total amount of memory and CPU usage of the Gorouters in your environment are close to the size limit, scale your Gorouters before enabling TLS routing.

7. You can configure Pivotal Application Service (PAS) to run app instances in Docker containers by supplying their IP address ranges in the **Private Docker Insecure Registry Whitelist** textbox. See the [Using Docker Registries](#) topic for more information.
8. Select your preference for **Docker Images Disk-Cleanup Scheduling on Cell VMs**. If you choose **Clean up disk-space once threshold is reached**, enter a **Threshold of Disk-Used** in megabytes. For more information about the configuration options and how to configure a threshold, see [Configuring Docker Images Disk-Cleanup Scheduling](#).
9. Enter a number in the **Max Inflight Container Starts** textbox. This number configures the maximum number of started instances across the Diego cells in your deployment. For more information about this feature, see [Setting a Maximum Number of Started Containers](#).
10. Under **Enabling NFSv3 volume services**, select **Enable** or **Disable**. NFS volume services allow application developers to bind existing NFS volumes to their applications for shared file access. For more information, see the [Enabling NFS Volume Services](#) topic.

 **Note:** In a clean install, NFSv3 volume services is enabled by default. In an upgrade, NFSv3 volume services is set to the same setting as it was in the previous deployment.

11. (Optional) To configure LDAP for NFSv3 volume services, do the following:

Enabling NFSv3 volume services will allow application developers to bind existing NFS volumes to their applications for shared file access. *

☒ Enable

LDAP Service Account User

LDAP Service Account Password

LDAP Server Host

LDAP Server Port

LDAP User Fully-Qualified Domain Name

☐ Disable

Format of timestamps in Diego logs*

☒ RFC3339 timestamps (e.g. 2018-02-09T00:54:13.479724884Z)

☐ Seconds since the Unix epoch (e.g. 1518137653.479724884)

Save

- For **LDAP Service Account User**, enter the username of the service account in LDAP that will manage volume services.
- For **LDAP Service Account Password**, enter the password for the service account.
- For **LDAP Server Host**, enter the hostname or IP address of the LDAP server.
- For **LDAP Server Port**, enter the LDAP server port number. If you do not specify a port number, Ops Manager uses 389.
- For **LDAP User Fully-Qualified Domain Name**, enter the fully qualified path to the LDAP service account. For example, if you have a service account named `volume-services` that belongs to organizational units (OU) named `service-accounts` and `my-company`, and your domain is named `domain`, the fully qualified path looks like the following:

```
CN=volume-services,OU=service-accounts,OU=my-company,DC=domain,DC=com
```

12. By default, PAS manages container images using the [GrootFS](#) plugin for Garden-runC. If you experience issues with GrootFS, you can disable the plugin and use the image plugin built into Garden-runC.

13. Select the **Format of timestamps in Diego logs**, either **RFC3339 timestamps** or **Seconds since the Unix epoch**. Fresh PAS v2.2 installations default to **RFC3339 timestamps**, while upgrades to PAS v2.2 from previous versions default to **Seconds since the Unix epoch**.
14. You can optionally modify the **Default health check timeout**. The value configured for this field is the amount of time allowed to elapse between starting up an app and the first healthy response from the app. If the health check does not receive a healthy response within the configured timeout, then the app is declared unhealthy. The default timeout is seconds and the maximum configurable timeout is seconds.
15. Click **Save**.

Step 6: Configure Application Developer Controls

1. Select **Application Developer Controls**.

Configure restrictions and default settings for applications pushed to Application Service.

Maximum File Upload Size (MB) (min: 1024, max: 2048) *

Default App Memory (MB) (min: 64, max: 2048) *

Default App Memory Quota per Org (MB) (min: 10240, max: 102400) *

Maximum Disk Quota per App (MB) (min: 512, max: 20480) *

Default Disk Quota per App (MB) (min: 512, max: 20480) *

Default Service Instances Quota per Org (min: 0, max: 1000) *

Staging Timeout (Seconds) *

☐ Allow Space Developers to manage network policies

☒ Enable Service Discovery for Apps

Save

2. Enter the **Maximum File Upload Size (MB)**. This is the maximum size of an application upload.
3. Enter the **Default App Memory (MB)**. This is the amount of RAM allocated by default to a newly pushed application if no value is specified with the cf CLI.
4. Enter the **Default App Memory Quota per Org**. This is the default memory limit for all applications in an org. The specified limit only applies to the first installation of PAS. After the initial installation, operators can use the cf CLI to change the default value.

5. Enter the **Maximum Disk Quota per App (MB)**. This is the maximum amount of disk allowed per application.

Note: If you allow developers to push large applications, PAS may have trouble placing them on Cells. Additionally, in the event of a system upgrade or an outage that causes a rolling deploy, larger applications may not successfully re-deploy if there is insufficient disk capacity. Monitor your deployment to ensure your Cells have sufficient disk to run your applications.

6. Enter the **Default Disk Quota per App (MB)**. This is the amount of disk allocated by default to a newly pushed application if no value is specified with the cf CLI.
7. Enter the **Default Service Instances Quota per Org**. The specified limit only applies to the first installation of PAS. After the initial installation, operators can use the cf CLI to change the default value .
8. Enter the **Staging Timeout (Seconds)**. When you stage an application droplet with the Cloud Controller, the server times out after the number of seconds you specify in this field.
9. Select the **Allow Space Developers to manage network policies** checkbox to permit developers to manage their own network policies for their applications.
10. The **Enable Service Discovery for Apps** checkbox, which enables service discovery between applications, is enabled by default. To disable this feature, clear this checkbox. For more information about application service discovery, see the [App Service Discovery](#) section of the *Understanding Container-to-Container Networking* topic.
11. Click **Save**.

Step 7: Review Application Security Groups

Setting appropriate [Application Security Groups](#) is critical for a secure deployment. Type ☐ in the box to acknowledge that once the Pivotal Application Service (PAS) deployment completes, you will review and set the appropriate application security groups. See [Restricting App Access to Internal PCF Components](#) for instructions.

Setting appropriate Application Security Groups that control application network policy is the responsibility of the Elastic Runtime administration team. Please refer to the Application Security Groups topic in the Pivotal Cloud Foundry documentation for more detail on completing this activity after the Elastic Runtime deployment completes.

Type X to acknowledge that you understand this message *

Save

Step 8: Configure UAA

1. Select **UAA**.
2. (Optional) Under **JWT Issuer URI**, enter the URI that UAA uses as the issuer when generating tokens.

JWT Issuer URI

3. Under **SAML Service Provider Credentials**, enter a certificate and private key to be used by UAA as a SAML Service Provider for signing outgoing SAML authentication requests. You can provide an existing certificate and private key from your trusted Certificate Authority or generate a self-signed certificate. The following domain must be associated with the certificate: `*.login.YOUR-SYSTEM-DOMAIN`.

Note: The Pivotal Single Sign-On Service and Pivotal Spring Cloud Services tiles require the `*.login.YOUR-SYSTEM-DOMAIN`.

- If the private key specified under **Service Provider Credentials** is password-protected, enter the password under **SAML Service Provider Key**

SAML Service Provider Credentials *

-----BEGIN CERTIFICATE-----
M
U
H
M
-----END CERTIFICATE-----

[Change](#)

SAML Service Provider Key Password

Secret

Password.

- (Optional) To override the default value, enter a custom SAML Entity ID in the **SAML Entity ID Override** field. By default, the SAML Entity ID is `http://login.YOUR-SYSTEM-DOMAIN` where `YOUR-SYSTEM-DOMAIN` is set in the **Domains > System Domain** field.
- For **Signature Algorithm**, choose an algorithm from the dropdown menu to use for signed requests and assertions. The default value is `SHA256`.
- (Optional) In the **Apps Manager Access Token Lifetime**, **Apps Manager Refresh Token Lifetime**, **Cloud Foundry CLI Access Token Lifetime**, and **Cloud Foundry CLI Refresh Token Lifetime** fields, change the lifetimes of tokens granted for Apps Manager and Cloud Foundry Command Line Interface (cf CLI) login access and refresh. Most deployments use the defaults.

Apps Manager Access Token Lifetime (in seconds) *

Apps Manager Refresh Token Lifetime (in seconds) *

Cloud Foundry CLI Access Token Lifetime (in seconds) *

Cloud Foundry CLI Refresh Token Lifetime (in seconds) *

Global Login Session Max Timeout (in seconds) *

Global Login Session Idle Timeout (in seconds) *

Customize Username Label (on login page) *

Customize Password Label (on login page) *

Proxy IPs Regular Expression *

8. (Optional) In the **Global Login Session Max Timeout** and **Global Login Session Idle Timeout** fields, change the maximum number of seconds before a global login times out. These fields apply to the following:
 - **Default zone sessions:** Sessions in Apps Manager, PCF Metrics, and other web UIs that use the UAA default zones
 - **Identity zone sessions:** Sessions in apps that use a UAA identity zone, such as a Single Sign-On service plan
9. (Optional) Customize the text prompts used for username and password from the cf CLI and Apps Manager login popup by entering values for **Customize Username Label (on login page)** and **Customize Password Label (on login page)**.
10. (Optional) The **Proxy IPs Regular Expression** field contains a pipe-delimited set of regular expressions that UAA considers to be reverse proxy IP addresses. UAA respects the `x-forwarded-for` and `x-forwarded-proto` headers coming from IP addresses that match these regular expressions. To configure UAA to respond properly to Gorouter or HAProxy requests coming from a public IP address, append a regular expression or regular expressions to match the public IP address.
11. You can configure UAA to use an internal MySQL database provided with PCF, or you can configure an external database provider. Follow the procedures in either the [Internal Database Configuration](#) or the [External Database Configuration](#) section below.

 **Note:** If you are performing an upgrade, do not modify your existing internal database configuration or you may lose data. You must migrate your existing data before changing the configuration. See [Upgrading Pivotal Cloud Foundry](#) for additional upgrade information, and contact [Pivotal Support](#) for help.

Internal Database Configuration

When you configure the UAA to use an internal MySQL database, it uses the type of database selected in the **Databases** pane. See the [Configure Internal Databases](#) section for details.

1. Select **Internal MySQL**.

Choose the location of your UAA database *

☒ Internal MySQL (preferred for complete high-availability)

☐ External (preferred if, for example, you use AWS RDS)

 **Note:** If you configure your system databases as external in the **Databases** pane, selecting Internal MySQL in the **UAA** pane has no effect.

2. Click **Save**.
3. Ensure that you complete the [Configure Internal MySQL](#) step later in this topic to configure high availability for your internal MySQL databases.

External Database Configuration

1. From the **UAA** section in Pivotal Application Service (PAS), select **External**.

Choose the location of your UAA database *

☐ Internal MySQL (preferred for complete high-availability)

☒ External (preferred if, for example, you use AWS RDS)

Hostname *

TCP Port *

Username *

Password *

2. For **Hostname**, enter the hostname of the database server.
3. For **TCP Port**, enter the port of the database server.
4. For **User Account and Authentication database username**, specify a unique username that can access this specific database on the database server.
5. For **User Account and Authentication database password**, specify a password for the provided username.
6. Click **Save**.

Step 9: Configure CredHub

 **Note:** Enabling CredHub is not required. However, you cannot leave the fields under **Encryption Keys** blank. If you do not intend to use CredHub, enter any text in the **Name** and **Key** fields as placeholder values.

1. Select **CredHub**.
2. Choose the location of your CredHub database. PAS includes this CredHub database for services to store their service instance credentials.

 **Note:** You cannot choose **Internal** for the CredHub database if you choose **External** for your System Databases. See [Configure System](#)

Databases below.

Configure the CredHub Server

Choose the location of your CredHub database *

- ☒ Internal MySQL (preferred for complete high-availability)
- ☐ External (preferred if, for example, you use Google Cloud SQL)

If you chose **External**, enter the following:

- **Hostname.** This is the IP address of your database server.
- **TCP Port.** This is the port of your database server, such as `3306`.
- **Username.** This is a unique username that can access your CredHub database on the database server.
- **Password.** This is the password for the provided username.
- **Database CA Certificate.** This certificate is used when encrypting traffic to and from the database.

3. Under **Encryption Keys**, specify one or more keys to use for encrypting and decrypting the values stored in the CredHub database.

Encryption Keys

Name *

Name of the encryption key.

Provider*

Key *

☐ Primary

- **Name.** This is the name of the encryption key.
 - If you plan to use internal encryption, enter any key name.
 - If you plan to use an HSM as your encryption provider, enter a key name that already exists on your HSM or a new key name. For each new key name, CredHub generates a key in **HSM Provider Partition** that you configure below.
- **Provider.** This is the provider of the encryption key. If you plan to configure an HSM provider and HSM servers below, select **HSM**. Otherwise, select **Internal**.
- **Key.** If you select internal encryption, this key is used for encrypting all data. The key must be at least 20 characters long.
 - If you selected **Internal** above, enter a randomly generated value under **Key**.
 - If you selected **HSM** above, enter a placeholder value under **Key**. CredHub does not use this key for encryption. However, you cannot leave the **Key** field blank.
- **Primary.** This checkbox is used for marking the key you specified above as the primary encryption key. You must mark one key as **Primary**. Do not mark more than one key as **Primary**.

Note: For information about using additional keys for key rotation, see the [Rotating Runtime CredHub Encryption Keys](#) topic.

4. (Optional) To configure CredHub to use an HSM, complete the following fields:

- **HSM Provider Partition.** This is the name of the HSM provider partition.
- **HSM Provider Partition Password.** This password is used to access the HSM provider partition.
- **HSM Provider Client Certificate.** This is the client certificate for the HSM. For more information, see [Create and Register HSM Clients](#) in the

Preparing CredHub HSMs for Configuration topic.

- In the **HSM Provider Servers** section, click **Add** to add an HSM server. You can add multiple HSM servers. For each HSM server, complete the following fields:
 - **Host Address.** This is the host name or IP address of the HSM server.
 - **Port.** This is the port of the HSM server. If you do not know your port address, enter `1792`.
 - **Partition Serial Number.** This is the serial number of the HSM partition.
 - **HSM Certificate.** This is the certificate for the HSM server. The HSM presents this certificate to CredHub to establish a two-way TLS connection.

5. If your deployment uses any PCF services that support storing service instance credentials in CredHub and you want to enable this feature, select the **Secure Service Instance Credentials** checkbox.

6. Click **Save**.

7. Select the **Resource Config** pane.

8. Under the **Job** column of the **CredHub** row, set the number of instances to `2`. This is the minimum instance count required for high availability.

9. Click **Save**.

For more information about using CredHub for securing service instance credentials, see [Securing Service Instance Credentials with Runtime CredHub](#).

Step 10: Configure Authentication and Enterprise SSO

1. Select **Authentication and Enterprise SSO**.

Configure your user store access, which can be an internal user store (managed by Cloud Foundry's UAA) or an external user store (LDAP or SAML). You can also adjust the lifetimes of authentication tokens.

Configure your UAA user account store with either internal or external authentication mechanisms *

☒ Internal UAA (provided by Elastic Runtime; configure your password policy below)

Minimum Password Length *

Minimum Uppercase Characters Required for Password *

Minimum Lowercase Characters Required for Password *

Minimum Numerical Digits Required for Password *

Minimum Special Characters Required for Password *

Maximum Password Entry Attempts Allowed *

2. To authenticate user sign-ons, your deployment can use one of three types of user database: the UAA server's internal user store, an external SAML identity provider, or an external LDAP server.

- To use the internal UAA, select the **Internal** option and follow the instructions in the [Configuring UAA Password Policy](#) topic to configure your password policy.
- To connect to an external identity provider through SAML, scroll down to select the **SAML Identity Provider** option and follow the instructions in the [Configuring PCF for SAML](#) section of the *Configuring Authentication and Enterprise SSO for Pivotal Application Service (PAS)* topic.
- To connect to an external LDAP server, scroll down to select the **LDAP Server** option and follow the instructions in the [Configuring LDAP](#) section of the *Configuring Authentication and Enterprise SSO for PAS* topic.

3. Click **Save**.

Step 11: Configure System Databases

You can configure PAS to use an internal MySQL database provided with PCF, or you can configure an external database provider for the databases required by PAS.

 **Note:** If you are performing an upgrade, do not modify your existing internal database configuration or you may lose data. You must migrate your existing data first before changing the configuration. Contact Pivotal Support for help. See [Upgrading Pivotal Cloud Foundry](#) for additional upgrade information.

Internal Database Configuration

If you want to use internal databases for your deployment, perform the following steps:

1. Select **Databases**.

2. Select one of the **Internal Databases** options:

- **Internal Databases - MySQL - Percona XtraDB Cluster** uses [Percona Server](#) with TLS encryption between server cluster nodes.
- **Internal Databases - MySQL - MariaDB Galera Cluster** uses [MariaDB](#) with cluster nodes communicating over plaintext.

⚠ warning: Changing existing internal databases from **MySQL - MariaDB Galera Cluster** to **MySQL - Percona XtraDB Cluster** migrates the databases after you click **Apply Changes**, causing temporary system downtime. See [Migrate to Internal Percona MySQL](#) for details.

Choose the location of your system databases. Please consult the documentation for migrating existing installations from MariaDB to Percona. *

- ☒ Internal Databases - MySQL - Percona XtraDB Cluster
- ☐ Internal Databases - MySQL - MariaDB Galera Cluster (deprecated - planned to be removed in PAS 2.4)
- ☐ External Databases - (e.g. AWS RDS)

Save

3. Click **Save**.

Then proceed to [Step 12: \(Optional\) Configure Internal MySQL](#) to configure high availability for your internal MySQL databases.

External Database Configuration

⚠ warning: Protect whichever database you use in your deployment with a password.

To create your Pivotal Application Service (PAS) databases, follow the procedure below.

💡 Note: Exact configurations depend on your database provider. The following procedure uses AWS RDS as an example.

1. Add the `ubuntu` account key pair from your IaaS deployment to your local SSH profile so you can access the Ops Manager VM. For example, in AWS, you add a key pair created in AWS:

```
$ ssh-add aws-keypair.pem
```

2. SSH in to your Ops Manager using the Ops Manager FQDN and the username `ubuntu`:

```
$ ssh ubuntu@OPS-MANAGER-FQDN
```

3. Log in to your MySQL database instance using the appropriate hostname and user login values configured in your IaaS account. For example, to log in to your AWS RDS instance, run the following MySQL command:

```
$ mysql --host=RDSHOSTNAME --user=RDSUSERNAME --password=RDSPASSWORD
```

4. Run the following MySQL commands to create databases for the PAS components that require a relational database:

```
CREATE database ccd;
CREATE database notifications;
CREATE database autoscale;
CREATE database app_usage_service;
CREATE database routing;
CREATE database diego;
CREATE database account;
CREATE database nfsvolume;
CREATE database networkpolicyserver;
CREATE database silk;
CREATE database locket;
CREATE database uaa;
CREATE database credhub;
```

💡 Note: The command `CREATE database credhub;` is optional if you have no CredHub instances. By default, CredHub has `0` instances.

5. Type `exit` to quit the MySQL client, and `exit` again to close your connection to the Ops Manager VM.
6. In PAS, select **Databases**.
7. Select the **External Databases** option.

 **Note:** If you configure databases as external, you cannot configure an internal database in the **UAA** pane.

8. For **Hostname**, enter the hostname of the database server.
9. For **TCP Port**, enter the port of the database server.
10. Each component that requires a relational database has two corresponding fields: one for the database username and one for the database password. For each set of fields, specify a unique username that can access this specific database on the database server and a password for the provided username.

 **Note:** Ensure that the networkpolicyserver database user has the `ALL PRIVILEGES` permission.

11. Click **Save**.

Step 12: (Optional) Configure Internal MySQL

 **Note:** You only need to configure this section if you have selected one of the **Internal Databases - MySQL** options in the **Databases** section.

To use internal MySQL in High Availability configuration, you define a load balancer rule that lets PAS components send queries a single hostname backed by two redundant proxies. Each proxy then directs query traffic to three MySQL server nodes.

1. Allocate an internal load balancer rule to balance traffic between two static IP addresses. The static IP addresses cannot be within the range that that you have reserved for PAS.
The load balancer rule is separate from the software provided by Pivotal, and you need to define it within your infrastructure.
 - **Make your idle time out long enough to not interrupt long-running queries.** When queries take a long time, the load balancer can time out and interrupt the query.
For example, [AWS's Elastic Load Balancer](#) has a default idle timeout of 60 seconds, so queries that take longer than this duration sever the MySQL connection and return an error.
 - **Configure a healthcheck or monitor, using TCP against port 1936.** This defaults to TCP port `1936`, to maintain backwards compatibility with previous releases. This port is not configurable. Unauthenticated healthchecks against port 3306 may cause the service to become unavailable and require manual intervention to fix.
 - **Configure the load balancer to route traffic for TCP port 3306 to the IPs of all proxy instances on TCP port 3306.**
 - Record the hostname of the load balancer rule and the two static IP addresses.

 **warning:** You must configure a load balancer to achieve complete high availability.

2. From the PAS tile in Ops Manager, Select **Internal MySQL**.
3. In the **MySQL Proxy IPs** field, enter the static IP addresses used by the internal MySQL load balancer rule.

Only configure this section if you selected Internal Databases - MySQL in the previous Databases section.

A proxy tier routes MySQL connections from internal components to healthy cluster nodes. Configure DNS and/or your own load balancer to point to multiple proxy instances for increased availability. TCP healthchecks can be configured against port 1936.

The automated backups functionality works with any S3-compatible file store that can receive your backup files.

MySQL Proxy IPs

MySQL Service Hostname

4. For **MySQL Service Hostname**, enter the IP address or hostname for your load balancer. If you leave this field blank, components are configured with the IP address of the first proxy instance entered above.
5. In the **Replication canary time period** field, leave the default of 30 seconds or modify the value based on the needs of your deployment. Lower numbers cause the canary to run more frequently, which means that the canary reacts more quickly to replication failure but adds load to the database.
6. In the **Replication canary read delay** field, leave the default of 20 seconds or modify the value based on the needs of your deployment. This field configures how long the canary waits, in seconds, before verifying that data is replicating across each MySQL node. Clusters under heavy load can experience a small replication lag as write-sets are committed across the nodes.
7. (**Required**): In the **E-mail address** field, enter the email address where the MySQL service sends alerts when the cluster experiences a replication issue or when a node is not allowed to auto-rejoin the cluster.
8. To prohibit the creation of command line history files on the MySQL nodes, disable the **Allow Command History** checkbox.
9. To allow the admin and roadmin to connect from any remote host, enable the **Allow Remote Admin Access** checkbox. When the checkbox is disabled, admins must `bosh ssh` into each MySQL VM to connect as the MySQL super user.

 **Note:** Network configuration and Application Security Groups restrictions may still limit a client's ability to establish a connection with the databases.

10. For **Cluster Probe Timeout**, enter the maximum amount of time, in seconds, that a new node will search for existing cluster nodes. If left blank, the default value is 10 seconds.

Replication canary time period *

30

Replication canary read delay *

20

E-mail address (required) *

Fill in your desired email address

☒ Allow Command History

Cluster Probe Timeout

11. For **Max Connections**, enter the maximum number of connections allowed to the database. If left blank, the default value is 1500.
12. If you want to log audit events for internal MySQL, select **Enable server activity logging** under **Server Activity Logging**.
 - a. For the **Event types** field, you can enter the events you want the MySQL service to log. By default, this field includes `connect` and `query`, which tracks who connects to the system and what queries are processed.

13. Enter values for the following fields:
 - **Load Balancer Healthy Threshold**: Specifies the amount of time, in seconds, to wait until declaring the MySQL Proxy instance started. This allows an external load balancer time to register the instance as healthy.
 - **Load Balancer Unhealthy Threshold**: Specifies the amount of time, in seconds, that the MySQL Proxy continues to accept connections before shutting down. During this period, the Healthcheck reports as unhealthy to cause load balancers to fail over to other proxies. You must enter a value greater than or equal to the maximum time it takes your load balancer to consider a proxy instance unhealthy, given repeated failed healthchecks.
14. If you want to enable the MySQL interruptor feature, select the checkbox to **Prevent node auto re-join**. This feature stops all writes to the MySQL database if it notices an inconsistency in the dataset between the nodes. For more information, see the [Interruptor](#) section in the MySQL for PCF documentation.
15. Click **Save**.

For more information on how to monitor the node health of your MySQL Proxy instances, see [Using the MySQL Proxy](#).

Step 13: Configure File Storage

For production-level PCF deployments on OpenStack, the recommended selection is **External S3-Compatible**.

For more factors to consider when selecting file storage, see [Considerations for Selecting File Storage in Pivotal Cloud Foundry](#).

Internal Filestore

Internal file storage is only appropriate for small, non-production deployments.

To use the PCF internal filestore, perform the following steps:

1. In the Pivotal Application Service (PAS) tile, select **File Storage**.
2. Select **Internal WebDAV**, and click **Save**.

External S3 or Ceph Filestore

To use an external S3-compatible filestore for PAS file storage, perform the following steps:

1. In the PAS tile, select **File Storage**.
2. Select the **External S3-Compatible Filestore** option and complete the following fields:
 - Enter the `https://` **URL Endpoint** for your region.
For example, in the **us-west-2** region, enter `https://s3-us-west-2.amazonaws.com/`.
 - If you use an AWS instance profile to manage role information for your filestore, select the **S3 AWS with Instance Profile** checkbox. For more information, see [AWS Identity and Access Management](#) in the AWS documentation.

The screenshot shows a configuration form for S3. At the top, the checkbox 'S3 AWS with Instance Profile' is checked. Below it, there are two text input fields: 'Access Key (required if not using S3 AWS with Instance Profile)' and 'Secret Key (required if not using S3 AWS with Instance Profile)'. The 'Secret Key' field has a 'Secret' label and a 'Cancel' button below it.

- Alternatively, enter the **Access Key** and **Secret Key** of the `pcf-user` you created when configuring AWS for PCF. If you select the **S3 AWS with Instance Profile** checkbox and also enter an **Access Key** and **Secret Key**, the instance profile will overrule the Access Key and Secret Key.
- From the **S3 Signature Version** dropdown, select **V4 Signature**. For more information about S4 signatures, see [Signing AWS API Requests](#) in the AWS documentation.
- For **Region**, enter the region in which your S3 buckets are located. `us-west-2` is an example of an acceptable value for this field.
- Select **Server-side Encryption** to encrypt the contents of your S3 filestore. This option is only available for AWS S3.
- (Optional) If you selected **Server-side Encryption**, you can also specify a **KMS Key ID**. PAS uses the KMS key to encrypt files uploaded to the blobstore. If you do not provide a KMS Key ID, PAS uses the default AWS key. For more information, see [Protecting Data Using Server-Side Encryption with AWS KMS-Managed Keys \(SSE-KMS\)](#).
- Enter names for your S3 buckets:

| Ops Manager Field | Value | Description |
|------------------------|-----------------------|---|
| Buildpacks Bucket Name | pcf-buildpacks-bucket | This S3 bucket stores app buildpacks. |
| Droplets Bucket Name | pcf-droplets-bucket | This S3 bucket stores app droplets. Pivotal recommends that you use a unique bucket name for droplets, but you can also use the same name as above. |
| Packages Bucket Name | pcf-packages-bucket | This S3 bucket stores app packages. Pivotal recommends that you use a unique bucket name for packages, but you can also use the same name as above. |
| Resources Bucket Name | pcf-resources-bucket | This S3 bucket stores app resources. Pivotal recommends that you use a unique bucket name for app resources, but you can also use the same name as above. |

- Configure the following depending on whether your S3 buckets have versioning enabled:
 - **Versioned S3 buckets:** Enable the **Use versioning for backup and restore** checkbox to archive each bucket to a version.
 - **Unversioned S3 buckets:** Disable the **Use versioning for backup and restore** checkbox, and enter a backup bucket name for each active bucket. The backup bucket name must be different from the name of the active bucket it backs up.

☐ Use versioning for backup and restore. (All of the above buckets must have versioning enabled and use the V4 S3 Signature Version).

If versioning is not enabled or supported, you can configure separate buckets below for backups. More information at <https://docs.pivotal.io/pivotalcf/2-1/customizing/backup-restore/backup-pcf-bbr.html>.

Backup Region

Backup Buildpacks Bucket Name

Backup Droplets Bucket Name

Backup Packages Bucket Name

For more information about setting up external S3 blobstores, see the [Backup and Restore with External Blobstores](#) topic in the Cloud Foundry documentation.

3. Click **Save**.

Note: For more information regarding AWS S3 Signatures, see the [Authenticating Requests](#) topic in the AWS documentation.

Step 14: (Optional) Configure System Logging

You can configure system logging in PAS to forward log messages from PAS component VMs to an external service. Pivotal recommends forwarding logs to an external service for use in troubleshooting.

Note: The following instructions explain how to configure system logging for PAS component VMs. To forward logs from PCF tiles to an external service, you must also configure system logging in each tile. See the documentation for the given tiles for information about configuring system logging.

To configure system logging in PAS, do the following:

1. In the PAS **Settings** tab, select the **System Logging** pane. The following image shows the **System Logging** pane.

Optionally configure rsyslog to forward platform component logs to an external service. If you do not fill these fields, platform logs will not be forwarded but will remain available on the component VMs and for download via Ops Manager.

Address

Port

Transport Protocol

Encrypt syslog using TLS?*

- ☒ No
☐ Yes

Syslog Drain Buffer Size (# of messages) *

☒ Include container metrics in SysLog Drains

☒ Enable Cloud Controller security event logging

☐ Use TCP for file forwarding local transport

☒ Don't Forward Debug Logs

Custom rsyslog Configuration

Save

2. For **Address**, enter the IP address of the syslog server.
3. For **Port**, enter the port of the syslog server. The default port for a syslog server is `514`.

 **Note:** The host must be reachable from the PAS network and accept UDP or TCP connections. Ensure the syslog server listens on external interfaces.

4. For **Transport Protocol**, select a transport protocol for log forwarding.
5. For **Encrypt syslog using TLS?**, select **Yes** to use TLS encryption when forwarding logs to a remote server.
 - a. For **Permitted Peer**, enter either the name or SHA1 fingerprint of the remote peer.
 - b. For **TLS CA Certificate**, enter the TLS CA certificate for the remote server.
6. For **Syslog Drain Buffer Size**, enter the number of messages from the Loggregator Agent that the Doppler server can store before it begins to drop messages. See the [Loggregator Guide for Cloud Foundry Operators](#) topic for more details.
7. Disable the **Include container metrics in Syslog Drains** checkbox to prevent the [CF Drain CLI plugin](#) from including app container metrics in syslog drains. This feature is enabled by default.

8. Enable the **Enable Cloud Controller security event logging** checkbox to include security events in the log stream. This feature logs all API requests, including the endpoint, user, source IP address, and request result, in the Common Event Format (CEF).
9. Enable the **Use TCP for file forwarding local transport** checkbox to transmit logs over TCP. This prevents log truncation, but may cause performance issues.
10. Disable the **Don't Forward Debug Logs** checkbox to forward DEBUG syslog messages to an external service. This checkbox is enabled by default.

 **Note:** Some PAS components generate a high volume of DEBUG syslog messages. Enabling the **Don't Forward Debug Logs** checkbox prevents PAS components from forwarding the DEBUG syslog messages to external services. However, PAS still writes the messages to the local disk.

11. For **Custom rsyslog Configuration**, enter a custom syslog rule. For more information about adding custom syslog rules, see [Customizing Syslog Rules](#).
12. Click **Save**.

To configure Ops Manager for system logging, see the [Settings](#) section in the *Using the Ops Manager Interface* topic.

Step 15: (Optional) Customize Apps Manager

This section describes how to configure **Custom Branding** and **Apps Manager** to customize the appearance and functionality of Apps Manager. For more information about the **Custom Branding** configuration settings, see [Custom Branding Apps Manager](#).

1. Select **Custom Branding**. Use this section to configure the text, colors, and images of the interface that developers see when they log in, create an account, reset their password, or use Apps Manager.

Customize colors, images, and text for Apps Manager and the Cloud Foundry login portal.

3. Select **Apps Manager**.

Configure Apps Manager

☒ Enable Invitations

☐ Display Marketplace Service Plan Prices

Supported currencies as JSON *

```
{ "usd": "$", "eur": "€" }
```

Product Name

Marketplace Name

Customize Sidebar Links Add

You may configure up to 10 links in the Apps Manager sidebar.

- ▶ Marketplace 🗑
- ▶ Docs 🗑
- ▶ Tools 🗑

Apps Manager Memory Usage (MB) (min: 128)

Invitations Memory Usage (MB) (min: 256)

Apps Manager Polling Interval *

30

Apps manager polling interval in seconds. As a workaround to reduce load on the Cloud Controller API, increase the polling interval or set to 0 to stop polling. Values between 0 and 30 will default to 30 seconds.

Save

4. Select **Enable Invitations** to enable invitations in Apps Manager. Space Managers can invite new users for a given space, Org Managers can invite new users for a given org, and Admins can invite new users across all orgs and spaces. See the [Inviting New Users](#) section of the *Managing User Roles with Apps Manager* topic for more information.
5. Select **Display Marketplace Service Plan Prices** to display the prices for your services plans in the Marketplace.
6. Enter the **Supported currencies as JSON** to appear in the Marketplace. Use the format `{ "CURRENCY-CODE": "SYMBOL" }`. This defaults to `{ "usd": "$", "eur": "€" }`.
7. Use **Product Name**, **Marketplace Name**, and **Customize Sidebar Links** to configure page names and sidebar links in the **Apps Manager** and **Marketplace** pages.
8. The **Apps Manager Memory Usage (MB)** field sets the memory limit with which to deploy the Apps Manager app. Use this field to increase the memory limit if the app fails to start with an `out of memory` error.
9. The **Invitations Memory Usage (MB)** field sets the memory limit with which to deploy the Invitations app. Use this field to increase the memory limit if the app fails to start with an `out of memory` error.

10. The **Apps Manager Polling Interval** field provides a temporary fix if Apps Manager usage degrades Cloud Controller response times. In this case, you can use this field to reduce the load on the Cloud Controller and ensure Apps Manager remains available while you troubleshoot the Cloud Controller. Pivotal recommends that you do not keep this field modified as a long term fix because it can degrade Apps Manager performance. You can optionally do the following:

- Increase the polling interval above the default of `30` seconds.

 **Note:** If you enter a value between `0` and `30`, the field is automatically set to `30`.

- Disable polling by entering `0`. This stops Apps Manager from refreshing data automatically, but users can update displayed data by reloading Apps Manager manually.

11. Click **Save** to save your settings in this section.

Step 16: (Optional) Configure Email Notifications

PAS uses SMTP to send invitations and confirmations to Apps Manager users. You must complete the **Email Notifications** page if you want to enable end-user self-registration.

1. Select **Email Notifications**.

Configure Simple Mail Transfer Protocol for the Notifications application to send email notifications about your deployment. This application is deployed as an errand in Elastic Runtime. If you do not need this service, leave this section blank and disable the Notifications and Notifications UI errands.

2. Enter your reply-to and SMTP email information.

 **Note:** For GCP, you must use port `2525`. Ports `25` and `587` are not allowed on GCP Compute Engine.

3. Verify your authentication requirements with your email administrator and use the **SMTP Authentication Mechanism** dropdown to select `None`, `Plain`, or `CRAMMD5`. If you have no SMTP authentication requirements, select `None`.

- If you selected `CRAMMD5` as your authentication mechanism, enter a secret in the **SMTP CRAMMD5 secret** field.
- Click **Save**.

Note: If you do not configure the SMTP settings using this form, the administrator must create orgs and users using the cf CLI. See [Creating and Managing Users with the cf CLI](#) for more information.

Step 17: (Optional) Configure App Autoscaler

To use App Autoscaler, you must create an instance of the service and bind it to an app. To create an instance of App Autoscaler and bind it to an app, see [Set Up App Autoscaler](#) in the *Scaling an Application Using App Autoscaler* topic.

- Click **App Autoscaler**.

Configure the App Autoscaler

Autoscaler Instance Count (min: 1) *

Autoscaler API Instance Count (min: 1) *

Metric Collection Interval (min: 60, max: 3600) (min: 60, max: 3600) *

Scaling Interval (min: 15, max: 120) (min: 15, max: 120) *

☐ Verbose Logging

☐ Disable API Connection Pooling

☒ Enable Notifications

- Review the following settings:

- Autoscaler Instance Count:** How many instances of the App Autoscaler service you want to deploy. The default value is `3`. For high availability, set this number to `3` or higher. You should set the instance count to an odd number to avoid split-brain scenarios during leadership elections. Larger environments may require more instances than the default number.
- Autoscaler API Instance Count:** How many instances of the App Autoscaler API you want to deploy. The default value is `1`. Larger environments may require more instances than the default number.
- Metric Collection Interval:** How many seconds of data collection you want App Autoscaler to evaluate when making scaling decisions. The minimum interval is 60 seconds, and the maximum interval is 3600 seconds. The default value is `120`. Increase this number if the metrics you use in your scaling rules are emitted less frequently than the existing Metric Collection Interval.
- Scaling Interval:** How frequently App Autoscaler evaluates an app for scaling. The minimum interval is 15 seconds, and the maximum interval is 120 seconds. The default value is `35`.
- Verbose Logging** (checkbox): Enables verbose logging for App Autoscaler. Verbose logging is disabled by default. Select this checkbox to see more detailed logs. Verbose logs show specific reasons why App Autoscaler scaled the app, including information about minimum and maximum instance limits, App Autoscaler's status. For more information about App Autoscaler logs, see [App Autoscaler Events and Notifications](#).
- Disable API Connection Pooling:** API connection pooling increases performance by reducing the cost associated with establishing new connections. If you do not want to keep connections open for reuse, select this option.

3. Click **Save**.

Step 18: Configure Cloud Controller

1. Click **Cloud Controller**.

Configure the Cloud Controller

Cloud Controller DB Encryption Key

Secret

Enabling CF API Rate Limiting will prevent API consumers from overwhelming the platform API servers. Limits are imposed on a per-user or per-client basis and reset on an hourly interval. *

☐ Enable
 ☒ Disable

Save

2. Enter your **Cloud Controller DB Encryption Key** if all of the following are true:

- You deployed Pivotal Application Service (PAS) previously.
- You then stopped PAS or it crashed.
- You are re-deploying PAS with a backup of your Cloud Controller database.

See [Backing Up Pivotal Cloud Foundry](#) for more information.

3. CF API Rate Limiting prevents API consumers from overwhelming the platform API servers. Limits are imposed on a per-user or per-client basis and reset on an hourly interval.

To disable CF API Rate Limiting, select **Disable** under **Enable CF API Rate Limiting**. To enable CF API Rate Limiting, perform the following steps:

- Under **Enable CF API Rate Limiting**, select **Enable**.
- For **General Limit**, enter the number of requests a user or client is allowed to make over an hour interval for all endpoints that do not have a custom limit. The default value is `2000`.
- For **Unauthenticated Limit**, enter the number of requests an unauthenticated client is allowed to make over an hour interval. The default value is `100`.

4. Click **Save**.

Step 19: Configure Smoke Tests

The Smoke Tests errand runs basic functionality tests against your Pivotal Application Service (PAS) deployment after an installation or update. In this section, choose where to run smoke tests. In the **Errands** section, you can choose whether or not to run the Smoke Tests errand.

1. Select **Smoke Tests**.
2. If you have a shared apps domain, select **Temporary space within the system organization**, which creates a temporary space within the `system` organization for running smoke tests and deletes the space afterwards. Otherwise, select **Specified org and space** and complete the fields to specify where you want to run smoke tests.

Specify a Cloud Foundry organization and space where smoke tests can run if in the future you delete your Elastic Runtime deployment domains.

Choose where to deploy applications when running the smoke tests *

- ☐ Temporary space within the system organization (This is deleted after smoke tests finish.)
- ☒ Specified org and space (The org and space must have a domain available for routing.)

Organization *

Space *

Domain *

Save

3. Click **Save**.

Step 20: (Optional) Enable Advanced Features

The **Advanced Features** section of Pivotal Application Service (PAS) includes new functionality that may have certain constraints. Although these features are fully supported, Pivotal recommends caution when using them in production environments.

Diego Cell Memory and Disk Overcommit

If your apps do not use the full allocation of disk space and memory set in the **Resource Config** tab, you might want use this feature. These fields control the amount to overcommit disk and memory resources to each Diego Cell VM.

For example, you might want to use the overcommit if your apps use a small amount of disk and memory capacity compared to the amounts set in the **Resource Config** settings for **Diego Cell**.

Note: Due to the risk of app failure and the deployment-specific nature of disk and memory use, Pivotal has no recommendation about how much, if any, memory or disk space to overcommit.

To enable overcommit, do the following:

1. Select **Advanced Features**.

Cell Memory Capacity (MB) (min: 1)

Cell Disk Capacity (MB) (min: 1)

2. Enter the total desired amount of Diego cell memory value in the **Cell Memory Capacity (MB)** field. Refer to the **Diego Cell** row in the **Resource Config** tab for the current Cell memory capacity settings that this field overrides.
3. Enter the total desired amount of Diego cell disk capacity value in the **Cell Disk Capacity (MB)** field. Refer to the **Diego Cell** row in the **Resource Config** tab for the current Cell disk capacity settings that this field overrides.
4. Click **Save**.

 **Note:** Entries made to each of these two fields set the total amount of resources allocated, not the overage.

Whitelist for Non-RFC-1918 Private Networks

Some private networks require extra configuration so that internal file storage (WebDAV) can communicate with other PCF processes.

The **Whitelist for non-RFC-1918 Private Networks** field is provided for deployments that use a non-RFC 1918 private network. This is typically a private network other than `10.0.0.0/8`, `172.16.0.0/12`, or `192.168.0.0/16`.

Most PCF deployments do not require any modifications to this field.

To add your private network to the whitelist, do the following:

1. Select **Advanced Features**.
2. Append a new `allow` rule to the existing contents of the **Whitelist for non-RFC-1918 Private Networks** field.

Whitelist for non-RFC-1918 Private Networks *

allow 10.0.0.0/8;;allow 172.16.0.0/12;;allow .

If your Elastic Runtime deployment is using a private network that is not RFC 1918 (10.0.0.0/8, 172.16.0.0/12, 192.168.0.0/16), then you must type in "allow <your-network>;" here. It is important to include the word "allow" and the semi-colon at the end. For example, "allow 172.99.0.0/24;"

Include the word `allow`, the network CIDR range to allow, and a semi-colon (`;`) at the end. For example: `allow 172.99.0.0/24;`

3. Click **Save**.

CF CLI Connection Timeout

The **CF CLI Connection Timeout** field allows you to override the default five second timeout of the Cloud Foundry Command Line Interface (cf CLI) used within your PCF deployment. This timeout affects the cf CLI command used to push PAS errand apps such as Notifications, Autoscaler, and Apps Manager.

Set the value of this field to a higher value, in seconds, if you are experiencing domain name resolution timeouts when pushing errands in PAS.

To modify the value of the **CF CLI Connection Timeout**, perform the following steps:

1. Select **Advanced Features**.

CF CLI Connection Timeout

15

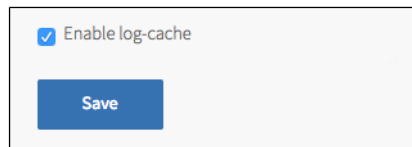

2. Add a value, in seconds, to the **CF CLI Connection Timeout** field.
3. Click **Save**.

Log Cache

Log Cache is an in-memory caching layer for logs and metrics. This Loggregator feature lets users filter and query logs through a CLI or API endpoints. Cached logs are available on demand. For more information about Log Cache, see [Enable Log Cache](#) in the *Configuring Logging in PASTopic*.

To configure the **Enable log-cache** checkbox, do the following:

1. Select **Advanced Features**.

2. Select or deselect the **Enable log-cache** checkbox.
3. Click **Save**.

Database Connection Limits

You can configure the maximum number of concurrent database connections that diego and container networking components can have. Use the field beginning with **Maximum number of open connections...** for a given component. The placeholder values for each field are the default values.

When there are not enough connections available, such as during a time of heavy load, components may experience degraded performance and sometimes failure. To resolve or prevent this, you can increase and fine-tune database connection limits for the component.

⚠ warning: Decreasing the value of this field for a component may affect the amount of time it takes for it to respond to requests.

Step 21: Configure Errands

Errands are scripts that Ops Manager runs automatically when it installs or uninstalls a product, such as a new version of Pivotal Application Service (PAS). There are two types of errands: *post-deploy errands* run after the product is installed, and *pre-delete errands* run before the product is uninstalled.

By default, Ops Manager always runs all errands.

The PAS tile **Errands** pane lets you change these run rules. For each errand, you can select **On** to run it always or **Off** to never run it.

For more information about how Ops Manager manages errands, see the [Managing Errands in Ops Manager](#) topic.

💡 Note: Several errands, such as App Autoscaler and Notifications, deploy apps that provide services for your deployment. When one of these apps is running, selecting **Off** for the corresponding errand on a subsequent installation does not stop the app.

- **Smoke Test Errand** verifies that your deployment can do the following:
 - Push, scale, and delete apps
 - Create and delete orgs and spaces
- **Usage Service Errand** deploys the Pivotal Usage Service application, which Apps Manager depends on.
- **Apps Manager Errand** deploys Apps Manager, a dashboard for managing apps, services, orgs, users, and spaces. Until you deploy Apps Manager, you must perform these functions through the cf CLI. After Apps Manager has been deployed, Pivotal recommends setting this errand to **Off** for subsequent PAS deployments. For more information about Apps Manager, see the [Getting Started with the Apps Manager](#) topic.
- **Notifications Errand** deploys an API for sending email notifications to your PCF platform users.

💡 Note: The Notifications app requires that you [configure SMTP](#) with a username and password, even if you set the value of **SMTP Authentication Mechanism** to `none`.

- **Notifications UI Errand** deploys a dashboard for users to manage notification subscriptions.
- **App Autoscaler Errand** enables you to configure your apps to automatically scale in response to changes in their usage load. See the [Scaling an Application Using Autoscaler](#) topic for more information.
- **NFS Broker Errand** enables you to use NFS Volume Services by installing the NFS Broker app in PAS. See the [Enabling NFS Volume Services](#) topic for more information.

Step 22: Enable Traffic to Private Subnet

Unless you are using your own load balancer, you must enable traffic flow to the OpenStack private subnet as follows. Give each HAProxy a way of routing traffic into the private subnet by providing public IP addresses as floating IP addresses.

1. Click **Resource Config**.

Resource Config

| JOB | INSTANCES | PERSISTENT DISK TYPE | VM TYPE | LOAD BALANCERS | INTERNET CONNECTED |
|-------------------------------|--------------|----------------------|---|----------------|-------------------------------------|
| Consul | 1 | Automatic: 1 GB | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| NATS | 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| File Storage | Automatic: 1 | Automatic: 100 GB | Automatic: medium.mem (cpu: 1, ram: 6 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| MySQL Proxy | 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| MySQL Server | 1 | Automatic: 100 GB | Automatic: large.disk (cpu: 2, ram: 8 GB, disk: 64 GB) | | <input checked="" type="checkbox"/> |
| Backup Prepare Node | Automatic: 1 | Automatic: 200 GB | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| Diego BBS | 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| UAA | 1 | None | Automatic: medium.disk (cpu: 2, ram: 4 GB, disk: 32 GB) | | <input checked="" type="checkbox"/> |
| Cloud Controller | 1 | None | Automatic: medium.disk (cpu: 2, ram: 4 GB, disk: 32 GB) | | <input checked="" type="checkbox"/> |
| HAProxy | Automatic: 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| Router | 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | pcf-web-elb | <input checked="" type="checkbox"/> |
| MySQL Monitor | Automatic: 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| Clock Global | Automatic: 1 | None | Automatic: medium.disk (cpu: 2, ram: 4 GB, disk: 32 GB) | | <input checked="" type="checkbox"/> |
| Cloud Controller Worker | 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| Diego Brain | 1 | Automatic: 1 GB | Automatic: small (cpu: 1, ram: 2 GB, disk: 8 GB) | pcf-ssh-elb | <input checked="" type="checkbox"/> |
| Diego Cell | 1 | None | Automatic: xlarge.disk (cpu: 4, ram: 16 GB, disk: 128 GB) | | <input checked="" type="checkbox"/> |
| Loggregator Trafficcontroller | 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| Syslog Adapter | 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| Syslog Scheduler | 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| Doppler Server | 1 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| TCP Router | 0 | Automatic: 1 GB | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | pcf-tcp-elb | <input checked="" type="checkbox"/> |
| CredHub | Automatic: 0 | None | Automatic: large (cpu: 2, ram: 8 GB, disk: 16 GB) | | <input checked="" type="checkbox"/> |

Save

2. Enter one or more IP addresses in **Floating IPs** for each HAProxy.

3. (Optional) If you have enabled the TCP Routing feature, enter one or more IP addresses in **Floating IPs** column for each TCP Router.

4. Click **Save**.

Step 23: (Optional) Scale Down and Disable Resources

Note: The **Resource Config** pane has fewer VMs if you are installing the [Small Footprint Runtime](#).

Note: The Small Footprint Runtime does not default to a highly available configuration. It defaults to the minimum configuration. If you want to make the Small Footprint Runtime highly available, scale the **Compute**, **Router**, and **Database** VMs to **3** instances and scale the **Control** VM to **2** instances.

Pivotal Application Service (PAS) defaults to a highly available resource configuration. However, you may need to perform additional procedures to make your deployment highly available. See the [Zero Downtime Deployment and Scaling in CF](#) and the [Scaling Instances in PAS](#) topics for more information.

If you do not want a highly available resource configuration, you must scale down your instances manually by navigating to the **Resource Config** section and using the dropdowns under **Instances** for each job.

By default, PAS also uses an internal filestore and internal databases. If you configure PAS to use external resources, you can disable the corresponding system-provided resources in Ops Manager to reduce costs and administrative overhead.

To disable specific VMs in Ops Manager, do the following:

1. Click **Resource Config**.
2. If you configured PAS to use an external S3-compatible filestore, enter **0** in **Instances** in the **File Storage** field.
3. If you selected **External** when configuring the UAA, System, and CredHub databases, edit the following fields:

- MySQL Proxy: Enter in **Instances**.
- MySQL Server: Enter in **Instances**.
- MySQL Monitor: Enter in **Instances**.

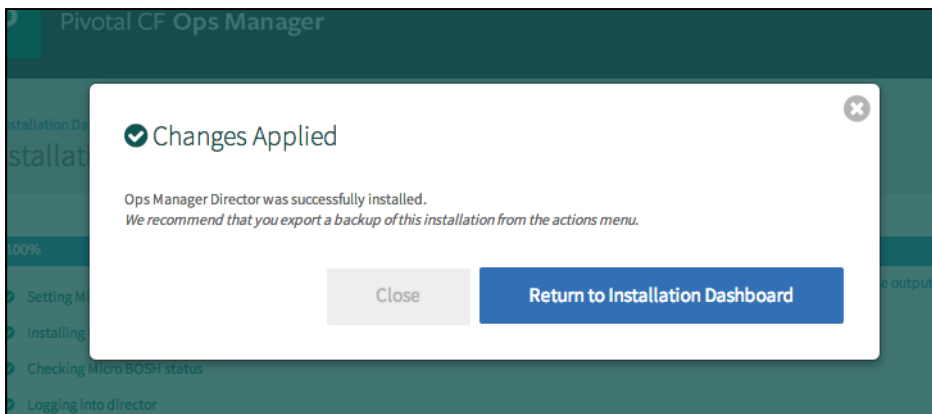

- If you disabled TCP routing, enter **Instances** in the **TCP Router** field.
- If you are not using HAProxy, enter **Instances** in the **HAProxy** field.
- Click **Save**.

Step 24: Complete PAS Installation

- Click the **Installation Dashboard** link to return to the Installation Dashboard.
- Click **Apply Changes**. If the following ICMP error message appears, click **Ignore errors and start the install**.

- PAS installs. The image shows the **Changes Applied** message that Ops Manager displays when the installation process successfully completes.

Return to [Installing Pivotal Cloud Foundry on OpenStack](#).

PCF on vSphere Requirements

Page last updated:

This guide describes how to install [Pivotal Cloud Foundry](#) (PCF) on vSphere.

If you experience a problem while following the steps below, refer to the [Known Issues](#) topics or to [Diagnosing Problems in PCF](#).

General Requirements

The following are general requirements for deploying and managing a PCF deployment with Ops Manager and Pivotal Application Service (PAS):

- A wildcard DNS record that points to your router or load balancer. Alternatively, you can use a service such as xip.io. For example, `203.0.113.0.xip.io`.
 - PAS gives each application its own hostname in your app domain.
 - With a wildcard DNS record, every hostname in your domain resolves to the IP address of your router or load balancer, and you do not need to configure an A record for each app hostname. For example, if you create a DNS record `*.example.com` pointing to your load balancer or router, every application deployed to the `example.com` domain resolves to the IP address of your router.
- At least one wildcard TLS certificate that matches the DNS record you set up above, `*.example.com`.
- Sufficient IP allocation:
 - One static IP address for either HAProxy or one of your gorouters
 - One static IP address for each job in the Ops Manager tile. See the Resource Config pane for each tile for a full list.
 - One static IP address for each job listed below:
 - Consul
 - NATS
 - File Storage
 - MySQL Proxy
 - MySQL Server
 - Backup Prepare Node
 - HAProxy
 - Router
 - MySQL Monitor
 - Diego Brain
 - TCP Router
 - One IP for each VM instance created by the service.
 - An additional IP address for each compilation worker. So the formula for total IPs needed is

$$\text{IPs needed} = \text{static IPs} + \text{VM instances} + \text{compilation workers}$$

Note: Pivotal recommends that you allocate at least 36 dynamic IP addresses when deploying Ops Manager and PAS. BOSH requires additional dynamic IP addresses during installation to compile and deploy VMs, install PAS, and connect to services.

- One or more NTP servers if not already provided by your IaaS.
- (**Recommended**) A network without DHCP available for deploying the PAS VMs.

Note: If you have DHCP, refer to the [Troubleshooting Guide](#) to avoid issues with your installation.

- (**Optional**) External storage. When you deploy PCF, you can select internal file storage or external file storage, either network-accessible or IaaS-provided, as an option in the PAS tile. Pivotal recommends using external storage whenever possible. See [Configure File Storage](#) for a discussion of how file storage location affects platform performance and stability during upgrades.
- (**Optional**) External databases. When you deploy PCF, you can select internal or external databases for the BOSH Director and for PAS. Pivotal recommends using external databases in production deployments. An external database must be configured to use the UTC timezone.
- (**Optional**) External user stores. When you deploy PCF, you can select a SAML user store for Ops Manager or a SAML or LDAP user store for PAS, to integrate existing user accounts.
- The most recent version of the [Cloud Foundry Command Line Interface](#) (cf CLI).

vSphere Requirements

 **Note:** If you are using the Cisco Nexus 1000v Switch, refer to the [Using the Cisco Nexus 1000v Switch with Ops Manager](#) topic for more information.

 **Note:** When installing Ops Manager on a vSphere environment with multiple ESXi hosts, you must use network-attached or shared storage devices. Local storage devices do not support sharing across multiple ESXi hosts.

Minimum Resource Requirements for PCF Deployment with Pivotal Application Service

The following are the minimum resource requirements for maintaining a [Pivotal Cloud Foundry](#) (PCF) deployment with Ops Manager and Pivotal Application Service (PAS) on vSphere:

- vSphere v6.7*, v6.5, v6.0, or v5.5
- Disk space: 2 TB recommended
- Memory: 120 GB
- Two public IP addresses: One for PAS and one for Ops Manager
- vCPU cores: 80
- Overall CPU: 28 GHz
- vSphere editions: standard and above
- Ops Manager must have HTTPS access to vCenter and ESX hosts on TCP port 443.
- A configured vSphere cluster:
 - If you enable vSphere DRS (Distributed Resource Scheduler) for the cluster, you must set the Automation level to **Partially automated** or **Fully automated**. If you set the Automation level to **Manual**, the BOSH automated installation will fail with a `power_on_vm` error when BOSH attempts to create virtual machines (VMs).
 - Disable hardware virtualization if your vSphere hosts do not support VT-X/EPT. If you are unsure whether the VM hosts support VT-x/EPT, you should disable this setting. If you leave this setting enabled and the VM hosts do not support VT-x/EPT, then each VM requires manual intervention in vCenter to continue powering on without the Intel virtualized VT-x/EPT. Refer to the vCenter help topic at [Configuring Virtual Machines > Setting Virtual Processors and Memory > Set Advanced Processor Options](#) for more information.
- If you configure an external load balancer, an HTTP keepalive connection timeout greater than five seconds

* Use Ops Manager v2.2.5 or later to deploy PCF on vSphere v6.7.

 **Note:** If you are deploying PCF behind a firewall, see the [Preparing Your Firewall for Deploying Pivotal Cloud Foundry](#) topic.

Minimum Resource Requirements for PCF Deployment with Small Footprint PAS

The following are the minimum resource requirements for maintaining a PCF deployment with Ops Manager and Small Footprint PAS on vSphere:

- 1 vSphere cluster/1 AZ
- 2 resource pools: 1 for NSX-T components and 1 for PAS or PKS
- 3 hosts minimum for vSphere HA (4 hosts for vSphere VSAN)
- Shared storage/VSAN
- 1 NSX Manager
- 3 NSX controllers
- 4 large edge VMs in a cluster
- PCF: Ops Manager, the BOSH Director, and Small Footprint PAS

Instance Number and Scaling Requirements

By default, PAS deploys the number of VM instances required to run a highly available configuration of PCF. If you are deploying a test or sandbox PCF that does not require HA, then you can scale down the number of instances in your deployment.

For information about the number of instances required to run a minimal, non-HA PCF deployment, see [Scaling PAS](#).

vSphere Service Account Requirements

Ops Manager requires read/write permissions to the datacenter level of the [vSphere Inventory Hierarchy](#) to successfully install. Pivotal recommends defining a custom role for the service account that has all privileges for all objects in the datacenter, including propagating privileges to children.

For a complete list of the minimum required vSphere privileges, see the [vSphere Service Account Requirements](#) topic.

Since Ops Manager passes all required credentials through to BOSH, you only need one service account with the required vSphere privileges to complete the installation. Setting up separate service accounts for Ops Manager and BOSH is not necessary or recommended.

 **Note:** You can also apply the default [VMware Administrator System Role](#) to the service account to achieve the appropriate permission level.

vSphere Security Documents

- [vSphere Security guide \(PDF\)](#) 
This guide contains best practices for securing and managing a vSphere installation.

Step 1: Install Ops Manager

Complete the following procedures to install Ops Manager on vSphere:

1. [Deploying Ops Manager to vSphere](#)
2. [Configuring BOSH Director on vSphere](#)

(Optional) Step 2: Install the IPsec Add-on

The PCF IPsec add-on secures network traffic within a PCF deployment and provides internal system protection if a malicious actor breaches your firewall. See the [Securing Data in Transit with the IPsec Add-on](#) topic for installation instructions.

 **Note:** You must install the PCF IPsec add-on before installing any other tiles to enable the IPsec functionality. Pivotal recommends installing IPsec immediately after Ops Manager, and before installing the PAS tile.

(Optional) Step 3: Install the NSX-T Tile

The NSX-T tile provides a single network for containers, VMs, and other entities. It enables NSX to enforce C2C policy and operators to configure additional policies through NSX Manager.

- You must install the NSX-T tile after you install or upgrade the BOSH Director tile.
- You must install the NSX-T tile before you install or upgrade the PAS tile.

See the [NSX-T Container Plug-In for Kubernetes and Cloud Foundry - Installation and Administration Guide](#) for more information.

Step 4: Install PAS

To install PAS on vSphere, perform the procedures in the [Deploying PAS on vSphere](#) topic.

Step 5: Create New User Accounts

Once you have successfully deployed PCF, add users to your account. Refer to the [Creating New PAS User Accounts](#) topic for more information.

Step 6: Target Your Deployment

Use the Cloud Foundry Command Line Interface (cf CLI) to target your deployment. If you have not installed the cf CLI, follow the instructions in [Installing the cf CLI](#). For more information about the cf CLI, see [Getting Started with the cf CLI](#).

 **Note:** To obtain the UAA admin name and password, refer to PAS **Credentials** in Ops Manager. You can also use the user that you created in Apps Manager, or create another user with the `create-user` command.

Additional Configuration

See the following topics for additional configuration information:

- [Deploying PAS with NSX-T Networking](#)
- [Provisioning a Virtual Disk in vSphere](#)
- [Using the Cisco Nexus 1000v Switch with Ops Manager](#)
- [Using BOSH Resurrector and vSphere HA](#)
- [Configuring SSL Termination for vSphere Deployments](#)
- [Availability Zones in vSphere](#)
- [Updating NSX Security Group and Load Balancer Information](#)

vSphere Service Account Requirements

Page last updated:

This topic describes the minimum privileges required by the vSphere BOSH CPI. A vSphere admin must grant the following privileges to the vSphere service account that Pivotal Cloud Foundry (PCF) uses to manage vSphere resources.

The PCF account needs privileges at both the vCenter server level and the Datacenter level. See [Hierarchical Inheritance of Permissions](#) in the VMware documentation for how permission levels and inheritance work in vSphere.

vCenter-Level Privileges

Ops Manager assigns custom attributes to the virtual machines (VMs) it deploys to identify BOSH releases and job index information about each VM. vCenter APIs require vCenter server level access to manage these custom attributes.

The following table summarizes the privileges that a PCF account requires at the vCenter Server instance level. Some of these privileges are inherited, and others must be granted by a vCenter admin:

| Object | Privilege (UI) | Privilege (API) |
|------------------------|--------------------------|---------------------------|
| Role | Read-only | System.Anonymous |
| | | System.Read |
| | | System.View |
| Global | Manage custom attributes | Global.ManageCustomFields |
| | Register Extensions | Extension.Register |
| Profile-Driven Storage | Profile-driven Storage | StorageProfile.Update |
| | | StorageProfile.View |

Datacenter-Level Privileges

The following privileges must be set at the data center level:

| Object | Privilege (UI) | Privilege (API) |
|-----------|---------------------------|--------------------------|
| Datastore | Low level file operations | Datastore.FileManagement |
| Network | Assign network | Network.Assign |

Folder and Datastore-Level Privileges

You must grant the following privileges on any entities in a datacenter where you will deploy PCF:

Datastore Object

| Privilege (UI) | Privilege (API) |
|------------------------------|-------------------------------------|
| Allocate space | Datastore.AllocateSpace |
| Browse datastore | Datastore.Browse |
| Remove file | Datastore.DeleteFile |
| Update virtual machine files | Datastore.UpdateVirtualMachineFiles |

Folder Object

Ops Manager creates a folder for VMs, stemcells, and persistent disks during installation. The folder contents change frequently as Ops Manager applies

changes.

| Privilege (UI) | Privilege (API) |
|----------------|-----------------|
| Delete folder | Folder.Delete |
| Create folder | Folder.Create |
| Move folder | Folder.Move |
| Rename folder | Folder.Rename |

Inventory Service Object

| Privilege (UI) | Privilege (API) |
|--------------------------------------|------------------------------------|
| vSphere Tagging > Create vSphere Tag | InventoryService.Tagging.CreateTag |
| vSphere Tagging > Delete vSphere Tag | InventoryService.Tagging.EditTag |
| vSphere Tagging > Edit vSphere Tag | InventoryService.Tagging.DeleteTag |

Resource Object

When using [vAppImport](#) to clone a VM, BOSH requires the resource migration privileges to create a new, powered-off VM based on a given stemcell. BOSH migrates the VM to the destination datastore, where Ops Manager deploys the VM and powers it on.

| Privilege (UI) | Privilege (API) |
|---|-------------------------|
| Assign virtual machine to resource pool | Resource.AssignVMToPool |
| Migrate powered off virtual machine | Resource.ColdMigrate |
| Migrate powered on virtual machine | Resource.HotMigrate |

Virtual Machine Object

Configuration

| Privilege (UI) | Privilege (API) |
|-----------------------------|---------------------------------------|
| Add existing disk | VirtualMachine.Config.AddExistingDisk |
| Add new disk | VirtualMachine.Config.AddNewDisk |
| Add or remove device | VirtualMachine.Config.AddRemoveDevice |
| Advanced | VirtualMachine.Config.AdvancedConfig |

Inventory

| Privilege (UI) | Privilege (API) |
|----------------------|---|
| Create from existing | VirtualMachine.Inventory.CreateFromExisting |
| Create new | VirtualMachine.Inventory.Create |
| Move | VirtualMachine.Inventory.Move |
| Remove | VirtualMachine.Inventory.Delete |

Provisioning

When cloning a stemcell, BOSH sets custom specifications, such as hostnames and network configurations, based on the stemcell operating system.

The VM download privilege allows BOSH to modify files within a VM, including links between VMs and persistent disks. When vMotion migrates disks in vSphere, BOSH uses these links to maintain the connections between VMs and their persistent disks.

| Privilege (UI) | Privilege (API) |
|------------------------------------|--|
| Allow disk access | VirtualMachine.Provisioning.DiskRandomAccess |
| Allow read-only disk access | VirtualMachine.Provisioning.DiskRandomRead |
| Allow virtual machine download | VirtualMachine.Provisioning.GetVmFiles |
| Allow virtual machine files upload | VirtualMachine.Provisioning.PutVmFiles |
| Clone template | VirtualMachine.Provisioning.CloneTemplate |
| Clone virtual machine | VirtualMachine.Provisioning.Clone |
| Customize | VirtualMachine.Provisioning.Customize |

| | |
|------------------------------------|---|
| Deploy template | VirtualMachine.Provisioning.DeployTemplate |
| Mark as template | VirtualMachine.Provisioning.MarkAsTemplate |
| Mark as virtual machine | VirtualMachine.Provisioning.MarkAsVM |
| Modify customization specification | VirtualMachine.Provisioning.ModifyCustSpecs |
| Promote disks | VirtualMachine.Provisioning.PromoteDisks |
| Read customization specifications | VirtualMachine.Provisioning.ReadCustSpecs |

Snapshot Management

Before Ops Manager deploys a new VM, it uses a snapshot to clone the stemcell image to the destination.

| Privilege (UI) | Privilege (API) |
|-----------------|---------------------------------------|
| Create snapshot | VirtualMachine.State.CreateSnapshot |
| Remove snapshot | VirtualMachine.State.RemoveSnapshot |
| Rename snapshot | VirtualMachine.State.RenameSnapshot |
| Revert snapshot | VirtualMachine.State.RevertToSnapshot |

vApp Object

These privileges must be set at the resource pool level. `VApp.ApplicationConfig` is required when attaching or detaching persistent disks.

| Privilege (UI) | Privilege (API) |
|--------------------------------|------------------------|
| Import | VApp.Import |
| vApp application configuration | VApp.ApplicationConfig |

Deploying Ops Manager on vSphere

Page last updated:

This topic provides instructions for deploying Ops Manager on VMware vSphere.

Warning: If you are installing Pivotal Container Service (PKS) on vSphere with NSX-T integration, follow the instructions in [Deploying Ops Manager with NSX-T for PKS](#) instead of performing the steps provided in this topic.

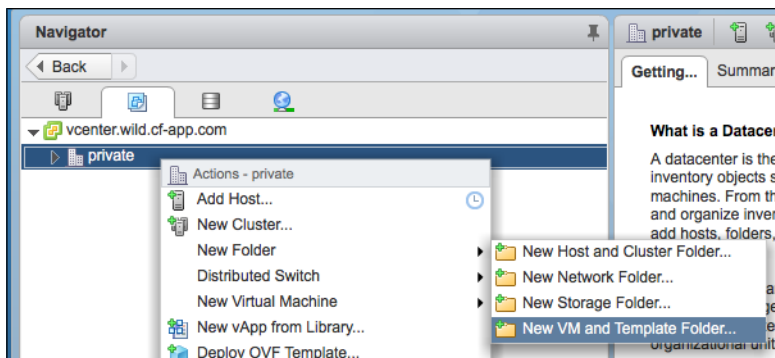

Note: The instructions in this topic are based on vSphere 6.5.

Deploy Ops Manager

1. Download Pivotal Cloud Foundry Ops Manager for vSphere from [Pivotal Network](#).
2. Log in to vCenter.

3. In the **Navigator**, click the **VMs and Templates** tab.
4. Right click your datacenter.
 - a. Select **New Folder > New VM and Template Folder**.

- b. Name the folder `pivotal_cf`.
 - c. Click **Ok**.
5. Click your newly created folder.
 6. Click the **Deploy OVF Template** icon and complete the following steps:

Note: The vSphere Web Client requires Flash. If the **Deploy OVF Template** button is unresponsive, ensure that you have Flash enabled in your browser and reload the page.

a. Select template

- i. Click **Browse** and select the `.ova` file that you downloaded from Pivotal Network.
- ii. Click **Next**.

b. Select name and location

- i. Name the virtual machine and click **Next**.

Note: The selected folder is the one that you created.

c. Select a resource

- i. Select the resource that you want to use to launch the VM and click **Next**.

Note: Hardware virtualization must be off if your vSphere host does not support VT-x/EPT.

d. Review Details

- i. Verify the template details and click **Next**.

e. Select storage

- i. Select a disk format. For information about disk formats, see [Provisioning a Virtual Disk](#).

warning: Ops Manager requires a Director VM with at least 8 GB memory.

- ii. Select a storage destination.
- iii. Click **Next**.

f. Select networks

- i. Select a network from the drop down list and click **Next**.

g. Customize template

- i. In the **Admin Password** field, enter a default password for the account with the username `ubuntu`. Alternatively, you can enter a pre-existing SSH key value in the **Public SSH Key** field.

Note: You must specify a default password, an SSH key, or both. If you do not have either of these fields configured, Ops Manager will not boot up.

- ii. Complete the remaining network information and passwords for the Ops Manager VM admin user.

Note: Record this network information. The IP Address will be the location of the Ops Manager interface.

- iii. Click **Next**.

h. Ready to complete

- i. Review the configuration data and click **Finish**.
7. With the VM selected, click **Actions > Power > Power On**. Once the VM boots, the interface is available at the IP address that you specified.

Note: It is normal to experience a brief delay before the interface is accessible while the web server and VM start up.

8. Create a DNS entry for the IP address that you used for Ops Manager. You must use this fully qualified domain name when you log in to Ops Manager as described in the [Set Up Ops Manager](#) section of *Configuring BOSH Director on vSphere*.

Next Steps

After you complete this procedure, follow the instructions in [Configuring BOSH Director on vSphere](#).

[Return to the Installing Pivotal Cloud Foundry Guide](#) [↗](#)

Configuring BOSH Director on vSphere

Page last updated:

This topic describes how to configure the BOSH Director tile for VMware vSphere. You can also perform the procedures in this topic using the Ops Manager API. For more information, see [Using the Ops Manager API](#).

⚠ warning: If you are installing Pivotal Container Service (PKS) on vSphere with NSX-T integration, follow the instructions in [Configuring BOSH Director with NSX-T for PKS](#) instead of performing the steps provided in this topic.

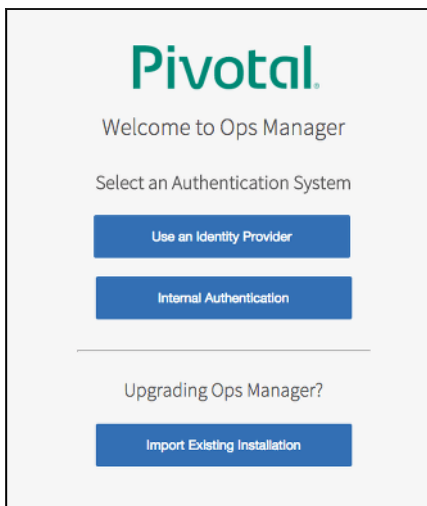

Prerequisites

Before you begin this procedure, you must complete all steps in [Deploying Ops Manager on vSphere](#).

💡 Note: Pivotal strongly recommends installing PAS and PKS on separate instances of Ops Manager for security reasons. For more information, see [PAS and PKS Deployments with Ops Manager](#).

Step 1: Set Up Ops Manager

1. In a web browser, navigate to the fully qualified domain of your Ops Manager.
2. When Ops Manager starts for the first time, you must choose one of the following:
 - [Use an Identity Provider](#): If you choose **Use an Identity Provider**, an external identity server maintains your user database.
 - [Internal Authentication](#): If you choose **Internal Authentication**, Ops Manager maintains your user database.

Use an Identity Provider

1. Log in to your IdP console and download the IdP metadata XML. Optionally, if your IdP supports metadata URL, you can copy the metadata URL instead of the XML.

2. Copy the IdP metadata XML or URL to the Ops Manager **Use an Identity Provider** login page.

Note: The same IdP metadata URL or XML is applied for the BOSH Director. If you use a separate IdP for BOSH, copy the metadata XML or URL from that IdP and enter it into the BOSH IdP Metadata text box in the Ops Manager login page.

3. Enter values for the fields listed below. Failure to provide values in these fields results in a `500` error.

Note: These attributes are case-sensitive.

- **SAML admin group:** Enter the name of the SAML group that contains all Ops Manager administrators.
- **SAML groups attribute:** Enter the groups attribute tag name with which you configured the SAML server.

4. Enter your **Decryption passphrase**. Read the **End User License Agreement**, and select the checkbox to accept the terms.

5. Your Ops Manager login page appears. Enter your username and password. Click **Login**.

6. Download your SAML Service Provider metadata (SAML Relying Party metadata) by navigating to the following URLs:

- **6a.** Ops Manager SAML service provider metadata: `https://OPS-MAN-FQDN:443/uaa/saml/metadata`
- **6b.** BOSH Director SAML service provider metadata: `https://BOSH-IP-ADDRESS:8443/saml/metadata`

Note: To retrieve your `BOSH-IP-ADDRESS`, navigate to the **BOSH Director** tile > **Status** tab. Record the **BOSH Director** IP address.

7. Configure your IdP with your SAML Service Provider metadata. Import the Ops Manager SAML provider metadata from Step 6a above to your IdP. If your IdP does not support importing, provide the values below.

- **Single sign on URL:** `https://OPS-MAN-FQDN:443/uaa/saml/SSO/alias/OPS-MAN-FQDN`
- **Audience URI (SP Entity ID):** `https://OP-MAN-FQDN:443/uaa`
- **Name ID:** Email Address
- SAML authentication requests are always signed

8. Import the BOSH Director SAML provider metadata from Step 6b to your IdP. If the IdP does not support an import, provide the values below.

- **Single sign on URL:** `https://BOSH-IP:8443/saml/SSO/alias/BOSH-IP`
- **Audience URI (SP Entity ID):** `https://BOSH-IP:8443`
- **Name ID:** Email Address
- SAML authentication requests are always signed

9. Return to the **BOSH Director** tile, and continue with the configuration steps below.

Use Internal Authentication

1. When redirected to the **Internal Authentication** page, you must complete the following steps:

- Enter a **Username**, **Password**, and **Password confirmation** to create an Admin user.
- Enter a **Decryption passphrase** and the **Decryption passphrase confirmation**. This passphrase encrypts the Ops Manager datastore, and is not

recoverable.

- If you are using an **HTTP proxy** or **HTTPS proxy**, follow the instructions in [Configuring Proxy Settings for the BOSH CPI](#).
- Read the **End User License Agreement**, and select the checkbox to accept the terms.
- Click **Setup Authentication**.

Step 2: vCenter Configs Page

1. Log in to Ops Manager with the Admin username and password that you created in the previous step.
2. Click the **BOSH Director** tile.
3. Select **vCenter Config**. Configure the one or more vCenters that host your PCF foundation. The following image shows the **vCenter Config** pane.

✓ vCenter Configs

✓ Director Config

✓ Create Availability Zones

✓ Create Networks

✓ Assign AZs and Networks

✓ Security

✓ Syslog

concourse-bulldog_specs_templates

Disk path Folder*

concourse-bulldog_specs_disk

Save

4. Complete the fields on the vCenter Config pane as follows:

- **Name:** A name that you provide for your vCenter configuration. This field is used to identify the datacenter configuration in Ops Manager if you are configuring multiple datacenters.
- **vCenter Host:** The hostname of the vCenter that manages ESXi/vSphere.
- **vCenter Username:** A vCenter username with create and delete privileges for virtual machines (VMs) and folders.
- **vCenter Password:** The password for the vCenter user specified above.
- **Datacenter Name:** The name of the datacenter as it appears in vCenter.
- **Virtual Disk Type:** The Virtual Disk Type to provision for all VMs. For guidance about the virtual disk type to select, see [Provisioning a Virtual Disk in vSphere](#).

 **Note:** The following fields do not allow whitespace. Including whitespace characters in datastore or datastore folder names causes an error.

- **Ephemeral Datastore Names (comma delimited):** The names of the datastores that store ephemeral VM disks deployed by Ops Manager.
- **Persistent Datastore Names (comma delimited):** The names of the datastores that store persistent VM disks deployed by Ops Manager.
- **VM Folder:** The vSphere datacenter folder where Ops Manager places VMs. This defaults to `pcf_vms`.
- **Template Folder:** The vSphere datacenter folder where Ops Manager places VMs. This defaults to `pcf_templates`.
- **Disk path Folder:** The vSphere datastore folder where Ops Manager creates attached disk images. This defaults to `pcf_disk`. You must not nest this folder.

5. Select a network configuration from one of the following:

- **Standard vCenter Networking:** This is the default option when upgrading Ops Manager.
- **NSX Networking:** Select this option to enable VMware NSX Network Virtualization. Configure NSX networking by entering the following information:
 - **NSX Mode:** Select either **NSX-V** or **NSX-T**.

 **Note:** If you want to configure NSX Networking for PKS, you must select **NSX-T**. For more information about NSX Networking for PKS, see the [Configure vCenter for PKS](#) section of *Configuring BOSH Director with NSX-T for PKS*.

- **NSX Address:** The address of the NSX manager.
- **NSX Username:** The username to connect to the NSX manager.
- **NSX Password:** The password for the username specified above.
- **NSX CA Cert:** A CA certificate in PEM format that authenticates to the NSX server. If the NSX Manager generated a self-signed certificate, use the following command to retrieve the CA certificate using OpenSSL:

```
openssl s_client -showcerts -connect NSX-MANAGER-ADDRESS:443 < /dev/null 2> /dev/null | openssl x509
```

Where `NSX-MANAGER-ADDRESS` is the address of the NSX manager.

6. Click **Save**.

 **Note:** After your initial deployment, you cannot edit the VM Folder, Template Folder, and Disk path Folder names.

7. (Optional) Click **Add vCenter Config** toward the top of the form to configure additional vCenters. Once you click **Save**, your multiple vCenter Configs are listed in the **vCenter Configs** pane. For more information about multiple vCenter configs, see [Managing Multiple Data Centers](#).

Step 3: Director Config Page

1. Select **Director Config**.

Director Config

NTP Servers (comma delimited)*

JMX Provider IP Address

Bosh HM Forwarder IP Address

☐ Enable VM Resurrecter Plugin

☐ Enable Post Deploy Scripts

☐ Recreate all VMs

This will force BOSH to recreate all VMs on the next deploy. Persistent disk will be preserved

☐ Enable bosh deploy retries

This will attempt to re-deploy a failed deployment up to 5 times.

☐ Keep Unreachable Director VMs

- In the **NTP Servers (comma delimited)** field, enter your NTP server addresses.

 **Note:** The NTP server configuration only updates after VM recreation. Ensure that you select the **Recreate all VMs** checkbox if you modify the value of this field.

- Leave the **JMX Provider IP Address** field blank.

 **Note:** Starting in PCF v2.0, BOSH-reported component metrics are available in the Loggregator Firehose by default. If you continue to use PCF JMX Bridge to consume these component metrics outside of the Firehose, you may receive duplicate data. To prevent this, leave the **JMX Provider IP Address** field blank. For additional guidance, see [BOSH System Metrics Available in Loggregator Firehose](#) in the PCF v2.0 Release Notes.

- Leave the **Bosh HM Forwarder IP Address** field blank.

 **Note:** Starting in PCF v2.0, BOSH-reported component metrics are available in the Loggregator Firehose by default. If you continue to use the BOSH HM Forwarder to consume these component metrics, you may receive duplicate data. To prevent this, leave the **Bosh HM Forwarder IP Address** field blank. For additional guidance, see [BOSH System Metrics Available in Loggregator Firehose](#) in the PCF v2.0 Release Notes.

- Select the **Enable VM Resurrecter Plugin** to enable Ops Manager Resurrector functionality and increase your runtime availability. If you intend to install PAS, see [Using BOSH Resurrector and vSphere HA](#) for more information about the Resurrector plugin.
- Select **Enable Post Deploy Scripts** to run a post-deploy script after deployment. This script allows the job to execute additional commands against a deployment.

 **Note:** You must enable post-deploy scripts to install PKS.

- Select **Recreate all VMs** to force BOSH to recreate all VMs on the next deploy. This process does not destroy any persistent disk data.
- Select **Enable bosh deploy retries** to instruct Ops Manager to retry failed BOSH operations up to five times.
- (Optional) Disable **Allow Legacy Agents** if all of your tiles have stemcells v3468 or later. Disabling the field will allow Ops Manager to implement TLS secure communications.

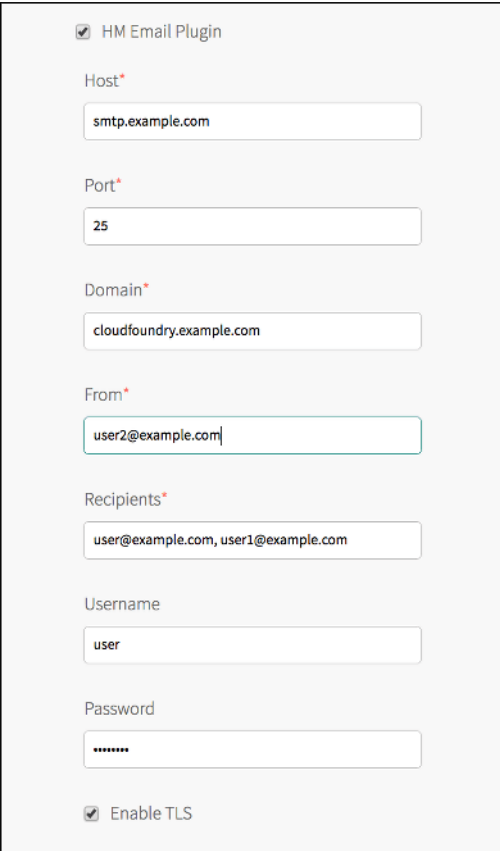

10. Select **Keep Unreachable Director VMs** if you want to preserve BOSH Director VMs after a failed deployment for troubleshooting purposes.

☒ HM Pager Duty Plugin
 Service Key*
 YOUR-PAGERDUTY-SERVICE-KEY
 HTTP Proxy
 YOUR-HTTP-PROXY

11. Select **HM Pager Duty Plugin** to enable Health Monitor integration with PagerDuty.

- **Service Key:** Enter your API service key from PagerDuty.
- **HTTP Proxy:** Enter an HTTP proxy for use with PagerDuty.

☒ HM Email Plugin
 Host*
 smtp.example.com
 Port*
 25
 Domain*
 cloudfoundry.example.com

 user
 Password

☒ Enable TLS

12. Select **HM Email Plugin** to enable Health Monitor integration with email.

- **Host:** Enter your email hostname.
- **Port:** Enter your email port number.
- **Domain:** Enter your domain.
- **From:** Enter the address for the sender.
- **Recipients:** Enter comma-separated addresses of intended recipients.
- **Username:** Enter the username for your email server.
- **Password:** Enter the password for your email server.
- **Enable TLS:** Select this checkbox to enable Transport Layer Security.

13. For **CredHub Encryption Provider**, you can choose whether BOSH CredHub stores its encryption key internally on the BOSH Director and CredHub VM, or in an external hardware security module (HSM). The HSM option is more secure.

Before configuring an HSM encryption provider in the **Director Config** pane, you must follow the procedures and collect information described in [Preparing CredHub HSMs for Configuration](#).

Note: After you deploy Ops Manager with an HSM encryption provider, you cannot change BOSH CredHub to store encryption keys internally.

CredHub Encryption Provider

☒ Internal
 ☐ Luna HSM

Encryption Key Name*

Provider Partition*

Provider Partition Password*

Provider Client Certificate*

Provider Client Certificate Private Key*

HSM Host Address*

HSM Port Address*

Partition Serial Number*

HSM Certificate*

- **Internal:** Select this option for internal CredHub key storage. This option is selected by default and requires no additional configuration.
- **Luna HSM:** Select this option to use a SafeNet Luna HSM as your permanent CredHub encryption provider, and fill in the following fields:
 1. **Encryption Key Name:** Any name to identify the key that the HSM uses to encrypt and decrypt the CredHub data. Changing this key name after you deploy Ops Manager can cause service downtime.
 2. **Provider Partition:** The partition that stores your encryption key. Changing this partition after you deploy Ops Manager could cause service downtime. For this value and the ones below, use values gathered in [Preparing CredHub HSMs for Configuration](#).
 3. **Provider Partition Password**
 4. **Provider Client Certificate:** The certificate that validates the identity of the HSM when CredHub connects as a client.
 5. **Provider Client Certificate Private Key**
 6. **HSM Host Address**
 7. **HSM Port Address:** If you do not know your port address, enter `1792`.
 8. **Partition Serial Number**
 9. **HSM Certificate:** The certificate that the HSM presents to CredHub to establish a two-way mTLS connection.

14. Select a **Blobstore Location** to either configure the blobstore as an internal server or an external endpoint. Because the internal server is unscalable and less secure, Pivotal recommends that you configure an external blobstore.

 **Note:** After you deploy Ops Manager, you cannot change the blobstore location.

Blobstore Location

☒ Internal
☐ S3 Compatible Blobstore

S3 Endpoint*

Bucket Name*

Access Key*

Secret Key*

☒ V2 Signature
☐ V4 Signature

Region*

☐ GCS Blobstore

Bucket Name*

Storage Class*

Regional

Service Account Key*

- o **Internal:** Select this option to use an internal blobstore. Ops Manager creates a new VM for blob storage. No additional configuration is required.
- o **S3 Compatible Blobstore:** Select this option to use an external S3-compatible endpoint. Follow the procedures in [Sign up for Amazon S3](#) and [Creating a Bucket](#) in the AWS documentation. When you have created an S3 bucket, complete the following steps:
 1. **S3 Endpoint:** Navigate to the [Regions and Endpoints](#) topic in the AWS documentation.
 - a. Locate the endpoint for your region in the **Amazon Simple Storage Service (S3)** table and construct a URL using your region's endpoint. For example, if you are using the `us-west-2` region, the URL you create would be `https://s3-us-west-2.amazonaws.com`. Enter this URL into the **S3 Endpoint** field.
 - b. On a command line, run `ssh ubuntu@OPS-MANAGER-FQDN` to SSH into the Ops Manager VM. Replace `OPS-MANAGER-FQDN` with the fully qualified domain name of Ops Manager.
 - c. Copy the custom public CA certificate you used to sign the S3 endpoint into `/etc/ssl/certs` on the Ops Manager VM.
 - d. On the Ops Manager VM, run `sudo update-ca-certificates -f -v` to import the custom CA certificate into the Ops Manager VM truststore.

 **Note:** You must also add this custom CA certificate into the **Trusted Certificates** field in the **Security** page. See [Security Page](#) for instructions.

2. **Bucket Name:** Enter the name of the S3 bucket.
3. **Access Key** and **Secret Key:** Enter the keys you generated when creating your S3 bucket.
4. Select **V2 Signature** or **V4 Signature**. If you select **V4 Signature**, enter your **Region**.

 **Note:** AWS recommends using Signature Version 4. For more information about AWS S3 Signatures, see [Authenticating Requests](#) in the AWS documentation.

- **Enable TLS:** Select this checkbox to enable TLS.

 **Note:** If you are using Linux stemcells, make sure you have configured [Linux stemcell v3586.16 or later](#) for all tiles before enabling TLS.

 **Note:** If you are using PAS for Windows 2016, make sure you have configured [Windows stemcell v1709.10 or later](#) for all tiles before enabling TLS.

- **GCS Blobstore:** Select this option to use an external GCS endpoint. To create a GCS bucket, you must have a GCS account. Follow the procedures in [Creating Storage Buckets](#) in the GCS documentation to create a GCS bucket. When you have created a GCS bucket, complete the following steps:
 1. **Bucket Name:** Enter the name of your GCS bucket.
 2. **Storage Class:** Select the storage class for your GCS bucket. See [Storage Classes](#) in the GCP documentation for more information.
 3. **Service Account Key:** Follow the steps in the [Set up an IAM Service Account](#) section of *Preparing to Deploy Ops Manager on GCP Manually* to download a JSON file with a private key. Enter the contents of the JSON file into the field.

15. Select a **Database Location**. By default, Ops Manager deploys and manages an **Internal** database for you. If you choose to use an **External MySQL Database**, complete the associated fields with information obtained from your external MySQL Database provider: **Host**, **Port**, **Username**,

Database Location

☒ Internal

☐ External MySQL Database

Host*

Port*

Username*

Password*

Database*

Password, and Database.

In addition, if you

selected the **Enable TLS for Director Database** checkbox, you can complete the following optional fields:

- **Enable TLS:** Select this checkbox enables TLS communication between the BOSH Director and the database.
- **TLS CA:** Enter the Certificate Authority for the TLS Certificate.
- **TLS Certificate:** Enter the client certificate for mutual TLS connections to the database.
- **TLS Private Key:** Enter the client private key for mutual TLS connections to the database.
- **Advanced DB Connection Options:** If you would like to provide additional options for the database, use this field to provide a JSON-formatted options string.

16. (Optional) **Director Workers:** Set the number of workers available to execute Director tasks. This field defaults to [5](#).

17. (Optional) **Max Threads:** Enter the number of operations the BOSH Director can perform simultaneously. For vSphere, the default value is [32](#). Leave the field blank to use this default value. Pivotal recommends that you use the default value unless doing so results in rate limiting or errors on your IaaS.

18. (Optional) **Director Hostname:** Enter a valid hostname to add a custom URL for your BOSH Director. You can also use this field to configure a load

balancer in front of your BOSH Director. For more information, see [How to Set Up a Load Balancer in Front of Operations Manager Director](#) in the Pivotal Support documentation.

⚠ warning: In Ops Manager v2.2.7 and earlier, if you change the **Director Hostname** after your initial deployment, VMs become unavailable. This causes PCF downtime. To restore VM availability, enable **Recreate All VMs** and redeploy. This issue is resolved in [Ops Manager v2.2.8](#) and later.

19. (Optional) Enter your list of comma-separated **Excluded Recursors** to declare which IP addresses and ports should not be used by the DNS server.
20. (Optional) To disable BOSH DNS, select the **Disable BOSH DNS server for troubleshooting purposes** checkbox. For more information about the BOSH DNS service discovery mechanism, see [BOSH DNS Enabled by Default](#) in the Ops Manager v2.2 Release Notes.

⚡ Breaking Change: Do not disable BOSH DNS without consulting Pivotal Support.

💡 Note: If you plan to deploy PKS, do not disable BOSH DNS. If PAS and PKS run on the same instance of Ops Manager, you cannot use the opt-out feature of BOSH DNS for your PAS without breaking PKS. To opt out of BOSH DNS in your PAS deployment, install the tile on a separate instance of Ops Manager.

21. (Optional) **Custom SSH Banner:** Enter text to set a custom banner that users see when logging in to the Director using SSH.

☐ Disable BOSH DNS server for troubleshooting purposes

Custom SSH Banner

22. (Optional) Enter your comma-separated custom **Identification Tags**. For example, `iaas:foundation1, hello:world`. You can use the tags to identify your foundation when viewing VMs or disks from your IaaS.
23. Click **Save**.

💡 Note: After your initial deployment, you cannot edit the Blobstore and Database locations.

Step 4: Create Availability Zones Page

An Ops Manager availability zone (AZ) corresponds to your vCenter clusters and resource pools.

Multiple AZs allow you to provide high-availability and load balancing to your applications. When you run more than one instance of an application, Ops Manager balances those instances across all of the AZs assigned to the application.

Pivotal recommends that you use at least three AZs for a highly available installation of your chosen runtime.

1. Select **Create Availability Zones** to navigate to the pane.

Create Availability Zones

Availability Zones

Clusters and resource pools to which you will deploy Pivotal products

Add

▶ second-az

Save

2. Use the following steps to create one or more AZs for your applications to use:

- Click **Add**.
- Enter a unique **Name** for the AZ.
- Select a vCenter config name from the **IaaS Configuration** dropdown to associate your AZ with a vCenter. If you have only one vCenter config or if you are creating your first AZ, **IaaS Configuration** defaults to the first vCenter and cannot be configured.
- Enter the name of an existing vCenter **Cluster** to use as an AZ.
- **(Optional)** Enter the name of a **Resource Pool** in the vCenter cluster that you specified above. The jobs running in this AZ share the CPU and memory resources defined by the pool.
- **(Optional)** Click **Add Cluster** to create another set of **Cluster** and **Resource Pool** fields. You can add multiple clusters. Click the trash icon to delete a cluster. The first cluster cannot be deleted.

 **Note:** For the PAS runtime, see [Availability Zones in vSphere](#) for additional information.

3. Click **Save**.

Step 5: Create Networks Page

1. Select **Create Networks**.

Create Networks

Warning: Pivotal recommends keeping the IP settings throughout the life of your installation. Ops Manager may prevent you from changing them in the future. Contact Pivotal support for help completing such a change.

Availability Zones*

☒ default*

Add Network

Add Subnet

2. Select **Enable ICMP checks** to enable ICMP on your networks. Ops Manager uses ICMP checks to confirm that components within your network are reachable.

3. Depending on the runtime that you are deploying, do one of the following:

a. For PAS, use the following steps to create one or more Ops Manager networks:

- Click **Add Network**.
- Enter a unique **Name** for the network.
- Click **Add Subnet** to create one or more subnets for the network.
- Enter the full path and **vSphere Network Name** as it displays in vCenter. For example, enter `YOUR-DIRECTORY-NAME/YOUR-NETWORK-NAME`. If your vSphere Network Name contains a forward slash character, replace the forward slash with the URL-encoded forward slash character `%2F`.
- For **CIDR**, enter a valid CIDR block in which to deploy VMs. For example, enter `192.0.2.0/24`.
- For **Reserved IP Ranges**, enter any IP addresses from the **CIDR** that you want to blacklist from the installation. Ops Manager will not deploy VMs to any address in this range.
- Enter your **DNS** and **Gateway** IP addresses.
- Select which **Availability Zones** to use with the network.

b. For PKS, create the following Ops Manager networks:

- `infrastructure`: This network is for Ops Manager, the BOSH Director, the PKS broker, and the PKS API.
- `pkcs`: If you have a large deployment with multiple tiles, you can choose to deploy the PKS broker and PKS API to a separate network

© Copyright Pivotal Software Inc, 2013-2019

767

2.2

named `main`. See the table below for more information.

- `services`: Network for creating the master and worker VMs for Kubernetes clusters. The CIDR should not conflict with the pod overlay network `10.200.0.0/16` or the reserved Kubernetes services CIDR of `10.100.200.0/24`.

Use the values from the following table as a guide when you create each network, replacing the IP addresses with ranges that are available in your vSphere environment:

| Infrastructure Network | Field | Configuration |
|-------------------------|----------------------|---|
| | Name | <code>infrastructure</code> |
| | vSphere Network Name | <code>pcf-virt-net/pcf-infrastructure-subnet</code> |
| | CIDR | <code>192.168.101.0/26</code> |
| | Reserved IP Ranges | <code>192.168.101.1–192.168.101.9</code> |
| | DNS | <code>192.168.101.2</code> |
| | Gateway | <code>192.168.101.1</code> |
| Main Network (Optional) | Field | Configuration |
| | Name | <code>pks</code> |
| | vSphere Network Name | <code>pcf-virt-net/pcf-pks-subnet</code> |
| | CIDR | <code>192.168.16.0/26</code> |
| | Reserved IP Ranges | <code>192.168.16.1–192.168.16.9</code> |
| | DNS | <code>192.168.16.2</code> |
| | Gateway | <code>192.168.16.1</code> |
| Service Network | Field | Configuration |
| | Name | <code>services</code> |
| | vSphere Network Name | <code>pcf-virt-net/pcf-services-subnet</code> |
| | CIDR | <code>192.168.20.0/22</code> |
| | Reserved IP Ranges | <code>192.168.20.1–192.168.20.9</code> |
| | DNS | <code>192.168.20.2</code> |
| | Gateway | <code>192.168.20.1</code> |

4. Click **Save**.

 **Note:** Multiple networks allow you to place vCenter on a private network and the rest of your deployment on a public network. Isolating vCenter in this manner denies access to it from outside sources and reduces possible security vulnerabilities.

 **Note:** If you use the Cisco Nexus 1000v Switch, see to [Using the Cisco Nexus 1000v Switch with Ops Manager](#) for more information.

 **Note:** After you deploy Ops Manager, you add subnets with overlapping Availability Zones to expand your network. For more information about configuring additional subnets, see [Expanding Your Network with Additional Subnets](#).

Step 6: Assign AZs and Networks Page

1. Select **Assign AZs and Networks**.

Assign AZs and Networks

The BOSH Director is a single instance.

Choose the availability zone in which to place that instance. It is highly recommended that you backup this VM on a regular basis to preserve settings.

Singleton Availability Zone

AZ-MGMT

Network

infrastructure

Save

2. Use the dropdown to select a **Singleton Availability Zone**. The BOSH Director installs in this Availability Zone.
3. Use the dropdown to select a **Network** for your BOSH Director.
4. Click **Save**.

Step 7: Security Page

Security

Trusted Certificates

-----BEGIN CERTIFICATE-----

THE

-----END CERTIFICATE-----

These certificates enable BOSH-deployed components to trust a custom root certificate.

Generate VM passwords or use single password for all VMs

☒ Generate passwords
 ☐ Use default BOSH password

Save

1. Select **Security**.
2. In **Trusted Certificates**, enter your custom certificate authority (CA) certificates to insert into your organization's certificate trust chain. This feature enables all BOSH-deployed components in your deployment to trust custom root certificates.

To enter multiple certificates, paste your certificates one after the other. For example, format your certificates like the following:

```
-----BEGIN CERTIFICATE-----
ABCDEF12345678ABCDEF12345678ABCDEF12345678AB
EFGH12345678ABCDEF12345678ABCDEF12345678ABCDEF
GH12345678ABCDEF12345678ABCDEF12345678...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
BCDEF12345678ABCDEF12345678ABCDEF12345678ABB
EFGH12345678ABCDEF12345678ABCDEF12345678ABCDEF
GH12345678ABCDEF12345678ABCDEF12345678...
```

```
-----END CERTIFICATE-----  
-----BEGIN CERTIFICATE-----  
CDEFGH12345678ABCDEFGH12345678ABCDEFGH12345678ABBB  
EFGH12345678ABCDEFGH12345678ABCDEFGH12345678ABCDEF  
GH12345678ABCDEFGH12345678ABCDEFGH12345678...  
-----END CERTIFICATE-----
```

 **Note:** If you want to use Docker Registries for running app instances in Docker containers, enter the certificate for your private Docker Registry in this field. See [Using Docker Registries](#)  for more information on running app instances in PAS using Docker Registries.

3. Choose **Generate passwords** or **Use default BOSH password**. Pivotal recommends that you use the **Generate passwords** option for greater security.
4. Click **Save**. To view your saved Director password, click the **Credentials** tab.

Step 8: Syslog Page

 **Note:** BOSH Director logs contain sensitive information that should be considered privileged. For example, these logs may contain cloud provider credentials. If you choose to forward logs to an external syslog endpoint, use TLS encryption to prevent information from being intercepted by a third party.

1. Select **Syslog**.

Syslog

Do you want to configure Syslog for Bosh Director?

☐ No
 ☒ Yes

Address*

The address or host for the syslog server

Port*

Transport Protocol*

TCP

☐ Enable TLS

Permitted Peer*

SSL Certificate*

Save

- (Optional) Select **Yes** to send BOSH Director system logs to a remote server.
- In the **Address** field, enter the IP address or DNS name for the remote server.
- In the **Port** field, enter the port number that the remote server listens on.
- In the **Transport Protocol** dropdown menu, select **TCP**, **UDP**, or **REL**. This selection determines which transport protocol is used to send the logs to the remote server.
- (Optional) Pivotal strongly recommends that you enable TLS encryption when forwarding logs as they may contain sensitive information. For example, these logs may contain cloud provider credentials. To enable TLS, perform the following steps.
 - In the **Permitted Peer** field, enter either the name or SHA1 fingerprint of the remote peer.
 - In the **SSL Certificate** field, enter the SSL certificate for the remote server.
- Click **Save**.

Step 9: Resource Config Page

- Select **Resource Config**.

Resource Config

| JOB | INSTANCES | PERSISTENT DISK TYPE | VM TYPE |
|------------------------|--------------|----------------------|---|
| Ops Manager Director | Automatic: 1 | Automatic: 50 GB | Automatic: medium.disk (cpu: 2, ram: 4 GB |
| Master Compilation Job | Automatic: 4 | None | Automatic: large.cpu (cpu: 4, ram: 4 GB, di |

Save

- Adjust any values as necessary for your deployment. Under the **Instances**, **Persistent Disk Type**, and **VM Type** fields, choose **Automatic** from the dropdown to allocate the recommended resources for the job. If the **Persistent Disk Type** field reads **None**, the job does not require persistent disk space.

 **Note:** Ops Manager requires a Director VM with at least 8 GB memory.

 **Note:** If you set a field to **Automatic** and the recommended resource allocation changes in a future version, Ops Manager automatically uses the updated recommended allocation.

 **Note:** If you install PAS for Windows, provision your **Master Compilation Job** with at least 128 GB of disk space.

- Click **Save**.

Step 10: (Optional) Add Custom VM Extensions

Use the Ops Manager API to add custom properties to your VMs such as associated security groups and load balancers. For more information, see [Managing Custom VM Extensions](#).

Step 11: Complete the BOSH Director Installation

- Click the **Installation Dashboard** link to return to the Installation Dashboard.
- Click **Apply Changes** on the right navigation.

Next Steps

After you complete this procedure, follow the instructions for the runtime that you intend to install.

- To install PAS, see [Deploying PAS on vSphere](#).
- To install PKS, see [Installing PKS on vSphere](#).

For more information about PCF runtimes, see [Installing Runtimes](#).

Deploying PAS on vSphere

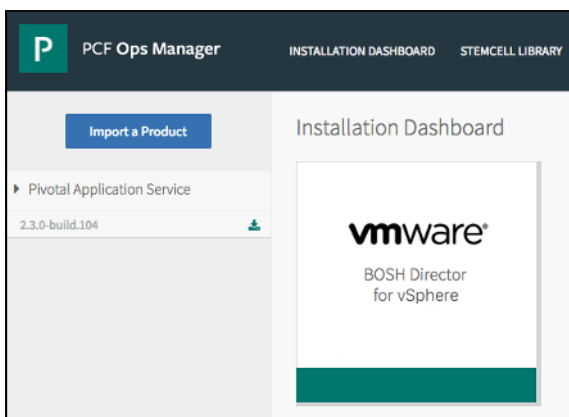

Page last updated:

This topic describes how to configure the Pivotal Application Service (PAS) components that you need to run [Pivotal Cloud Foundry](#) (PCF) for VMware vSphere.

Note: If you plan to install the IPsec add-on, you must do so before installing any other tiles. For more information, see [Installing the IPsec Add-on for PCF](#).

Step 1: Add PAS to Ops Manager

1. Log in to [Pivotal Network](#) and download PAS.
2. From the **Releases** dropdown, select the release you want to install and choose one of the following:
 - Click PAS to download the PAS `.pivotal` file.
 - Click PCF Small Footprint PAS to download the Small Footprint Runtime `.pivotal` file. For more information, see [Getting Started with Small Footprint Runtime](#).
3. Click **Import a Product**. Select the PAS `.pivotal` file that you downloaded from Pivotal Network and click **Open**. After the import completes, PAS appears as an available product.
4. Hover over PAS and click **Add**.

5. Click the PAS tile in the Installation Dashboard.

Step 2: Assign Availability Zones and Networks

1. Select **Assign AZs and Networks**. These are the Availability Zones that you create when configuring BOSH Director. For more information, see [Create Availability Zone Page](#) in *Configuring BOSH Director on vSphere*.
2. **(vSphere Only):** Under **Place singleton jobs**, select an Availability Zone. Ops Manager runs any job with a single instance in this Availability Zone.
3. **(vSphere Only):** Under **Balance other jobs**, select one or more Availability Zones. Ops Manager balances instances of jobs with more than one instance across the Availability Zones that you specify.

- From the **Network** dropdown, choose the network where you want to run PAS.

The screenshot shows the 'Pivotal Application Service' settings interface. At the top, there's a navigation bar with 'Settings', 'Status', 'Credentials', and 'Logs'. Below this, a sidebar on the left lists various configuration categories, each with a green checkmark: 'Assign AZs and Networks' (highlighted), 'Domains', 'Networking', 'Application Containers', 'Application Developer Controls', 'Application Security Groups', 'Authentication and Enterprise SSO', and 'Databases'. The main content area is titled 'AZ and Network Assignments'. It contains two sections: 'Place singleton jobs in' with a radio button selected for 'first-az', and 'Balance other jobs in' with a checkbox selected for 'first-az'. Below these is a 'Network' dropdown menu currently showing 'first-network'. A blue 'Save' button is positioned at the bottom right of the configuration area.

- Click **Save**.

Note: When you save this form, a verification error displays because the PCF security group blocks ICMP. You can ignore this error.

Step 3: Configure Domains

- Select **Domains**.

The screenshot shows the 'Domains' configuration page. At the top, a text block explains: 'Application Service hosts applications at subdomains under its apps domain and assigns system components to subdomains under its system domain. You need to configure a wildcard DNS for both the apps domain and system domain. The two domains can be the same, although this is not recommended.' Below this, there are two input fields: 'System Domain' and 'Apps Domain'. Both fields contain the text 'sys.metallicseaweed.cf-app.com'. A blue 'Save' button is located at the bottom left of the form.

- Enter the system and application domains.
 - The **System Domain** defines your target when you push apps to PAS.
 - The **Apps Domain** defines where PAS should serve your apps.

Note: Pivotal recommends that you use the same domain name but different subdomain names for your system and app domains.

Doing so allows you to use a single wildcard certificate for the domain while preventing apps from creating routes that overlap with system routes. For example, name your system domain `system.EXAMPLE.com` and your apps domain `apps.EXAMPLE.com`.

3. Click **Save**.

Step 4: Configure Networking

1. Select **Networking**.
2. The values you enter in the **Router IPs** and **HAProxy IPs** fields depend on whether you are using HAProxy in your deployment. Use the table below to determine how to complete these fields.

Note: If you choose to assign specific IP addresses in either the **Router IPs** or **HAProxy IPs** field, ensure that these IP addresses are in the subnet that you configured for PAS in Ops Manager.

| Using HAProxy? | Router IPs Field | HAProxy IPs Field |
|----------------|--|--|
| No | <ol style="list-style-type: none"> 1. Choose IP addresses from the subnet you configured in Ops Manager. 2. Enter these IP addresses in the Router IPs field. You should specify more than one IP address for high availability. 3. Configure your load balancer to forward requests for the domains that you have configured for your deployment to these IP addresses. | Leave this field blank. |
| Yes | Leave this field blank. | <ol style="list-style-type: none"> 1. Choose IP addresses from the subnet you configured in Ops Manager. 2. Enter these IP addresses in the HAProxy IPs field. You should specify more than one IP address for high availability. 3. Configure your load balancer to forward requests for the domains you have configured for your deployment to these IP addresses. |

3. (Optional) In **SSH Proxy IPs**, add the IP address for your Diego Brain, which will accept requests to SSH into application containers on port `2222`.
4. (Optional) In **TCP Router IPs**, add the IP addresses you want assigned to the TCP Routers. You enable this feature at the bottom of this screen.

Configure security and routing services for your platform. It is usually preferable to use your own load balancer instead of an HAProxy instance as your point-of-entry to the platform.

Router IPs

10.85.10.200

SSH Proxy IPs

10.85.10.201

HAProxy IPs

TCP Router IPs

5. Under **Certificates and Private Key for HAProxy and Router**, you must provide at least one **Certificate** and **Private Key** name and certificate keypair for HAProxy and Gorouter. The HAProxy and Gorouter are enabled to receive TLS communication by default. You can configure multiple certificates for HAProxy and Gorouter.

- a. Click the **Add** button to add a name for the certificate chain and its private keypair. This certificate is the default used by Gorouter and HAProxy.

Certificates and Private Keys for HAProxy and Router

Add

▼ example-cert

Name *

example-cert

A human-readable name describing the use of this certificate.

Certificate and Private Key for HAProxy and Router *

-----BEGIN CERTIFICATE-----

MIIE...

-----END CERTIFICATE-----

-----BEGIN RSA PRIVATE KEY-----

MIIE...

-----END RSA PRIVATE KEY-----

Generate RSA Certificate

▼ example-cert-2

Name *

example-cert-2

Certificate and Private Key for HAProxy and Router *

-----BEGIN CERTIFICATE-----

MIIE...

-----END CERTIFICATE-----

-----BEGIN RSA PRIVATE KEY-----

MIIE...

-----END RSA PRIVATE KEY-----

You can either provide a certificate signed by a Certificate Authority (CA) or click on the **Generate RSA Certificate** link to generate a self-signed certificate in Ops Manager.

- b. If you want to configure multiple certificates for HAProxy and Gorouter, click the **Add** button and fill in the appropriate fields for each additional certificate keypair.

For details about generating certificates in Ops Manager for your wildcard system domains, see the [Providing a Certificate for Your SSL/TLS Termination Point](#) topic.

Note: If you configured Ops Manager Front End without a certificate, you can use this new certificate to complete Ops Manager configuration. To configure your Ops Manager Front End certificate, see *Configure Front End* in [Preparing to Deploy Ops Manager on GCP Manually](#).

Note: Ensure that you add any certificates that you generate in this pane to your infrastructure load balancer.

6. (Optional) When validating client requests using mutual TLS, the Gorouter trusts multiple certificate authorities (CAs) by default. If you want to configure the Gorouter and HAProxy to trust additional CAs, enter your CA certificates under **Certificate Authorities Trusted by Router and HAProxy**. All CA certificates should be appended together into a single collection of PEM-encoded entries.

Certificate Authorities Trusted by Router and HAProxy

In addition to well-known, public CAs, and those trusted via the BOSH trusted certificates collection, these certificates can be used to validate the certificates from incoming client requests. All CA certificates should be appended together into a single collection of PEM-encoded entries.

- In the **Minimum version of TLS supported by HAProxy and Router** field, select the minimum version of TLS to use in HAProxy and Gorouter communications. HAProxy and Gorouter use TLS v1.2 by default. If you need to accommodate clients that use an older version of TLS, select a lower minimum version. For a list of TLS ciphers supported by the Gorouter, see [Securing Traffic into Cloud Foundry](#).

Minimum version of TLS supported by HAProxy and Router*

- ☐ TLSv1.0
- ☐ TLSv1.1
- ☒ TLSv1.2

- Configure **Logging of Client IPs in CF Router**. The **Log client IPs** option is set by default. To comply with the General Data Protection Regulation (GDPR), select one of the following options to disable logging of client IP addresses:

- If your load balancer exposes its own source IP address, disable logging of the `X-Forwarded-For` HTTP header only.
- If your load balancer exposes the source IP of the originating client, disable logging of both the source IP address and the `X-Forwarded-For` HTTP header.

Logging of Client IPs in CF Router*

- ☒ Log client IPs
- ☐ Disable logging of X-Forwarded-For header only
- ☐ Disable logging of both source IP and X-Forwarded-For header

To comply with GDPR, select one of the options to disable logging of client IPs. If the source IP exposed by your load balancer is its own, choose to disable logging of XFF header only. If the source IP exposed by your load balancer is that of the downstream client, choose to disable logging of the source IP also.

- Under **Configure support for the X-Forwarded-Client-Cert header**, configure PCF handles `x-forwarded-client-cert` (XFCC) HTTP headers based on where TLS is terminated for the first time in your deployment.

Configure support for the X-Forwarded-Client-Cert header. This header can be used by applications to verify the requester via mutual TLS. The option you should select depends upon where you will be terminating the TLS connection for the first time. *

- ☒ TLS terminated for the first time at infrastructure load balancer
- ☐ TLS terminated for the first time at HAProxy
- ☐ TLS terminated for the first time at the Router

The following table

indicates which option to choose based on your deployment layout.

| If your deployment is configured as follows: | Then select the following option: | Additional notes: |
|--|--|---|
| <ul style="list-style-type: none"> The Load Balancer is terminating TLS, and Load balancer is configured to put the client certificate from a mutual authentication TLS handshake into the X-Forwarded-Client-Cert HTTP header | TLS terminated for the first time at infrastructure load balancer (default). | Both HAProxy and the Gorouter forward the XFCC header when included in the request. |
| <ul style="list-style-type: none"> The Load Balancer is configured to pass through the TLS handshake via TCP to | TLS terminated for | HAProxy sets the XFCC header with the client certificate received in the TLS handshake. The Gorouter forwards the header. |

| | | |
|--|--|---|
| <ul style="list-style-type: none"> the instances of HAProxy, and HAProxy instance count is > 0 | the first time at HAProxy. |  Breaking Change: In the Router behavior for Client Certificates field, you cannot select the Router does not request client certificates option. |
| <ul style="list-style-type: none"> The Load Balancer is configured to pass through the TLS handshake via TCP to instances of the Gorouter | TLS terminated for the first time at the Gorouter. | <p>The Gorouter strips the XFCC header if it is included in the request and forwards the client certificate received in the TLS handshake in a new XFCC header.</p> <p>If you have deployed instances of HAProxy, app traffic bypasses those instances in this configuration. If you have also configured your load balancer to route requests for ssh directly to the Diego Brain, consider reducing HAProxy instances to 0.</p>  Breaking Change: In the Router behavior for Client Certificates field, you cannot select the Router does not request client certificates option. |

For a description of the behavior of each configuration option, see [Forward Client Certificate to Applications](#).

- To configure HAProxy to handle client certificates, select one of the following options in the **HAProxy behavior for Client Certificate Validation** field.

HAProxy behavior for Client Certificate Validation*

- ☒ HAProxy does not request client certificates.
- ☐ HAProxy requests but does not require client certificates. This option is necessary if you want to enable mTLS for applications and TLS is terminated for the first time at HAProxy

- HAProxy does not request client certificates.** This option requires mutual authentication, which makes it incompatible with XFCC option **TLS terminated for the first time at HAProxy**. HAProxy does not request client certificates, so the client does not provide them and no validation occurs. This is the default configuration.
- HAProxy requests but does not require client certificates.** The HAProxy requests client certificates in TLS handshakes, validates them when presented, but does not require them.

 **warning:** Upon upgrade, PAS will fail to receive requests if your load balancer is configured to present a client certificate in the TLS handshake with HAProxy but HAProxy has not been configured with the certificate authority used to sign it. To mitigate this issue, select **HAProxy does not request client certificates** in the **Networking** pane or configure the HAProxy with the appropriate CA.

- To configure Gorouter behavior for handling client certificates, select one of the following options in the **Router behavior for Client Certificate Validation** field.

Router behavior for Client Certificate Validation*

- ☐ Router does not request client certificates. This option is incompatible with XFCC options "TLS terminated for the first time at HAProxy" and "TLS terminated for the first time at the Router" because these options require mutual authentication.
- ☒ Router requests but does not require client certificates.
- ☐ Router requires client certificates.

- Router does not request client certificates.** This option is incompatible with the XFCC configuration options **TLS terminated for the first time at HAProxy** and **TLS terminated for the first time at the Router** in PAS because these options require mutual authentication. As client certificates are not requested, client will not provide them, and thus validation of client certificates will not occur.
- Router requests but does not require client certificates.** The Gorouter requests client certificates in TLS handshakes, validates them when presented, but does not require them. This is the default configuration.
- Router requires client certificates.** The Gorouter validates that the client certificate is signed by a Certificate Authority that the Gorouter trusts. If the Gorouter cannot validate the client certificate, the TLS handshake fails.

 **warning:** Requests to the platform will fail upon upgrade if your load balancer is configured with client certificates and the Gorouter does not have the certificate authority. To mitigate this issue, select **Router does not request client certificates** for **Router behavior for Client**

Certificate Validation in the Networking pane.

- In the **TLS Cipher Suites for Router** field, review the TLS cipher suites for TLS handshakes between Gorouter and front-end clients such as load balancers or HAProxy. The default value for this field is `ECDHE-RSA-AES128-GCM-SHA256:TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384`. If you want to modify the default configuration, use an ordered, colon-delimited list of Golang-supported TLS cipher suites in the OpenSSL format. Operators should verify that the ciphers are supported by any clients or front-end components that will initiate TLS handshakes with Gorouter. For a list of TLS ciphers supported by Gorouter, see [Securing Traffic into Cloud Foundry](#).

TLS Cipher Suites for Router *

ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384

Verify that every client participating in TLS handshakes with Gorouter has at least one cipher suite in common with Gorouter.

 **Note:** Specify cipher suites that are supported by the versions configured in the **Minimum version of TLS supported by HAProxy and Router** field.

- In the **TLS Cipher Suites for HAProxy** field, review the TLS cipher suites for TLS handshakes between HAProxy and its clients such as load balancers and Gorouter. The default value for this field is the following:
`DHE-RSA-AES128-GCM-SHA256:DHE-RSA-AES256-GCM-SHA384:ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384` If you want to modify the default configuration, use an ordered, colon-delimited list of TLS cipher suites in the OpenSSL format. Operators should verify that the ciphers are supported by any clients or front-end components that will initiate TLS handshakes with HAProxy.

TLS Cipher Suites for HAProxy *

DHE-RSA-AES128-GCM-SHA256:DHE-RSA-AES256-GCM-SHA384:ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384

Verify that every client participating in TLS handshakes with HAProxy has at least one cipher suite in common with HAProxy.

 **Note:** Specify cipher suites that are supported by the versions configured in the **Minimum version of TLS supported by HAProxy and Router** field.

- Under **HAProxy forwards requests to Router over TLS**, select **Enable** or **Disable** based on your deployment layout.

HAProxy forwards requests to Router over TLS. When enabled, HAProxy will forward all requests to the Router over TLS. HAProxy will use the CA provided to verify the certificates provided by the Router. *

☒ Enable

Certificate Authority for HAProxy Backend *

You need to provide a certificate authority for the certificate and key provided in the "Certificate and Private Key for HAProxy and Router" field. HAProxy will verify those certificates using this CA when establishing a connection. If you generated that certificate and key using the "Generate RSA Certificate" feature, then your CA is the Ops Manager CA, and can be found by visiting the "/api/v0/certificate_authorities" API endpoint.

☐ Disable

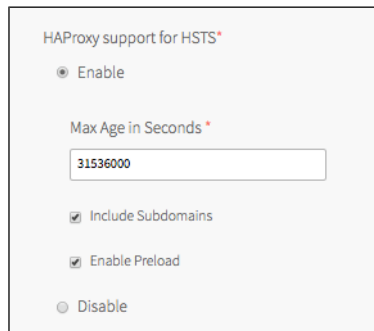

◦ Enable HAProxy forwarding of requests to Router over TLS

| If you want to: | Encrypt communication between HAProxy and the Gorouter |
|-------------------------------|---|
| Then configure the following: | <ol style="list-style-type: none"> 1. Leave Enable selected. 2. In the Certificate Authority for HAProxy Backend field, specify the Certificate Authority (CA) that signed the certificate you configured in the Certificate and Private Key for HAProxy and Router field. <div>  Note: If you used the Generate RSA Certificate link to generate a self-signed certificate, then the CA to specify is the Ops Manager CA, which you can locate at the <code>/api/v0/certificate_authorities</code> endpoint in the Ops Manager API. </div> <ol style="list-style-type: none"> 3. Make sure that Gorouter and HAProxy have TLS cipher suites in common in the TLS Cipher Suites for Router and TLS Cipher Suites for HAProxy fields. |
| See also: | <ul style="list-style-type: none"> ◦ Terminating SSL/TLS at the Load Balancer and Gorouter ◦ Providing a Certificate for Your SSL/TLS Termination Point ◦ Using the Ops Manager API |

◦ Disable HAProxy forwarding of requests to Router over TLS

| If you want to: | Use non-encrypted communication between HAProxy and Gorouter, or you are not using HAProxy |
|-------------------------------|---|
| Then configure the following: | <ol style="list-style-type: none"> 1. Select Disable. 2. If you are not using HAProxy, set the number of HAProxy job instances to <code>0</code> on the Resource Config page. See Disable Unused Resources. |
| See also: | <ul style="list-style-type: none"> ◦ Terminating SSL/TLS at the Gorouter Only ◦ Terminating SSL/TLS at the Load Balancer Only |

15. If you want to force browsers to use HTTPS when making requests to HAProxy, select **Enable** in the **HAProxy support for HSTS** field and complete

the following optional configuration steps:

- a. (Optional) **Enter a Max Age in Seconds** for the HSTS request. By default, the age is set to one year. HAProxy will force HTTPS requests from browsers for the duration of this setting.
- b. (Optional) Select the **Include Subdomains** checkbox to force browsers to use HTTPS requests for all component subdomains.
- c. (Optional) Select the **Enable Preload** checkbox to force instances of Google Chrome, Firefox, and Safari that access your HAProxy to refer to their built-in lists of known hosts that require HTTPS, of which HAProxy is one. This ensures that the first contact a browser has with your HAProxy is an HTTPS request, even if the browser has not yet received an HSTS header from HAProxy.

16. If you are not using SSL encryption or if you are using self-signed certificates, select **Disable SSL certificate verification for this environment**. Selecting this checkbox also disables SSL verification for route services.

 **Note:** For production deployments, Pivotal does not recommend disabling SSL certificate verification.

17. (Optional) If you want HAProxy or the Gorouter to reject any HTTP (non-encrypted) traffic, select the **Disable HTTP on HAProxy and Gorouter** checkbox. When selected, HAProxy and Gorouter will not listen on port 80.

☐ Disable HTTP on HAProxy and Gorouter

18. (Optional) Select the **Disable insecure cookies on the Router** checkbox to set the secure flag for cookies generated by the router.
19. (Optional) To disable the addition of Zipkin tracing headers on the Gorouter, deselect the **Enable Zipkin tracing headers on the router** checkbox. Zipkin tracing headers are enabled by default. For more information about using Zipkin trace logging headers, see [Zipkin Tracing in HTTP Headers](#).
20. (Optional) To stop the Router from writing access logs to local disk, deselect the **Enable Router to write access logs locally** checkbox. You should consider disabling this checkbox for high traffic deployments since logs may not be rotated fast enough and can fill up the disk.
21. By default, the PAS routers handle traffic for applications deployed to an isolation segment created by the PCF Isolation Segment tile. To configure the PAS routers to reject requests for applications within isolation segments, select the **Routers reject requests for Isolation Segments** checkbox.

☐ Routers reject requests for Isolation Segments

Do not enable this option without deploying

routers for each isolation segment. See the following topics for more information:

- [Installing PCF Isolation Segment](#)
- [Sharding Routers for Isolation Segments](#)

22. (Optional) By default, Gorouter support for the PROXY protocol is disabled. To enable the PROXY protocol, select **Enable support for PROXY protocol in CF Router**. When enabled, client-side load balancers that terminate TLS but do not support HTTP can pass along information from the originating client. Enabling this option may impact Gorouter performance. For more information about enabling the PROXY protocol in Gorouter, see the [HTTP Header Forwarding](#) sections in the [Securing Traffic in Cloud Foundry](#) topic.
23. In the **Choose whether to enable route services** section, choose either **Enable route services** or **Disable route services**. Route services are a class of [marketplace services](#) that perform filtering or content transformation on application requests and responses. See the [Route Services](#) topic for details.
 - a. If you enabled route services, you can also configure the **Bypass security checks for route service lookup** field. Pivotal recommends that you do not enable this field because it has potential security concerns. However, you may need to enable it if your load balancer requires mutual TLS from clients. For more information, see [Configuring Route Service Lookup](#).
24. (Optional) If you want to limit the number of app connections to the backend, enter a value in the **Max Connections Per Backend** field. You can use this field to prevent a poorly behaving app from all the connections and impacting other apps.

To choose a value for this field, review the peak concurrent connections received by instances of the most popular apps in your deployment. You can determine the number of concurrent connections for an app from the `httpStartStop` event metrics emitted for each app request.

If your deployment uses PCF Metrics, you can also obtain this peak concurrent connection information from [Network Metrics](#). The default value is

Max Connections Per Backend *

0

500

25. Under **Enable Keepalive Connections for Router**, select **Enable** or **Disable**. Keepalive connections are enabled by default. For more information, see [Keepalive Connections](#) in *HTTP Routing*.

Enable Keepalive Connections for Router*

☒ Enable
 ☐ Disable

26. (Optional) To accommodate larger uploads over connections with high latency, increase the number of seconds in the **Router Timeout to Backends** field.
27. (Optional) Use the **Frontend Idle Timeout for Gorouter and HAProxy** field to help prevent connections from your load balancer to Gorouter or HAProxy from being closed prematurely. The value you enter sets the duration, in seconds, that Gorouter or HAProxy maintains an idle open connection from a load balancer that supports keep-alive.

In general, set the value higher than your load balancer's backend idle timeout to avoid the race condition where the load balancer sends a request before it discovers that Gorouter or HAProxy has closed the connection.

See the following table for specific guidance and exceptions to this rule:

| IaaS | Guidance |
|-------|---|
| AWS | AWS ELB has a default timeout of 60 seconds, so Pivotal recommends a value greater than <code>60</code> . |
| Azure | By default, Azure load balancer times out at 240 seconds without sending a TCP RST to clients, so as an exception, Pivotal recommends a value lower than <code>240</code> to force the load balancer to send the TCP RST. |
| GCP | GCP has a default timeout of 600 seconds. For GCP HTTP load balancers, Pivotal recommends a value greater than <code>600</code> . For GCP TCP load balancers, Pivotal recommends a value less than <code>600</code> to force the load balancer to send a TCP RST. |
| Other | Set the timeout value to be greater than that of the load balancer's backend idle timeout. |

 **Note:** Do not set a frontend idle timeout lower than six seconds.

28. (Optional) Increase the value of **Load Balancer Unhealthy Threshold** to specify the amount of time, in seconds, that the router continues to accept connections before shutting down. During this period, healthchecks may report the router as unhealthy, which causes load balancers to failover to other routers. Set this value to an amount greater than or equal to the maximum time it takes your load balancer to consider a router instance unhealthy, given contiguous failed healthchecks.
29. (Optional) Modify the value of **Load Balancer Healthy Threshold**. This field specifies the amount of time, in seconds, to wait until declaring the Router instance started. This allows an external load balancer time to register the Router instance as healthy.

Load Balancer Unhealthy Threshold *

20

Load Balancer Healthy Threshold *

20

30. (Optional) If app developers in your organization want certain HTTP headers to appear in their app logs with information from the Gorouter, specify them in the **HTTP Headers to Log** field. For example, to support app developers that deploy Spring apps to PCF, you can enter [Spring-specific HTTP headers](#).

HTTP Headers to Log

31. If you expect requests larger than the default maximum of 16 Kbytes, enter a new value (in bytes) for **HAProxy Request Max Buffer Size**. You may need to do this, for example, to support apps that embed a large cookie or query string values in headers.

32. If your PCF deployment uses HAProxy and you want it to receive traffic only from specific sources, use the following fields:

- **HAProxy Protected Domains:** Enter a comma-separated list of domains to protect from unknown source requests.
- **HAProxy Trusted CIDRs:** Optionally, enter a space-separated list of CIDRs to limit which IP addresses from the **Protected Domains** can send traffic to PCF.

HAProxy Protected Domains

A comma-separated list of domains to protect from requests from unknown sources. Use this property in conjunction with "Trusted CIDRs" to protect these domains from requests from unknown sources.

HAProxy Trusted CIDRs

33. The **Loggregator Port** defaults to **443** if left blank. Enter a new value to override the default.

34. For **Container Network Interface Plugin**, select one of the following:

- **Silk:** This option is the default Container Network Interface (CNI) for PAS.
- **External:** Select this if you are deploying the [VMware NSX-T Container Plug-in for PCF](#).
 - If you select **External**, follow the instructions in [Deploying PAS with NSX-T Networking](#) in addition to the PAS configuration instructions in this topic.

⚠ warning: The NSX-T integration only works for fresh installs of PCF. If your PAS is already deployed and running with Silk as its CNI, you cannot change the CNI plugin to NSX-T.

35. If you selected **Silk** in the previous step, review the following fields:

- (Optional) You can change the value in the **Applications Network Maximum Transmission Unit (MTU)** field. Pivotal recommends setting the MTU value for your application network to **1454**. Some configurations, such as networks that use GRE tunnels, may require a smaller MTU value.
- (Optional) Enter an IP range for the overlay network in the **Overlay Subnet** box. If you do not set a custom range, Ops Manager uses **10.255.0.0/16**.

⚠ warning: The overlay network IP range must not conflict with any other IP addresses in your network.

- Enter a UDP port number in the **VXLAN Tunnel Endpoint Port** box. If you do not set a custom port, Ops Manager uses 4789.
- For **Denied logging interval**, set the per-second rate limit for packets blocked by either a container-specific [networking policy](#) or by [Application Security Group](#) rules applied across the space, org, or deployment. This field defaults to **1**.
- For **UDP logging interval**, set the per-second rate limit for UDP packets sent and received. This field defaults to **100**.
- To enable logging for app traffic, select **Log traffic for all accepted/denied application packets**. See [Manage Logging for Container-to-Container Networking](#) for more information.
- By default, containers use the same DNS servers as the host. If you want to override the DNS servers to be used in containers, enter a comma-separated list of servers in **DNS Servers**.

💡 Note: If your deployment uses BOSH DNS, which is the default, you cannot use this field to override the DNS servers used in containers.

36. For **DNS Search Domains**, enter DNS search domains for your containers as a comma-separated list. DNS on your containers appends these names to its host names, to resolve them into full domain names.

DNS Search Domains

example.com, myapps.com

DNS search domains to be used in containers. A comma-separated list can be specified.

37. For **Database Connection Timeout**, set the connection timeout for clients of the policy server and silk databases. The default value is `120`. You may need to increase this value if your deployment experiences timeout issues related to Container-to-Container Networking.

38. (Optional) TCP Routing is disabled by default. You should enable this feature if your DNS sends TCP traffic through a load balancer rather than directly to a TCP router. To enable TCP routing:

- a. Select **Enable TCP Routing**.
- b. For **TCP Routing Ports**, enter a single port or a range of ports for the load balancer to forward to. These are the same ports that you configured in the [Pre-Deployment Steps](#) of the *Enabling TCP Routing* topic.
 - To support multiple TCP routes, Pivotal recommends allocating multiple ports.
 - To allocate a list of ports rather than a range:
 1. Enter a single port in the **TCP Routing Ports** field.
 2. After deploying PAS, follow the directions in [Configuring a List of TCP Routing Ports](#) to add TCP routing ports using the cf CLI.

Enable TCP requests to your apps via specific ports on the TCP router. You will want to configure a load balancer to forward these TCP requests to the TCP routers. If you do not have a load balancer, then you can also send traffic directly to the TCP router.*

☐ Select this option if you prefer to enable TCP Routing at a later time

☒ Enable TCP Routing

TCP Routing Ports (one-time configuration, if you want to update this value you can via the CF CLI) *

1024-1123

- c. Return to the top of the **Networking** screen. In **TCP Router IPs** field, make sure you have entered IP addresses within your subnet CIDR block. These will be the same IP addresses you configured your load balancer with in [Pre-Deployment Steps](#), unless you configured DNS to resolve the TCP domain name directly to an IP you've chosen for the TCP router.
- d. (Optional) To disable TCP routing, click **Select this option if you prefer to enable TCP Routing at a later time** For more information, see the [Configuring TCP Routing in PAS](#) [topic](#).

39. Click **Save**.

Step 5: Configure Application Containers

1. Select **Application Containers**.

Enable microservice frameworks, private Docker registries, and other services that support your applications at a container level.

- ☒ Enable Custom Buildpacks
- ☒ Allow SSH access to app containers
- ☒ Enable SSH when an app is created
- ☒ Enable the GrootFS container image plugin for Garden RunC

☐ Router uses TLS to verify application identity

Private Docker Insecure Registry Whitelist

10.10.10.10:8888,example.com:8888

Docker Images Disk-Cleanup Scheduling on Cell VMs*

- ☐ Never clean up Cell disk-space
- ☐ Routinely clean up Cell disk-space
- ☒ Clean up disk-space once threshold is reached

Threshold of Disk-Used (MB) (min: 1) *

10240

- The **Enable Custom Buildpacks** checkbox governs the ability to pass a custom buildpack URL to the `-b` option of the `cf push` command. By default, this ability is enabled, letting developers use custom buildpacks when deploying apps. Disable this option by disabling the checkbox. For more information about custom buildpacks, refer to the [buildpacks](#) section of the PCF documentation.
- The **Allow SSH access to app containers** checkbox controls SSH access to application instances. Enable the checkbox to permit SSH access across your deployment, and disable it to prevent all SSH access. See the [Application SSH Overview](#) topic for information about SSH access permissions at the space and app scope.
- If you want to enable SSH access for new apps by default in spaces that allow SSH, select **Enable SSH when an app is created**. If you deselect the checkbox, developers can still enable SSH after pushing their apps by running `cf enable-ssh APP-NAME`.
- If you want to disable the Garden Root filesystem (GrootFS), deselect the **Enable the GrootFS container image plugin for Garden RunC** checkbox. Pivotal recommends using this plugin, so it is enabled by default. However, some external components are sensitive to dependencies with filesystems such as GrootFS. If you experience issues, such as antivirus or firewall compatibility problems, deselect the checkbox to roll back to the plugin that is built into Garden RunC. For more information about GrootFS, see [Component: Garden](#) and [Container Mechanics](#).

 **Note:** If you modify this setting, Pivotal recommends recreating all VMs in the BOSH Director config. You can do this by selecting the **Recreate all VMs** checkbox in the **Director Config** pane of the BOSH Director tile before you redeploy.

- To enable Gorouter to verify app identity using TLS, select the **Router uses TLS to verify application identity** checkbox.

Verifying app identity using TLS enables encryption between router and app containers and guards against misrouting during control plane failures. For more information about Gorouter route consistency modes, see [Preventing Misrouting](#) in *HTTP Routing*.

 **warning:** TLS routing requires an additional 32 MB of RAM capacity on Diego cells per app instance. It also requires additional CPU capacity on Diego cells. If the total amount of Diego cell memory available is less than 32 MB times the number of running app instances, scale your Diego cells before configuring the Gorouter with TLS.

 **Warning:** You may see an increase of memory and CPU usage for your Gorouters after enabling TLS routing. If the total amount of memory and CPU usage of the Gorouters in your environment are close to the size limit, scale your Gorouters before enabling TLS routing.

- You can configure Pivotal Application Service (PAS) to run app instances in Docker containers by supplying their IP address ranges in the **Private Docker Insecure Registry Whitelist** textbox. See the [Using Docker Registries](#) topic for more information.
- Select your preference for **Docker Images Disk-Cleanup Scheduling on Cell VMs**. If you choose **Clean up disk-space once threshold is reached**, enter a **Threshold of Disk-Used** in megabytes. For more information about the configuration options and how to configure a threshold, see [Configuring Docker Images Disk-Cleanup Scheduling](#).
- Enter a number in the **Max Inflight Container Starts** textbox. This number configures the maximum number of started instances across the Diego cells in your deployment. For more information about this feature, see [Setting a Maximum Number of Started Containers](#).
- Under **Enabling NFSv3 volume services**, select **Enable** or **Disable**. NFS volume services allow application developers to bind existing NFS volumes to their applications for shared file access. For more information, see the [Enabling NFS Volume Services](#) topic.

 **Note:** In a clean install, NFSv3 volume services is enabled by default. In an upgrade, NFSv3 volume services is set to the same setting as it was in the previous deployment.

- (Optional) To configure LDAP for NFSv3 volume services, do the following:

Enabling NFSv3 volume services will allow application developers to bind existing NFS volumes to their applications for shared file access. *

☒ Enable

LDAP Service Account User

LDAP Service Account Password

LDAP Server Host

LDAP Server Port

LDAP User Fully-Qualified Domain Name

☐ Disable

Format of timestamps in Diego logs*

☒ RFC3339 timestamps (e.g. 2018-02-09T00:54:13.479724884Z)

☐ Seconds since the Unix epoch (e.g. 1518137653.479724884)

Save

- For **LDAP Service Account User**, enter the username of the service account in LDAP that will manage volume services.
- For **LDAP Service Account Password**, enter the password for the service account.
- For **LDAP Server Host**, enter the hostname or IP address of the LDAP server.
- For **LDAP Server Port**, enter the LDAP server port number. If you do not specify a port number, Ops Manager uses 389.
- For **LDAP User Fully-Qualified Domain Name**, enter the fully qualified path to the LDAP service account. For example, if you have a service account named `volume-services` that belongs to organizational units (OU) named `service-accounts` and `my-company`, and your domain is named `domain`, the fully qualified path looks like the following:

```
CN=volume-services,OU=service-accounts,OU=my-company,DC=domain,DC=com
```

- By default, PAS manages container images using the [GrootFS](#) plugin for Garden-runC. If you experience issues with GrootFS, you can disable the plugin and use the image plugin built into Garden-runC.

13. Select the **Format of timestamps in Diego logs**, either **RFC3339 timestamps** or **Seconds since the Unix epoch**. Fresh PAS v2.2 installations default to **RFC3339 timestamps**, while upgrades to PAS v2.2 from previous versions default to **Seconds since the Unix epoch**.
14. You can optionally modify the **Default health check timeout**. The value configured for this field is the amount of time allowed to elapse between starting up an app and the first healthy response from the app. If the health check does not receive a healthy response within the configured timeout, then the app is declared unhealthy. The default timeout is seconds and the maximum configurable timeout is seconds.
15. Click **Save**.

Step 6: Configure Application Developer Controls

1. Select **Application Developer Controls**.

Configure restrictions and default settings for applications pushed to Application Service.

Maximum File Upload Size (MB) (min: 1024, max: 2048) *

Default App Memory (MB) (min: 64, max: 2048) *

Default App Memory Quota per Org (MB) (min: 10240, max: 102400) *

Maximum Disk Quota per App (MB) (min: 512, max: 20480) *

Default Disk Quota per App (MB) (min: 512, max: 20480) *

Default Service Instances Quota per Org (min: 0, max: 1000) *

Staging Timeout (Seconds) *

☐ Allow Space Developers to manage network policies

☒ Enable Service Discovery for Apps

Save

2. Enter the **Maximum File Upload Size (MB)**. This is the maximum size of an application upload.
3. Enter the **Default App Memory (MB)**. This is the amount of RAM allocated by default to a newly pushed application if no value is specified with the cf CLI.
4. Enter the **Default App Memory Quota per Org**. This is the default memory limit for all applications in an org. The specified limit only applies to the first installation of PAS. After the initial installation, operators can use the cf CLI to change the default value.

5. Enter the **Maximum Disk Quota per App (MB)**. This is the maximum amount of disk allowed per application.

 **Note:** If you allow developers to push large applications, PAS may have trouble placing them on Cells. Additionally, in the event of a system upgrade or an outage that causes a rolling deploy, larger applications may not successfully re-deploy if there is insufficient disk capacity. Monitor your deployment to ensure your Cells have sufficient disk to run your applications.

6. Enter the **Default Disk Quota per App (MB)**. This is the amount of disk allocated by default to a newly pushed application if no value is specified with the cf CLI.
7. Enter the **Default Service Instances Quota per Org**. The specified limit only applies to the first installation of PAS. After the initial installation, operators can use the cf CLI to change the default value .
8. Enter the **Staging Timeout (Seconds)**. When you stage an application droplet with the Cloud Controller, the server times out after the number of seconds you specify in this field.
9. Select the **Allow Space Developers to manage network policies** checkbox to permit developers to manage their own network policies for their applications.
10. The **Enable Service Discovery for Apps** checkbox, which enables service discovery between applications, is enabled by default. To disable this feature, clear this checkbox. For more information about application service discovery, see the [App Service Discovery](#) section of the *Understanding Container-to-Container Networking* topic.
11. Click **Save**.

Step 7: Review Application Security Group

Setting appropriate [Application Security Groups](#) is critical for a secure deployment. Type ☐ in the box to acknowledge that once the Pivotal Application Service (PAS) deployment completes, you will review and set the appropriate application security groups. See [Restricting App Access to Internal PCF Components](#) for instructions.

Setting appropriate Application Security Groups that control application network policy is the responsibility of the Elastic Runtime administration team. Please refer to the Application Security Groups topic in the Pivotal Cloud Foundry documentation for more detail on completing this activity after the Elastic Runtime deployment completes.

Type X to acknowledge that you understand this message *

Save

Step 8: Configure Authentication and Enterprise SSO

1. Select **Authentication and Enterprise SSO**.

Configure your user store access, which can be an internal user store (managed by Cloud Foundry's UAA) or an external user store (LDAP or SAML). You can also adjust the lifetimes of authentication tokens.

Configure your UAA user account store with either internal or external authentication mechanisms *

☒ Internal UAA (provided by Elastic Runtime; configure your password policy below)

Minimum Password Length *

Minimum Uppercase Characters Required for Password *

Minimum Lowercase Characters Required for Password *

Minimum Numerical Digits Required for Password *

Minimum Special Characters Required for Password *

Maximum Password Entry Attempts Allowed *

2. To authenticate user sign-ons, your deployment can use one of three types of user database: the UAA server's internal user store, an external SAML identity provider, or an external LDAP server.

- To use the internal UAA, select the **Internal** option and follow the instructions in the [Configuring UAA Password Policy](#) topic to configure your password policy.
- To connect to an external identity provider through SAML, scroll down to select the **SAML Identity Provider** option and follow the instructions in the [Configuring PCF for SAML](#) section of the *Configuring Authentication and Enterprise SSO for Pivotal Application Service (PAS)* topic.
- To connect to an external LDAP server, scroll down to select the **LDAP Server** option and follow the instructions in the [Configuring LDAP](#) section of the *Configuring Authentication and Enterprise SSO for PAS* topic.

3. Click **Save**.

Step 9: Configure UAA

1. Select **UAA**.

2. (Optional) Under **JWT Issuer URI**, enter the URI that UAA uses as the issuer when generating tokens.

JWT Issuer URI

3. Under **SAML Service Provider Credentials**, enter a certificate and private key to be used by UAA as a SAML Service Provider for signing outgoing SAML authentication requests. You can provide an existing certificate and private key from your trusted Certificate Authority or generate a self-signed certificate. The following domain must be associated with the certificate: `*.login.YOUR-SYSTEM-DOMAIN`.

Note: The Pivotal Single Sign-On Service and Pivotal Spring Cloud Services tiles require the `*.login.YOUR-SYSTEM-DOMAIN`.

- If the private key specified under **Service Provider Credentials** is password-protected, enter the password under **SAML Service Provider Key**

SAML Service Provider Credentials *

-----BEGIN CERTIFICATE-----

 U
 H
 M
 -----END CERTIFICATE-----

[Change](#)

SAML Service Provider Key Password

Secret

Password.

- (Optional) To override the default value, enter a custom SAML Entity ID in the **SAML Entity ID Override** field. By default, the SAML Entity ID is `http://login.YOUR-SYSTEM-DOMAIN` where `YOUR-SYSTEM-DOMAIN` is set in the **Domains > System Domain** field.
- For **Signature Algorithm**, choose an algorithm from the dropdown menu to use for signed requests and assertions. The default value is `SHA256`.
- (Optional) In the **Apps Manager Access Token Lifetime**, **Apps Manager Refresh Token Lifetime**, **Cloud Foundry CLI Access Token Lifetime**, and **Cloud Foundry CLI Refresh Token Lifetime** fields, change the lifetimes of tokens granted for Apps Manager and Cloud Foundry Command Line Interface (cf CLI) login access and refresh. Most deployments use the defaults.

Apps Manager Access Token Lifetime (in seconds) *

1209600

Customize Password Label (on login page) *

Password

Proxy IPs Regular Expression *

10\.\d{1,3}\.\d{1,3}\.\d{1,3}|192\.168\.\d{1,3}

[Save](#)

8. (Optional) In the **Global Login Session Max Timeout** and **Global Login Session Idle Timeout** fields, change the maximum number of seconds before a global login times out. These fields apply to the following:
 - **Default zone sessions:** Sessions in Apps Manager, PCF Metrics, and other web UIs that use the UAA default zones
 - **Identity zone sessions:** Sessions in apps that use a UAA identity zone, such as a Single Sign-On service plan
9. (Optional) Customize the text prompts used for username and password from the cf CLI and Apps Manager login popup by entering values for **Customize Username Label (on login page)** and **Customize Password Label (on login page)**.
10. (Optional) The **Proxy IPs Regular Expression** field contains a pipe-delimited set of regular expressions that UAA considers to be reverse proxy IP addresses. UAA respects the `x-forwarded-for` and `x-forwarded-proto` headers coming from IP addresses that match these regular expressions. To configure UAA to respond properly to Gorouter or HAProxy requests coming from a public IP address, append a regular expression or regular expressions to match the public IP address.
11. You can configure UAA to use an internal MySQL database provided with PCF, or you can configure an external database provider. Follow the procedures in either the [Internal Database Configuration](#) or the [External Database Configuration](#) section below.

 **Note:** If you are performing an upgrade, do not modify your existing internal database configuration or you may lose data. You must migrate your existing data before changing the configuration. See [Upgrading Pivotal Cloud Foundry](#) for additional upgrade information, and contact [Pivotal Support](#) for help.

Internal Database Configuration

When you configure the UAA to use an internal MySQL database, it uses the type of database selected in the **Databases** pane. See the [Configure Internal Databases](#) section for details.

1. Select **Internal MySQL**.

Choose the location of your UAA database *

☒ Internal MySQL (preferred for complete high-availability)

☐ External (preferred if, for example, you use AWS RDS)

 **Note:** If you configure your system databases as external in the **Databases** pane, selecting Internal MySQL in the **UAA** pane has no effect.

2. Click **Save**.
3. Ensure that you complete the [Configure Internal MySQL](#) step later in this topic to configure high availability for your internal MySQL databases.

External Database Configuration

1. From the **UAA** section in Pivotal Application Service (PAS), select **External**.

Choose the location of your UAA database *

☐ Internal MySQL (preferred for complete high-availability)

☒ External (preferred if, for example, you use AWS RDS)

Hostname *

TCP Port *

Username *

Password *

2. For **Hostname**, enter the hostname of the database server.
3. For **TCP Port**, enter the port of the database server.
4. For **User Account and Authentication database username**, specify a unique username that can access this specific database on the database server.
5. For **User Account and Authentication database password**, specify a password for the provided username.
6. Click **Save**.

Step 10: Configure CredHub

 **Note:** Enabling CredHub is not required. However, you cannot leave the fields under **Encryption Keys** blank. If you do not intend to use CredHub, enter any text in the **Name** and **Key** fields as placeholder values.

1. Select **CredHub**.
2. Choose the location of your CredHub database. PAS includes this CredHub database for services to store their service instance credentials.

 **Note:** You cannot choose **Internal** for the CredHub database if you choose **External** for your System Databases. See [Configure System Databases](#) below.

Configure the CredHub Server

Choose the location of your CredHub database *

☒ Internal MySQL (preferred for complete high-availability)

☐ External (preferred if, for example, you use Google Cloud SQL)

If you chose **External**, enter the following:

- **Hostname.** This is the IP address of your database server.
- **TCP Port.** This is the port of your database server, such as `3306`.
- **Username.** This is a unique username that can access your CredHub database on the database server.
- **Password.** This is the password for the provided username.
- **Database CA Certificate.** This certificate is used when encrypting traffic to and from the database.

3. Under **Encryption Keys**, specify one or more keys to use for encrypting and decrypting the values stored in the CredHub database.

Encryption Keys

Name *

Name of the encryption key.

Provider*

Internal

Key *

Secret

☐ Primary

- **Name.** This is the name of the encryption key.
 - If you plan to use internal encryption, enter any key name.
 - If you plan to use an HSM as your encryption provider, enter a key name that already exists on your HSM or a new key name. For each new key name, CredHub generates a key in **HSM Provider Partition** that you configure below.
- **Provider.** This is the provider of the encryption key. If you plan to configure an HSM provider and HSM servers below, select **HSM**. Otherwise, select **Internal**.
- **Key.** If you select internal encryption, this key is used for encrypting all data. The key must be at least 20 characters long.
 - If you selected **Internal** above, enter a randomly generated value under **Key**.
 - If you selected **HSM** above, enter a placeholder value under **Key**. CredHub does not use this key for encryption. However, you cannot leave the **Key** field blank.
- **Primary.** This checkbox is used for marking the key you specified above as the primary encryption key. You must mark one key as **Primary**. Do not mark more than one key as **Primary**.

 **Note:** For information about using additional keys for key rotation, see the [Rotating Runtime CredHub Encryption Keys](#) topic.

4. (Optional) To configure CredHub to use an HSM, complete the following fields:

- **HSM Provider Partition.** This is the name of the HSM provider partition.
- **HSM Provider Partition Password.** This password is used to access the HSM provider partition.
- **HSM Provider Client Certificate.** This is the client certificate for the HSM. For more information, see [Create and Register HSM Clients](#) in the

Preparing CredHub HSMs for Configuration topic.

- In the **HSM Provider Servers** section, click **Add** to add an HSM server. You can add multiple HSM servers. For each HSM server, complete the following fields:
 - **Host Address.** This is the host name or IP address of the HSM server.
 - **Port.** This is the port of the HSM server. If you do not know your port address, enter `1792`.
 - **Partition Serial Number.** This is the serial number of the HSM partition.
 - **HSM Certificate.** This is the certificate for the HSM server. The HSM presents this certificate to CredHub to establish a two-way TLS connection.

5. If your deployment uses any PCF services that support storing service instance credentials in CredHub and you want to enable this feature, select the **Secure Service Instance Credentials** checkbox.
6. Click **Save**.
7. Select the **Resource Config** pane.
8. Under the **Job** column of the **CredHub** row, set the number of instances to `2`. This is the minimum instance count required for high availability.
9. Click **Save**.

For more information about using CredHub for securing service instance credentials, see [Securing Service Instance Credentials with Runtime CredHub](#).

Step 11: Configure System Databases

You can configure PAS to use an internal MySQL database provided with PCF, or you can configure an external database provider for the databases required by PAS.

Note: If you are performing an upgrade, do not modify your existing internal database configuration or you may lose data. You must migrate your existing data first before changing the configuration. Contact Pivotal Support for help. See [Upgrading Pivotal Cloud Foundry](#) for additional upgrade information.

Internal Database Configuration

If you want to use internal databases for your deployment, perform the following steps:

1. Select **Databases**.
2. Select one of the **Internal Databases** options:
 - **Internal Databases - MySQL - Percona XtraDB Cluster** uses [Percona Server](#) with TLS encryption between server cluster nodes.
 - **Internal Databases - MySQL - MariaDB Galera Cluster** uses [MariaDB](#) with cluster nodes communicating over plaintext.

⚠ warning: Changing existing internal databases from **MySQL - MariaDB Galera Cluster** to **MySQL - Percona XtraDB Cluster** migrates the databases after you click **Apply Changes**, causing temporary system downtime. See [Migrate to Internal Percona MySQL](#) for details.

Choose the location of your system databases. Please consult the documentation for migrating existing installations from MariaDB to Percona. *

- ☒ Internal Databases - MySQL - Percona XtraDB Cluster
- ☐ Internal Databases - MySQL - MariaDB Galera Cluster (deprecated - planned to be removed in PAS 2.4)
- ☐ External Databases - (e.g. AWS RDS)

Save

3. Click **Save**.

Then proceed to [Step 12: \(Optional\) Configure Internal MySQL](#) to configure high availability for your internal MySQL databases.

External Database Configuration

⚠ warning: Protect whichever database you use in your deployment with a password.

To create your Pivotal Application Service (PAS) databases, follow the procedure below.

💡 Note: Exact configurations depend on your database provider. The following procedure uses AWS RDS as an example.

1. Add the `ubuntu` account key pair from your IaaS deployment to your local SSH profile so you can access the Ops Manager VM. For example, in AWS, you add a key pair created in AWS:

```
$ ssh-add aws-keypair.pem
```

2. SSH in to your Ops Manager using the Ops Manager FQDN and the username `ubuntu`:

```
$ ssh ubuntu@OPS-MANAGER-FQDN
```

3. Log in to your MySQL database instance using the appropriate hostname and user login values configured in your IaaS account. For example, to log in to your AWS RDS instance, run the following MySQL command:

```
$ mysql --host=RDSHOSTNAME --user=RDSUSERNAME --password=RDSPASSWORD
```

4. Run the following MySQL commands to create databases for the PAS components that require a relational database:

```
CREATE database ccdb;
CREATE database notifications;
CREATE database autoscale;
CREATE database app_usage_service;
CREATE database routing;
CREATE database diego;
CREATE database account;
CREATE database nfsvolume;
CREATE database networkpolicyserver;
CREATE database silk;
CREATE database locket;
CREATE database uaa;
CREATE database credhub;
```

💡 Note: The command `CREATE database credhub;` is optional if you have no CredHub instances. By default, CredHub has `0` instances.

5. Type `exit` to quit the MySQL client, and `exit` again to close your connection to the Ops Manager VM.

6. In PAS, select **Databases**.

7. Select the **External Databases** option.

 **Note:** If you configure databases as external, you cannot configure an internal database in the **UAA** pane.

8. For **Hostname**, enter the hostname of the database server.
9. For **TCP Port**, enter the port of the database server.
10. Each component that requires a relational database has two corresponding fields: one for the database username and one for the database password. For each set of fields, specify a unique username that can access this specific database on the database server and a password for the provided username.

 **Note:** Ensure that the networkpolicyserver database user has the `ALL PRIVILEGES` permission.

11. Click **Save**.

Step 12: (Optional) Configure Internal MySQL

 **Note:** You only need to configure this section if you have selected one of the **Internal Databases - MySQL** options in the **Databases** section.

To use internal MySQL in High Availability configuration, you define a load balancer rule that lets PAS components send queries a single hostname backed by two redundant proxies. Each proxy then directs query traffic to three MySQL server nodes.

1. Allocate an internal load balancer rule to balance traffic between two static IP addresses. The static IP addresses cannot be within the range that that you have reserved for PAS.

The load balancer rule is separate from the software provided by Pivotal, and you need to define it within your infrastructure.

- **Make your idle time out long enough to not interrupt long-running queries.** When queries take a long time, the load balancer can time out and interrupt the query.
For example, [AWS's Elastic Load Balancer](#) has a default idle timeout of 60 seconds, so queries that take longer than this duration sever the MySQL connection and return an error.
- **Configure a healthcheck or monitor, using TCP against port 1936.** This defaults to TCP port `1936`, to maintain backwards compatibility with previous releases. This port is not configurable. Unauthenticated healthchecks against port 3306 may cause the service to become unavailable and require manual intervention to fix.
- **Configure the load balancer to route traffic for TCP port 3306 to the IPs of all proxy instances on TCP port 3306.**
- Record the hostname of the load balancer rule and the two static IP addresses.

 **warning:** You must configure a load balancer to achieve complete high availability.

2. From the PAS tile in Ops Manager, Select **Internal MySQL**.
3. In the **MySQL Proxy IPs** field, enter the static IP addresses used by the internal MySQL load balancer rule.

Only configure this section if you selected Internal Databases - MySQL in the previous Databases section.

A proxy tier routes MySQL connections from internal components to healthy cluster nodes. Configure DNS and/or your own load balancer to point to multiple proxy instances for increased availability. TCP healthchecks can be configured against port 1936.

The automated backups functionality works with any S3-compatible file store that can receive your backup files.

MySQL Proxy IPs

MySQL Service Hostname

4. For **MySQL Service Hostname**, enter the IP address or hostname for your load balancer. If you leave this field blank, components are configured with the IP address of the first proxy instance entered above.

5. In the **Replication canary time period** field, leave the default of 30 seconds or modify the value based on the needs of your deployment. Lower numbers cause the canary to run more frequently, which means that the canary reacts more quickly to replication failure but adds load to the database.
6. In the **Replication canary read delay** field, leave the default of 20 seconds or modify the value based on the needs of your deployment. This field configures how long the canary waits, in seconds, before verifying that data is replicating across each MySQL node. Clusters under heavy load can experience a small replication lag as write-sets are committed across the nodes.
7. (**Required**): In the **E-mail address** field, enter the email address where the MySQL service sends alerts when the cluster experiences a replication issue or when a node is not allowed to auto-rejoin the cluster.
8. To prohibit the creation of command line history files on the MySQL nodes, disable the **Allow Command History** checkbox.
9. To allow the admin and roadmin to connect from any remote host, enable the **Allow Remote Admin Access** checkbox. When the checkbox is disabled, admins must `bosh ssh` into each MySQL VM to connect as the MySQL super user.

 **Note:** Network configuration and Application Security Groups restrictions may still limit a client's ability to establish a connection with the databases.

10. For **Cluster Probe Timeout**, enter the maximum amount of time, in seconds, that a new node will search for existing cluster nodes. If left blank, the default value is 10 seconds.

Replication canary time period *

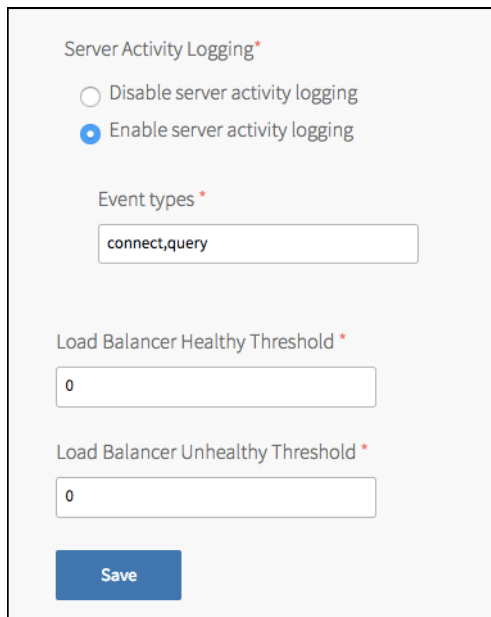

Replication canary read delay *

E-mail address (required) *

☒ Allow Command History

Cluster Probe Timeout

11. For **Max Connections**, enter the maximum number of connections allowed to the database. If left blank, the default value is 1500.
12. If you want to log audit events for internal MySQL, select **Enable server activity logging** under **Server Activity Logging**.
 - a. For the **Event types** field, you can enter the events you want the MySQL service to log. By default, this field includes `connect` and `query`, which tracks who connects to the system and what queries are processed.

The screenshot shows a configuration panel for a MySQL Proxy instance. It includes the following fields and controls:

- Server Activity Logging***: Two radio buttons. The first is "Disable server activity logging" (unselected). The second is "Enable server activity logging" (selected).
- Event types ***: A text input field containing the value "connect,query".
- Load Balancer Healthy Threshold ***: A text input field containing the value "0".
- Load Balancer Unhealthy Threshold ***: A text input field containing the value "0".
- Save**: A blue button at the bottom of the panel.

13. Enter values for the following fields:

- **Load Balancer Healthy Threshold**: Specifies the amount of time, in seconds, to wait until declaring the MySQL Proxy instance started. This allows an external load balancer time to register the instance as healthy.
- **Load Balancer Unhealthy Threshold**: Specifies the amount of time, in seconds, that the MySQL Proxy continues to accept connections before shutting down. During this period, the Healthcheck reports as unhealthy to cause load balancers to fail over to other proxies. You must enter a value greater than or equal to the maximum time it takes your load balancer to consider a proxy instance unhealthy, given repeated failed healthchecks.

14. If you want to enable the MySQL interruptor feature, select the checkbox to **Prevent node auto re-join**. This feature stops all writes to the MySQL database if it notices an inconsistency in the dataset between the nodes. For more information, see the [Interruptor](#) section in the MySQL for PCF documentation.

15. Click **Save**.

For more information on how to monitor the node health of your MySQL Proxy instances, see [Using the MySQL Proxy](#).

Step 13: Configure File Storage

For production-level PCF deployments on vSphere, the recommended selection is **External S3-Compatible** and the use of an external filestore. For more information about production-level PCF deployments on vSphere, see the [Reference Architecture for Pivotal Cloud Foundry on vSphere](#).

For more factors to consider when selecting file storage, see [Considerations for Selecting File Storage in Pivotal Cloud Foundry](#).

Internal Filestore

Internal file storage is only appropriate for small, non-production deployments.

To use the PCF internal filestore, perform the following steps:

1. In the Pivotal Application Service (PAS) tile, select **File Storage**.
2. Select **Internal WebDAV**, and click **Save**.

External S3 or Ceph Filestore

To use an external S3-compatible filestore for PAS file storage, perform the following steps:

1. In the PAS tile, select **File Storage**.

2. Select the **External S3-Compatible Filestore** option and complete the following fields:

- Enter the `https://` **URL Endpoint** for your region.
For example, in the **us-west-2** region, enter `https://s3-us-west-2.amazonaws.com/`.
- If you use an AWS instance profile to manage role information for your filestore, select the **S3 AWS with Instance Profile** checkbox. For more information, see [AWS Identity and Access Management](#) in the AWS documentation.

☒ S3 AWS with Instance Profile

Access Key (required if not using S3 AWS with Instance Profile)

Secret Key (required if not using S3 AWS with Instance Profile)

Secret

[Cancel](#)

- Alternatively, enter the **Access Key** and **Secret Key** of the `pcf-user` you created when configuring AWS for PCF. If you select the **S3 AWS with Instance Profile** checkbox and also enter an **Access Key** and **Secret Key**, the instance profile will overrule the Access Key and Secret Key.
- From the **S3 Signature Version** dropdown, select **V4 Signature**. For more information about S4 signatures, see [Signing AWS API Requests](#) in the AWS documentation.
- For **Region**, enter the region in which your S3 buckets are located. `us-west-2` is an example of an acceptable value for this field.
- Select **Server-side Encryption** to encrypt the contents of your S3 filestore. This option is only available for AWS S3.
- (Optional) If you selected **Server-side Encryption**, you can also specify a **KMS Key ID**. PAS uses the KMS key to encrypt files uploaded to the blobstore. If you do not provide a KMS Key ID, PAS uses the default AWS key. For more information, see [Protecting Data Using Server-Side Encryption with AWS KMS-Managed Keys \(SSE-KMS\)](#).
- Enter names for your S3 buckets:

| Ops Manager Field | Value | Description |
|------------------------|-----------------------|---|
| Buildpacks Bucket Name | pcf-buildpacks-bucket | This S3 bucket stores app buildpacks. |
| Droplets Bucket Name | pcf-droplets-bucket | This S3 bucket stores app droplets. Pivotal recommends that you use a unique bucket name for droplets, but you can also use the same name as above. |
| Packages Bucket Name | pcf-packages-bucket | This S3 bucket stores app packages. Pivotal recommends that you use a unique bucket name for packages, but you can also use the same name as above. |
| Resources Bucket Name | pcf-resources-bucket | This S3 bucket stores app resources. Pivotal recommends that you use a unique bucket name for app resources, but you can also use the same name as above. |

- Configure the following depending on whether your S3 buckets have versioning enabled:
 - Versioned S3 buckets:** Enable the **Use versioning for backup and restore** checkbox to archive each bucket to a version.
 - Unversioned S3 buckets:** Disable the **Use versioning for backup and restore** checkbox, and enter a backup bucket name for each active bucket. The backup bucket name must be different from the name of the active bucket it backs up.

☐ Use versioning for backup and restore.
 (All of the above buckets must have versioning enabled and use the V4 S3 Signature Version).

If versioning is not enabled or supported, you can configure separate buckets below for backups. More information at <https://docs.pivotal.io/pivotalcf/2-1/customizing/backup-restore/backup-pcf-bbr.html>.

Backup Region

Backup Buildpacks Bucket Name

Backup Droplets Bucket Name

Backup Packages Bucket Name

For more information

about setting up external S3 blobstores, see the [Backup and Restore with External Blobstores](#) topic in the Cloud Foundry documentation.

3. Click **Save**.

 **Note:** For more information regarding AWS S3 Signatures, see the [Authenticating Requests](#) topic in the AWS documentation.

Step 14: (Optional) Configure System Logging

You can configure system logging in PAS to forward log messages from PAS component VMs to an external service. Pivotal recommends forwarding logs to an external service for use in troubleshooting.

 **Note:** The following instructions explain how to configure system logging for PAS component VMs. To forward logs from PCF tiles to an external service, you must also configure system logging in each tile. See the documentation for the given tiles for information about configuring system logging.

To configure system logging in PAS, do the following:

1. In the PAS **Settings** tab, select the **System Logging** pane. The following image shows the **System Logging** pane.

Optionally configure rsyslog to forward platform component logs to an external service. If you do not fill these fields, platform logs will not be forwarded but will remain available on the component VMs and for download via Ops Manager.

Address

Port

Transport Protocol

Encrypt syslog using TLS?*

- ☒ No
☐ Yes

Syslog Drain Buffer Size (# of messages) *

☒ Include container metrics in SysLog Drains

☒ Enable Cloud Controller security event logging

☐ Use TCP for file forwarding local transport

☒ Don't Forward Debug Logs

Custom rsyslog Configuration

Save

2. For **Address**, enter the IP address of the syslog server.
3. For **Port**, enter the port of the syslog server. The default port for a syslog server is `514`.

Note: The host must be reachable from the PAS network and accept UDP or TCP connections. Ensure the syslog server listens on external interfaces.

4. For **Transport Protocol**, select a transport protocol for log forwarding.
5. For **Encrypt syslog using TLS?**, select **Yes** to use TLS encryption when forwarding logs to a remote server.
 - a. For **Permitted Peer**, enter either the name or SHA1 fingerprint of the remote peer.
 - b. For **TLS CA Certificate**, enter the TLS CA certificate for the remote server.
6. For **Syslog Drain Buffer Size**, enter the number of messages from the Loggregator Agent that the Doppler server can store before it begins to drop messages. See the [Loggregator Guide for Cloud Foundry Operators](#) topic for more details.
7. Disable the **Include container metrics in Syslog Drains** checkbox to prevent the [CF Drain CLI plugin](#) from including app container metrics in syslog drains. This feature is enabled by default.

8. Enable the **Enable Cloud Controller security event logging** checkbox to include security events in the log stream. This feature logs all API requests, including the endpoint, user, source IP address, and request result, in the Common Event Format (CEF).
9. Enable the **Use TCP for file forwarding local transport** checkbox to transmit logs over TCP. This prevents log truncation, but may cause performance issues.
10. Disable the **Don't Forward Debug Logs** checkbox to forward DEBUG syslog messages to an external service. This checkbox is enabled by default.

Note: Some PAS components generate a high volume of DEBUG syslog messages. Enabling the **Don't Forward Debug Logs** checkbox prevents PAS components from forwarding the DEBUG syslog messages to external services. However, PAS still writes the messages to the local disk.

11. For **Custom rsyslog Configuration**, enter a custom syslog rule. For more information about adding custom syslog rules, see [Customizing Syslog Rules](#).
12. Click **Save**.

To configure Ops Manager for system logging, see the [Settings](#) section in the *Using the Ops Manager Interface* topic.

Step 15: (Optional) Customize Apps Manager

This section describes how to configure **Custom Branding** and **Apps Manager** to customize the appearance and functionality of Apps Manager. For more information about the **Custom Branding** configuration settings, see [Custom Branding Apps Manager](#).

1. Select **Custom Branding**. Use this section to configure the text, colors, and images of the interface that developers see when they log in, create an account, reset their password, or use Apps Manager.

Customize colors, images, and text for Apps Manager and the Cloud Foundry login portal.

Company Name

Accent Color

2. Click **Save** to save your settings in this section.
3. Select **Apps Manager**.

Configure Apps Manager

☒ Enable Invitations

☐ Display Marketplace Service Plan Prices

Supported currencies as JSON *

```
{ "usd": "$", "eur": "€" }
```

Product Name

Marketplace Name

Customize Sidebar Links Add

You may configure up to 10 links in the Apps Manager sidebar.

- ▶ Marketplace 🗑️
- ▶ Docs 🗑️
- ▶ Tools 🗑️

Apps Manager Memory Usage (MB) (min: 128)

Invitations Memory Usage (MB) (min: 256)

Apps Manager Polling Interval *

30

Apps manager polling interval in seconds. As a workaround to reduce load on the Cloud Controller API, increase the polling interval or set to 0 to stop polling. Values between 0 and 30 will default to 30 seconds.

Save

4. Select **Enable Invitations** to enable invitations in Apps Manager. Space Managers can invite new users for a given space, Org Managers can invite new users for a given org, and Admins can invite new users across all orgs and spaces. See the [Inviting New Users](#) section of the *Managing User Roles with Apps Manager* topic for more information.
5. Select **Display Marketplace Service Plan Prices** to display the prices for your services plans in the Marketplace.
6. Enter the **Supported currencies as JSON** to appear in the Marketplace. Use the format `{ "CURRENCY-CODE": "SYMBOL" }`. This defaults to `{ "usd": "$", "eur": "€" }`.
7. Use **Product Name**, **Marketplace Name**, and **Customize Sidebar Links** to configure page names and sidebar links in the **Apps Manager** and **Marketplace** pages.
8. The **Apps Manager Memory Usage (MB)** field sets the memory limit with which to deploy the Apps Manager app. Use this field to increase the memory limit if the app fails to start with an `out of memory` error.
9. The **Invitations Memory Usage (MB)** field sets the memory limit with which to deploy the Invitations app. Use this field to increase the memory limit if the app fails to start with an `out of memory` error.

10. The **Apps Manager Polling Interval** field provides a temporary fix if Apps Manager usage degrades Cloud Controller response times. In this case, you can use this field to reduce the load on the Cloud Controller and ensure Apps Manager remains available while you troubleshoot the Cloud Controller. Pivotal recommends that you do not keep this field modified as a long term fix because it can degrade Apps Manager performance. You can optionally do the following:

- Increase the polling interval above the default of `30` seconds.

 **Note:** If you enter a value between `0` and `30`, the field is automatically set to `30`.

- Disable polling by entering `0`. This stops Apps Manager from refreshing data automatically, but users can update displayed data by reloading Apps Manager manually.

11. Click **Save** to save your settings in this section.

Step 16: (Optional) Configure Email Notifications

PAS uses SMTP to send invitations and confirmations to Apps Manager users. You must complete the **Email Notifications** page if you want to enable end-user self-registration.

1. Select **Email Notifications**.

Configure Simple Mail Transfer Protocol for the Notifications application to send email notifications about your deployment. This application is deployed as an errand in Elastic Runtime. If you do not need this service, leave this section blank and disable the Notifications and Notifications UI errands.

From Email

Address of SMTP Server

Port of SMTP Server

SMTP Server Credentials

[Change](#)

☒ SMTP Enable Automatic STARTTLS

SMTP Authentication Mechanism*

SMTP CRAMMD5 secret

2. Enter your reply-to and SMTP email information.

 **Note:** For GCP, you must use port `2525`. Ports `25` and `587` are not allowed on GCP Compute Engine.

3. Verify your authentication requirements with your email administrator and use the **SMTP Authentication Mechanism** dropdown to select `None`, `Plain`, or `CRAMMD5`. If you have no SMTP authentication requirements, select `None`.

- If you selected `CRAMMD5` as your authentication mechanism, enter a secret in the **SMTP CRAMMD5 secret** field.
- Click **Save**.

Note: If you do not configure the SMTP settings using this form, the administrator must create orgs and users using the cf CLI. See [Creating and Managing Users with the cf CLI](#) for more information.

Step 17: (Optional) Configure App Autoscaler

To use App Autoscaler, you must create an instance of the service and bind it to an app. To create an instance of App Autoscaler and bind it to an app, see [Set Up App Autoscaler](#) in the *Scaling an Application Using App Autoscaler* topic.

- Click **App Autoscaler**.

Configure the App Autoscaler

Autoscaler Instance Count (min: 1) *

Autoscaler API Instance Count (min: 1) *

Metric Collection Interval (min: 60, max: 3600) (min: 60, max: 3600) *

Scaling Interval (min: 15, max: 120) (min: 15, max: 120) *

☐ Verbose Logging

☐ Disable API Connection Pooling

☒ Enable Notifications

Save

- Review the following settings:

- Autoscaler Instance Count:** How many instances of the App Autoscaler service you want to deploy. The default value is `3`. For high availability, set this number to `3` or higher. You should set the instance count to an odd number to avoid split-brain scenarios during leadership elections. Larger environments may require more instances than the default number.
- Autoscaler API Instance Count:** How many instances of the App Autoscaler API you want to deploy. The default value is `1`. Larger environments may require more instances than the default number.
- Metric Collection Interval:** How many seconds of data collection you want App Autoscaler to evaluate when making scaling decisions. The minimum interval is 60 seconds, and the maximum interval is 3600 seconds. The default value is `120`. Increase this number if the metrics you use in your scaling rules are emitted less frequently than the existing Metric Collection Interval.
- Scaling Interval:** How frequently App Autoscaler evaluates an app for scaling. The minimum interval is 15 seconds, and the maximum interval is 120 seconds. The default value is `35`.
- Verbose Logging** (checkbox): Enables verbose logging for App Autoscaler. Verbose logging is disabled by default. Select this checkbox to see more detailed logs. Verbose logs show specific reasons why App Autoscaler scaled the app, including information about minimum and maximum instance limits, App Autoscaler's status. For more information about App Autoscaler logs, see [App Autoscaler Events and Notifications](#).
- Disable API Connection Pooling:** API connection pooling increases performance by reducing the cost associated with establishing new connections. If you do not want to keep connections open for reuse, select this option.

3. Click **Save**.

Step 18: Configure Cloud Controller

1. Click **Cloud Controller**.

Configure the Cloud Controller

Cloud Controller DB Encryption Key

Secret

Enabling CF API Rate Limiting will prevent API consumers from overwhelming the platform API servers. Limits are imposed on a per-user or per-client basis and reset on an hourly interval. *

☐ Enable
 ☒ Disable

Save

2. Enter your **Cloud Controller DB Encryption Key** if all of the following are true:

- You deployed Pivotal Application Service (PAS) previously.
- You then stopped PAS or it crashed.
- You are re-deploying PAS with a backup of your Cloud Controller database.

See [Backing Up Pivotal Cloud Foundry](#) for more information.

3. CF API Rate Limiting prevents API consumers from overwhelming the platform API servers. Limits are imposed on a per-user or per-client basis and reset on an hourly interval.

To disable CF API Rate Limiting, select **Disable** under **Enable CF API Rate Limiting**. To enable CF API Rate Limiting, perform the following steps:

- Under **Enable CF API Rate Limiting**, select **Enable**.
- For **General Limit**, enter the number of requests a user or client is allowed to make over an hour interval for all endpoints that do not have a custom limit. The default value is `2000`.
- For **Unauthenticated Limit**, enter the number of requests an unauthenticated client is allowed to make over an hour interval. The default value is `100`.

4. Click **Save**.

Step 19: Configure Smoke Tests

The Smoke Tests errand runs basic functionality tests against your Pivotal Application Service (PAS) deployment after an installation or update. In this section, choose where to run smoke tests. In the **Errands** section, you can choose whether or not to run the Smoke Tests errand.

1. Select **Smoke Tests**.
2. If you have a shared apps domain, select **Temporary space within the system organization**, which creates a temporary space within the `system` organization for running smoke tests and deletes the space afterwards. Otherwise, select **Specified org and space** and complete the fields to specify where you want to run smoke tests.

Specify a Cloud Foundry organization and space where smoke tests can run if in the future you delete your Elastic Runtime deployment domains.

Choose where to deploy applications when running the smoke tests *

- ☐ Temporary space within the system organization (This is deleted after smoke tests finish.)
- ☒ Specified org and space (The org and space must have a domain available for routing.)

Organization *

Space *

Domain *

Save

3. Click **Save**.

Step 20: (Optional) Enable Advanced Features

The **Advanced Features** section of Pivotal Application Service (PAS) includes new functionality that may have certain constraints. Although these features are fully supported, Pivotal recommends caution when using them in production environments.

Diego Cell Memory and Disk Overcommit

If your apps do not use the full allocation of disk space and memory set in the **Resource Config** tab, you might want use this feature. These fields control the amount to overcommit disk and memory resources to each Diego Cell VM.

For example, you might want to use the overcommit if your apps use a small amount of disk and memory capacity compared to the amounts set in the **Resource Config** settings for **Diego Cell**.

Note: Due to the risk of app failure and the deployment-specific nature of disk and memory use, Pivotal has no recommendation about how much, if any, memory or disk space to overcommit.

To enable overcommit, do the following:

1. Select **Advanced Features**.

Cell Memory Capacity (MB) (min: 1)

Cell Disk Capacity (MB) (min: 1)

2. Enter the total desired amount of Diego cell memory value in the **Cell Memory Capacity (MB)** field. Refer to the **Diego Cell** row in the **Resource Config** tab for the current Cell memory capacity settings that this field overrides.
3. Enter the total desired amount of Diego cell disk capacity value in the **Cell Disk Capacity (MB)** field. Refer to the **Diego Cell** row in the **Resource Config** tab for the current Cell disk capacity settings that this field overrides.
4. Click **Save**.

 **Note:** Entries made to each of these two fields set the total amount of resources allocated, not the overage.

Whitelist for Non-RFC-1918 Private Networks

Some private networks require extra configuration so that internal file storage (WebDAV) can communicate with other PCF processes.

The **Whitelist for non-RFC-1918 Private Networks** field is provided for deployments that use a non-RFC 1918 private network. This is typically a private network other than `10.0.0.0/8`, `172.16.0.0/12`, or `192.168.0.0/16`.

Most PCF deployments do not require any modifications to this field.

To add your private network to the whitelist, do the following:

1. Select **Advanced Features**.
2. Append a new `allow` rule to the existing contents of the **Whitelist for non-RFC-1918 Private Networks** field.

Whitelist for non-RFC-1918 Private Networks *

allow 10.0.0.0/8;;allow 172.16.0.0/12;;allow .

If your Elastic Runtime deployment is using a private network that is not RFC 1918 (10.0.0.0/8, 172.16.0.0/12, 192.168.0.0/16), then you must type in "allow <your-network>;" here. It is important to include the word "allow" and the semi-colon at the end. For example, "allow 172.99.0.0/24;"

Include the word `allow`, the network CIDR range to allow, and a semi-colon (`;`) at the end. For example: `allow 172.99.0.0/24;`

3. Click **Save**.

CF CLI Connection Timeout

The **CF CLI Connection Timeout** field allows you to override the default five second timeout of the Cloud Foundry Command Line Interface (cf CLI) used within your PCF deployment. This timeout affects the cf CLI command used to push PAS errand apps such as Notifications, Autoscaler, and Apps Manager.

Set the value of this field to a higher value, in seconds, if you are experiencing domain name resolution timeouts when pushing errands in PAS.

To modify the value of the **CF CLI Connection Timeout**, perform the following steps:

1. Select **Advanced Features**.

CF CLI Connection Timeout

15

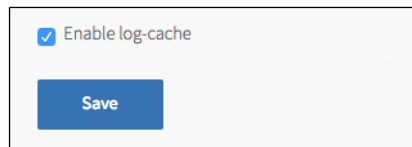

2. Add a value, in seconds, to the **CF CLI Connection Timeout** field.
3. Click **Save**.

Log Cache

Log Cache is an in-memory caching layer for logs and metrics. This Loggregator feature lets users filter and query logs through a CLI or API endpoints. Cached logs are available on demand. For more information about Log Cache, see [Enable Log Cache](#) in the *Configuring Logging in PASTopic*.

To configure the **Enable log-cache** checkbox, do the following:

1. Select **Advanced Features**.

A screenshot of a configuration panel. It contains a checkbox labeled 'Enable log-cache' which is checked. Below the checkbox is a blue button labeled 'Save'.

2. Select or deselect the **Enable log-cache** checkbox.
3. Click **Save**.

Database Connection Limits

You can configure the maximum number of concurrent database connections that diego and container networking components can have. Use the field beginning with **Maximum number of open connections...** for a given component. The placeholder values for each field are the default values.

When there are not enough connections available, such as during a time of heavy load, components may experience degraded performance and sometimes failure. To resolve or prevent this, you can increase and fine-tune database connection limits for the component.

⚠ warning: Decreasing the value of this field for a component may affect the amount of time it takes for it to respond to requests.

Step 21: Configure Errands

Errands are scripts that Ops Manager runs automatically when it installs or uninstalls a product, such as a new version of Pivotal Application Service (PAS). There are two types of errands: *post-deploy errands* run after the product is installed, and *pre-delete errands* run before the product is uninstalled.

By default, Ops Manager always runs all errands.

The PAS tile **Errands** pane lets you change these run rules. For each errand, you can select **On** to run it always or **Off** to never run it.

For more information about how Ops Manager manages errands, see the [Managing Errands in Ops Manager](#) topic.

💡 Note: Several errands, such as App Autoscaler and Notifications, deploy apps that provide services for your deployment. When one of these apps is running, selecting **Off** for the corresponding errand on a subsequent installation does not stop the app.

- **Smoke Test Errand** verifies that your deployment can do the following:
 - Push, scale, and delete apps
 - Create and delete orgs and spaces
- **Usage Service Errand** deploys the Pivotal Usage Service application, which Apps Manager depends on.
- **Apps Manager Errand** deploys Apps Manager, a dashboard for managing apps, services, orgs, users, and spaces. Until you deploy Apps Manager, you must perform these functions through the cf CLI. After Apps Manager has been deployed, Pivotal recommends setting this errand to **Off** for subsequent PAS deployments. For more information about Apps Manager, see the [Getting Started with the Apps Manager](#) topic.
- **Notifications Errand** deploys an API for sending email notifications to your PCF platform users.

💡 Note: The Notifications app requires that you [configure SMTP](#) with a username and password, even if you set the value of **SMTP Authentication Mechanism** to `none`.

- **Notifications UI Errand** deploys a dashboard for users to manage notification subscriptions.
- **App Autoscaler Errand** enables you to configure your apps to automatically scale in response to changes in their usage load. See the [Scaling an Application Using Autoscaler](#) topic for more information.
- **NFS Broker Errand** enables you to use NFS Volume Services by installing the NFS Broker app in PAS. See the [Enabling NFS Volume Services](#) topic for more information.

Step 22: (Optional) Disable Unused Resources

💡 Note: The **Resource Config** pane has fewer VMs if you are installing the [Small Footprint Runtime](#).

Note: The Small Footprint Runtime does not default to a highly available configuration. It defaults to the minimum configuration. If you want to make the Small Footprint Runtime highly available, scale the **Compute**, **Router**, and **Database** VMs to **3** instances and scale the **Control** VM to **2** instances.

Pivotal Application Service (PAS) defaults to a highly available resource configuration. However, you may need to perform additional procedures to make your deployment highly available. See the [Zero Downtime Deployment and Scaling in CF](#) and the [Scaling Instances in PAS](#) topics for more information.

If you do not want a highly available resource configuration, you must scale down your instances manually by navigating to the **Resource Config** section and using the dropdowns under **Instances** for each job.

By default, PAS also uses an internal filestore and internal databases. If you configure PAS to use external resources, you can disable the corresponding system-provided resources in Ops Manager to reduce costs and administrative overhead.

To disable specific VMs in Ops Manager, do the following:

1. Click **Resource Config**.
2. If you configured PAS to use an external S3-compatible filestore, enter **0** in **Instances** in the **File Storage** field.
3. If you selected **External** when configuring the UAA, System, and CredHub databases, edit the following fields:
 - MySQL Proxy: Enter **0** in **Instances**.
 - MySQL Server: Enter **0** in **Instances**.
 - MySQL Monitor: Enter **0** in **Instances**.
4. If you disabled TCP routing, enter **0** **Instances** in the **TCP Router** field.
5. If you are not using HAProxy, enter **0** **Instances** in the **HAProxy** field.
6. Click **Save**.

Step 23: Download Stemcell

This step is only required if your Ops Manager does not already have the stemcell version required by PAS. For more information about importing stemcells, see [Importing and Managing Stemcells](#).

1. Open the [Stemcell product page](#) in the Pivotal Network. *Note, you may have to log in.*
2. Download the appropriate stemcell version targeted for your IaaS.
3. Navigate to **Stemcell Library** in the **Installation Dashboard**.
4. Click **Import Stemcell** to import the downloaded stemcell **.tgz** file.
5. When prompted, enable the Ops Manager product checkbox to stage your stemcell.
6. Click **Apply Stemcell to Products**.

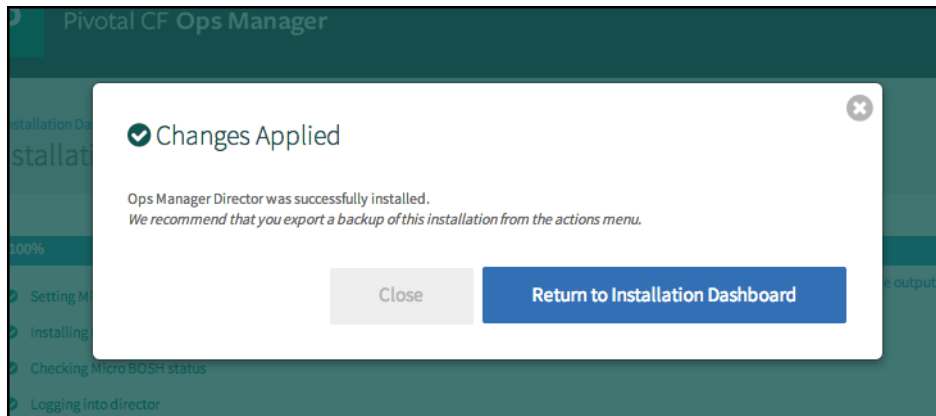

Step 24: Complete the PAS Installation

1. Click the **Installation Dashboard** link to return to the Installation Dashboard.
2. Click **Apply Changes**. If the following ICMP error message appears, click **Ignore errors and start the install**.

The install process generally requires a minimum of 90 minutes to complete. The image shows the Changes Applied window that displays when the

installation process successfully completes.

Deploying PAS with NSX-T Networking

Page last updated:

This topic describes how to install Pivotal Application Service (PAS) on vSphere with NSX-T internal networking, using the VMware NSX-T Container Plug-in for PCF.

Overview

PAS v2.0 uses a Container Network Interface (CNI) plugin to support secure and direct internal communication between containers. This plugin can be:

- The internal Silk plugin that comes packaged with PAS, or
- On vSphere, [VMware NSX-T Container Plug-in for PCF](#), which installs as an Ops Manager tile.

Prerequisites

Before deploying PAS with NSX-T networking, you must have the following:

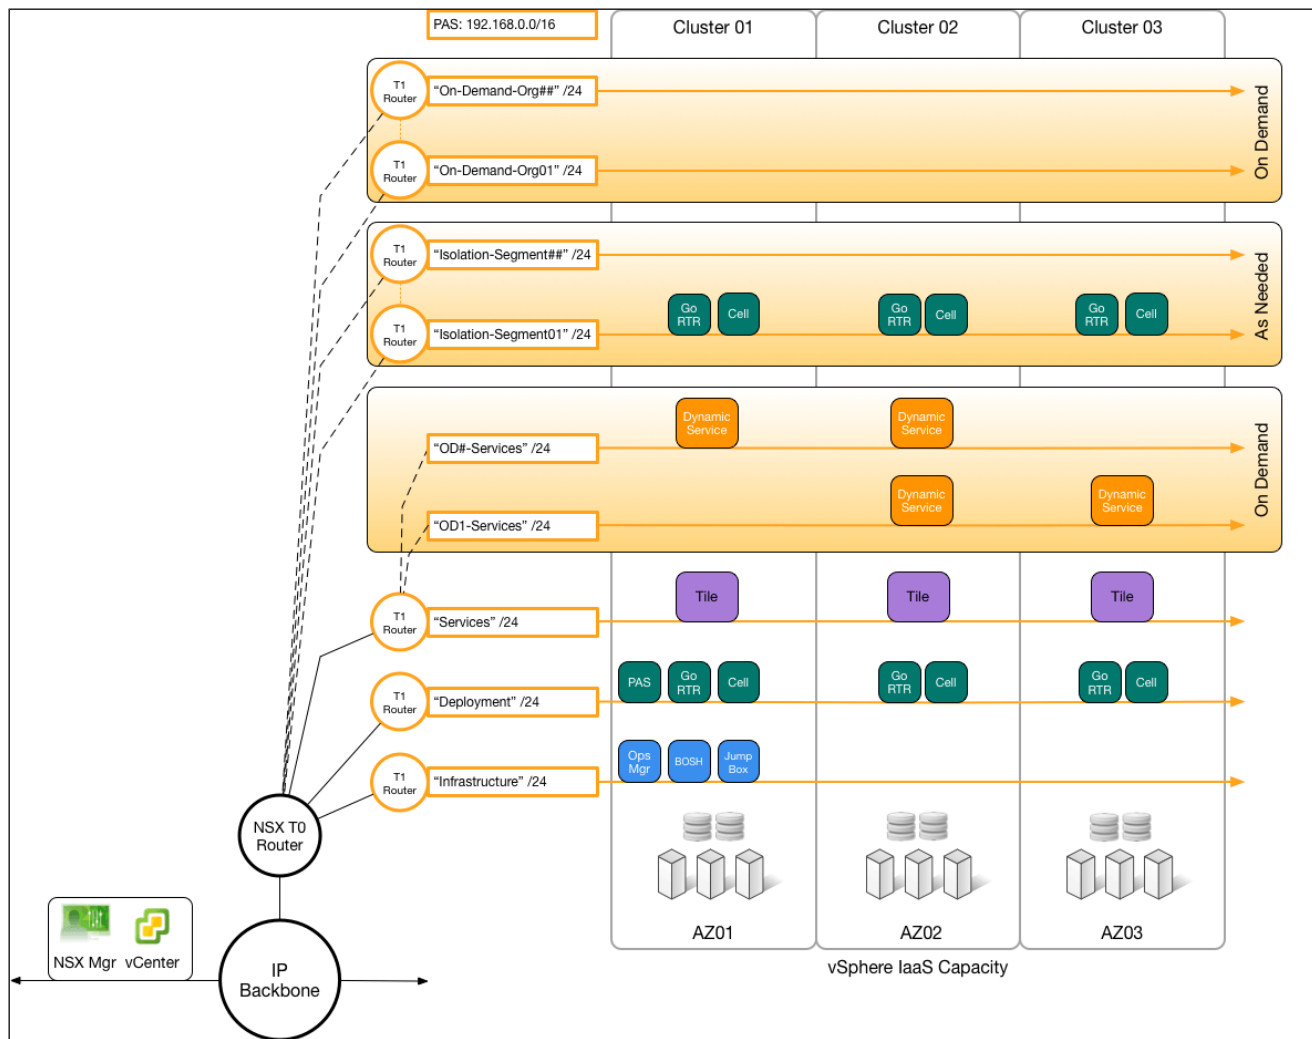

- An NSX-T 2.2 or later environment with NSX-T components installed and configured. See the [NSX-T Cookbook](#) for directions.
- BOSH and Ops Manager v2.3 or later installed and configured on vSphere. See [Deploying Ops Manager on vSphere](#) and [Configuring BOSH Director on vSphere](#).
- The [VMware NSX-T Container Plug-in for PCF tile](#) downloaded from Pivotal Network and imported to the Ops Manager **Installation Dashboard**. See [Adding and Importing Products](#) for how to download and import Pivotal products to the **Installation Dashboard**.
- The [PAS tile](#) downloaded from Pivotal Network and imported to the Ops Manager **Installation Dashboard**. The PAS tile must be in one of the following two states:
 - Not deployed yet; you have not yet run **Apply Changes** on this version of PAS.
 - Deployed previously, with the **Networking** pane > **Container Network Interface Plugin** set to **External**.

Note: Deploying PAS with its Container Network Interface (CNI) set to **Silk** configures Diego cells to use an internally-managed container network. Subsequently switching the CNI interface to **External** NSX-T leads to errors.

Architecture

The following diagram shows how to deploy an NSX-T machine to run PAS across multiple vSphere hardware clusters. NSX-T runs a Tier-0 (T0) router and multiple Tier-1 (T1) routers, each connecting to a network within Pivotal Cloud Foundry. Each vSphere hardware column cluster corresponds to an Availability Zone in PCF:

When a developer pushes an app to a new Org for the first time, the NSX-T plugin triggers NSX-T to create a new T1 router and allocate an address range for the Org, on demand.

Install and Configure PAS and NSX-T

Installing NSX-T to run with PAS requires the following actions, which are described below:

1. [Set up NSX-T to Integrate with PAS](#)
2. [Enable NSX-T Mode in the BOSH Director](#)
3. [Configure PAS for External Container Networking](#)
4. [Install and Configure the NSX-T Tile](#)

Set up NSX-T to Integrate with PAS

1. In vSphere, create logical network switches to correspond to the networks that PCF uses.
 - a. Log into the **NSX Manager Dashboard**.
 - b. Open the **Switching** tab.
 - c. For each of these networks...
 - **Infrastructure** (BOSH and Ops Manager, defined in BOSH Director tile > **Assign AZs and Networks** pane)
 - **Deployment** (PAS, defined in PAS tile > **Assign AZs and Networks** pane)
 - **Services and Dynamic Services** (marketplace services and on-demand services, also defined in the PAS tile)
 - **Isolation Segment** (optional, defined in the Isolation Segment tile > **Assign AZs and Networks** pane)

...do the following:

1. Click **Add New Logical Switch**.
2. Enter a name for the logical switch (e.g. `infrastructure-ls`, `deployment-ls`).

Add New Logical Switch

General Switching Profiles

Name * infrastructure-ls

Description

Transport Zone * tz-overlay

Admin Status ☒ Up

Replication Mode ☒ Hierarchical Two-Tier replication ☐ Head replication

VLAN *

SAVE **CANCEL**

3. Click **Save**.

2. Create T0 network address translation (NAT) rules to facilitate communication between Ops Manager and the BOSH Director.

- a. Create and configure a T0 router and router port for PCF.
- b. In NSX Manager, select your T0 Router and navigate to **Services > NAT**.
- c. Add a rule for destination NAT (DNAT) with:
 - The externally-specified destination IP address of incoming requests
 - The internal network address to translate the external address to

New NAT Rule

Priority 1024

Action * DNAT

Protocol ☒ Any Protocol ☐ Specific Protocol

Destination IP * 10.193.253.65

Translated IP * 192.168.1.10

Translated Ports

Status ☒ Enabled

Logging ☐ Disabled

Firewall Bypass ☒ Enabled

SAVE **CANCEL**

- d. Add a rule for source NAT (SNAT) with:

- The range of internal addresses that outgoing traffic may come from

- The external IP address to put in each outgoing packet header, indicating its source

3. Create T1 Routers for PAS, to connect from the T0 router. For each PCF network, Infrastructure, Deployment, and so on, create a T1 router as follows:

- In the NSX Manager UI, navigate to **Routing > Routers**
- Click **Add > Tier-1 Router**.
- Configure the router. For example, the Infrastructure network router configuration might look like:

New Tier-1 Router

Tier-1 Router

Advanced

Name *

infrastructure-t1

Description

Tier-0 Router

router-t0

Failover Mode

☒ Preemptive
 ☐ Non-Preemptive

Edge Cluster

edge-cluster-01

Edge Cluster Members ⓘ

Preferred Member ⓘ

SAVE

CANCEL

4. Create T1 router ports for PAS. For each T1 router you created, add a **New Router Port** as follows, to allow traffic in and out:

- In the NSX Manager UI, select the T1 router.
- In **Configuration > Router Ports**, add a new router port.
- For **Logical Switch**, enter the name of the logical switch you defined for the network in **Add New Logical Switch**, above.

New Router Port

Name *

Description

5. Advertise the routes of the T1 routers to the T0 router, so the T0 router can correctly route incoming requests based on their destination IP address:

- Select your T1 Router and navigate to **Routing > Route Advertisement**.
- Under **Edit Route Advertisement Configuration**, enable route advertisement by setting **Status** to **Enabled**.
- Set **Advertise All NSX Connected Routes** to **Yes**.
- If you are using NSX-T Load Balancers to route traffic, set **Advertise All LB VIP Routes** and **Advertise All LB SNAT IP Routes** to **Yes**.

Edit Route Advertisement Configuration

6. Allocate an IP Block for PAS Orgs.

- From NSX Manager, navigate to **DDI > IPAM > New IP block**.

- b. Enter a description, such as `This is where IP addresses come from when a new Org is created in PAS.`
- c. Enter a CIDR to allocate an address block large enough to accommodate all PAS apps.

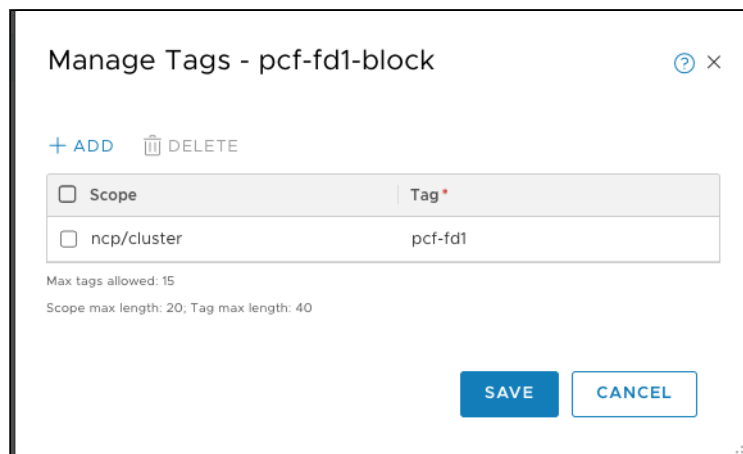

New IP Block ⓘ ×

Name *

Description

CIDR *

Max tags allowed: 15
Scope max length: 20; Tag max length: 40

- d. Add a tag to the newly-created IP block.

7. Create a new switching profile with the following fields and tags:

- **Name:** `ncp-ha`
- **Type:** `Spoof Guard`
- **Tags:** Add a tag with **Scope** `ncp/ha`, **Tag** `True`
- **Tags:** Add a second tag with the **Scope** and **Tag** name of the T0 router tag you defined above.

-----END CERTIFICATE-----
```

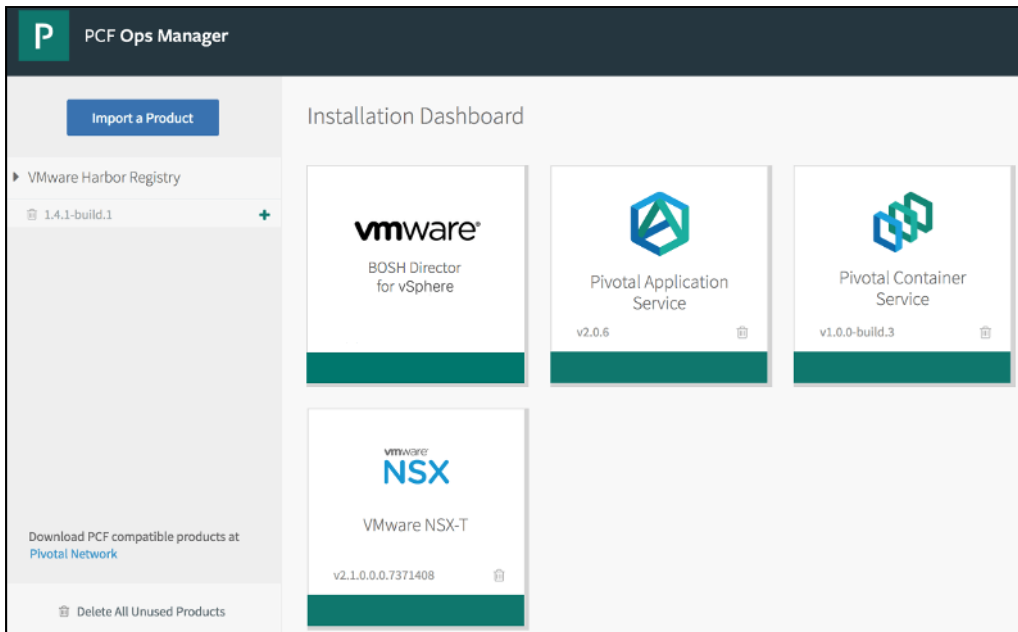

3. Configure NSX networking by entering the following:

- **NSX Mode:** Select **NSX-T**.
- **NSX Address:** Enter the address of the NSX Manager.
- **NSX Username:** Enter the username to connect to the NSX Manager.
- **NSX Password:** The password for the username specified above.
- **NSX CA Cert:** A CA certificate in PEM format that authenticates to the NSX server. If the NSX Manager generated a self-signed certificate, you can retrieve the CA certificate using OpenSSL with the command `openssl s_client -host NSX-ADDRESS -port 443 -prexit -showcerts`.

 **Note:** To update NSX security group and load balancer information, see the [Updating NSX Security Group and Load Balancer Information](#) topic.

Configure PAS for External Container Networking

1. If you have not already done so, download the PAS tile from [Pivotal Network](#) and import it to the **Installation Dashboard**. See [Adding and Importing Products](#) for directions.

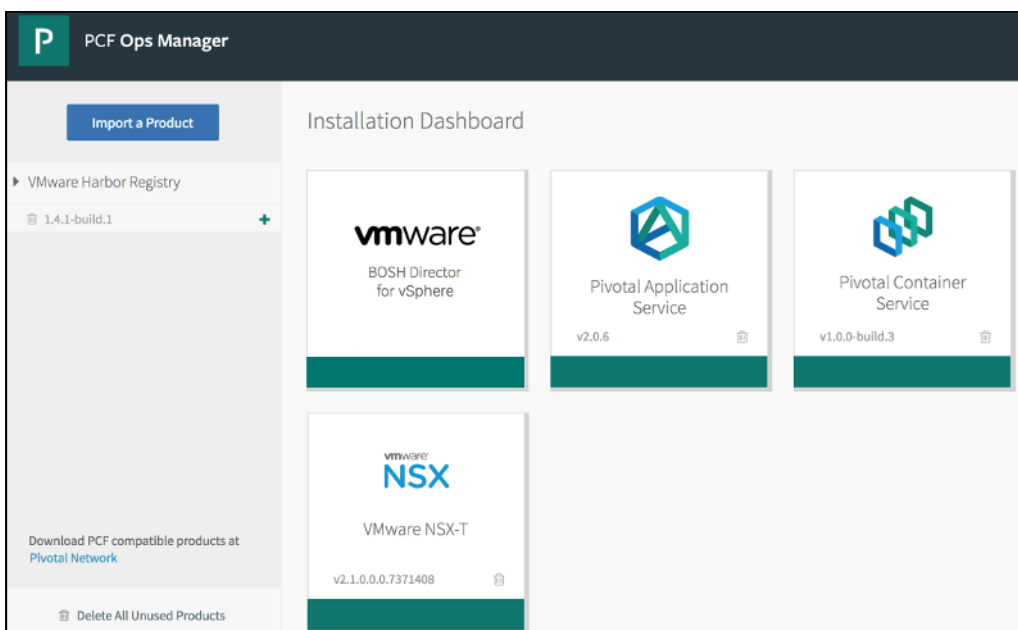

2. Configure PAS, following the directions in [Deploying PAS on vSphere](#). When you configure **Networking**, select **External** under **Container Networking Interface Plugin**.

Install and Configure the NSX-T tile

1. If you have not already done so, download the VMware NSX-T tile from [Pivotal Network](#) and import it to the **Installation Dashboard**. See [Adding and Importing Products](#) for directions.

2. Click the **VMware NSX-T** tile to open its **Settings** tab, and configure the **NSX Manager** pane as follows:
 - **NSX Manager Address:** NSX Manager host address or IP address
 - **Use Client Certificates or Username/Password:** Select **Basic Authentication with Username and Password** and enter **NSX Manager Admin Username** and **Admin Password** credentials in the fields underneath.
 - **NSX Manager CA Cert:** Obtain this certificate from NSX Manager as follows:

1. `ssh` into NSX Manager using the admin account that you created when you deployed NSX Manager.
2. From the NSX Manager command line, run `get certificate api` to retrieve the certificate.

The screenshot shows the VMware NSX-T Installation Dashboard. The top navigation bar includes 'Installation Dashboard', 'Settings', 'Status', 'Credentials', and 'Logs'. The left sidebar shows a list of components: NSX Manager (checked), NCP (checked), and NSX Node Agent (checked). The main content area is titled 'NSX Manager Configuration'. It contains the following fields and options:

- NSX Manager Address ***: A text input field containing 'nsx-manager.haas-108.pez.pivotal.io'.
- Use Client Certificates or Username/Password for NSX Manager Authentication ***: Two radio button options. 'Client Certificate Authentication' is unselected, and 'Basic Authentication with Username and Password' is selected.
- NSX Manager Admin Username ***: A text input field containing 'admin'. A label 'Admin username of NSX Manager' is to the right.
- NSX Manager Admin Password ***: A password input field with masked characters '*****'. A 'Change' link is below the field.
- NSX Manager CA Cert**: A text input field containing '-----BEGIN CERTIFICATE-----'.

3. Open and configure the **NCP** (NSX-T Container Plugin) pane as follows:

- **PAS Foundation Name**: The tag string you gave to the `t0 router` in NSX Manager, above.
- **Overlay Transport Zone**: A uniquely identifying string for the **Transport Zone** that you chose when you [created logical switches](#) for each network. This can be the name of the transport zone if no other zones in NSX share the same name, or else the UUID for the transport zone.
- **Tier-0 Router**: A uniquely identifying string for the T0 router. This can be the tag string that you gave the router in NSX Manager if no other T0 routers in NSX share the same name, or else the UUID for the router.
- **Subnet Prefix of Container Networks**: Subnet mask to set the address range size for apps in a single org. Defaults to `24`. This number must be higher than the mask for all PAS orgs in the NSX Manager **New IP Block** pane, to define a each Org's fraction of the total PAS address space.
- **Enable SNAT for Container Network**: Enable this checkbox.

NCP Configuration

PAS Foundation Name *

Overlay Transport Zone *

This string uniquely identifies the NSX overlay transport zone for logical switches for container networking. You can specify the name or the UUID of the transport zone to be used.

Tier-0 Router *

IP Blocks of Container Networks

☒ Enable Debug Level of Logging for NSX Node Agent

Save

- Click **Save** and return to the **Installation Dashboard**.
- After you have configured both the **PAS** tile and the **VMware NSX-T** tile, click **Apply Changes** to deploy PAS with NSX-T networking.

Automation

- [Concourse Pipelines: Configure NSX-T for PAS](#) : This sample Concourse pipeline provides jobs setup switches, routers, an IP block, and an IP pool to be used by PAS.
- [PyNSXT](#) : This is a Python library that can be used as a CLI to run commands against a VMWare NSX-T installation. It exposes operations for working with logical switches, logical routers, and pools. It uses version 2.1 of NSX-T for the swagger client.

vSphere Virtual Disk Types

Page last updated:

When you create a virtual machine in VMware vSphere, vSphere creates a new virtual hard drive for that virtual machine. The virtual hard drive is contained in a virtual machine disk (VMDK). The disk format you choose for the new virtual hard drive can have a significant impact on performance.

You can choose one of three formats when creating a virtual hard drive:

- Thin Provisioned
- Thick Provisioned Lazy Zeroed
- Thick Provisioned Eager Zeroed

Thin Provisioned

Advantages:

- Fastest to provision
- Allows disk space to be overcommitted to VMs

Disadvantages:

- Slowest performance due to metadata allocation overhead and additional overhead during initial write operations
- Overcommitment of storage can lead to application disruption or downtime if resources are actually used
- Does not support clustering features

When vSphere creates a thin provisioned disk, it only writes a small amount of metadata to the datastore. It does not allocate or zero out any disk space. At write time, vSphere first updates the allocation metadata for the VMDK, then zeros out the block or blocks, then finally writes the data. Because of this overhead, thin provisioned VMDKs have the lowest performance of the three disk formats.

Thin provisioning allows you to overcommit disk spaces to VMs on a datastore. For example, you could put 10 VMs, each with a 50 GB VMDK attached to it, on a single 100 GB datastore, as long as the sum total of all data written by the VMs never exceeded 100 GB. Thin provisioning allows administrators to use space on datastores that would otherwise be unavailable if using thick provisioning, possibly reducing costs and administrative overhead.

Thick Provisioned Lazy Zeroed

Advantages:

- Faster to provision than Thick Provisioned Eager Zeroed
- Better performance than Thin Provisioned

Disadvantages:

- Slightly slower to provision than Thin Provisioned
- Slower performance than Thick Provisioned Eager Zero
- Does not support clustering features

When vSphere creates a thick provisioned lazy zeroed disk, it allocates the maximum size of the disk to the VMDK, but does nothing else. At the initial access to each block, vSphere first zeros out the block, then writes the data. Performance of a thick provisioned lazy zeroed disk is not as good a thick provisioned eager zero disk because of this added overhead.

Thick Provisioned Eager Zeroed

Advantages:

- Best performance
- Overwriting allocated disk space with zeros reduces possible security risks
- Supports clustering features such as Microsoft Cluster Server (MSCS) and VMware Fault Tolerance

Disadvantages:

- Longest time to provision

When vSphere creates a thick provisioned eager zeroed disk, it allocates the maximum size of the disk to the VMDK, then zeros out all of that space.

Example: If you create an 80 GB thick provisioned eager zeroed VMDK, vSphere allocates 80 GB and writes 80 GB of zeros.

By overwriting all data in the allocated space with zeros, thick provisioned eager zeroed eliminates the possibility of reading any residual data from the disk, thereby reducing possible security risks.

Thick provisioned eager zeroed VMDKs have the best performance. When a write operation occurs to a thick provisioned eager zeroed disk, vSphere writes to the disk, with none of the additional overhead required by thin provisioned or thick provisioned lazy zeroed formats.

Using the Cisco Nexus 1000v Switch with Ops Manager

Page last updated:

Refer to the procedure in this topic to use Ops Manager with the Cisco Nexus 1000v Switch. First, configure Ops Manager through Step 4 in [Configuring BOSH Director on vSphere](#). Then configure your network according to the following steps.

1. From your [Pivotal Cloud Foundry](#) (PCF) Ops Manager **Installation Dashboard**, click the **BOSH Director** tile.
2. Select **Create Networks**.
3. Click the network name to configure the network settings. This is **default** if you have not changed the name.

Using BOSH Resurrector and vSphere HA

Page last updated:

This topic describes the BOSH Resurrector and vSphere High Availability (HA), as well as how to enable them for your Pivotal Cloud Foundry (PCF) deployment.

Pivotal recommends BOSH Resurrector, vSphere HA, and a highly-available storage solution to protect the VMs in your deployment.

BOSH Resurrector

The following sections describe the BOSH Resurrector and how to enable it.

About BOSH Resurrector

The BOSH Resurrector increases Pivotal Application Service (PAS) availability in the following ways:

- Reacts to hardware failure and network disruptions by recreating virtual machines on active, stable hosts
- Detects operating system failures by continuously monitoring virtual machines and recreating them as required
- Continuously monitors the BOSH Agent running on each virtual machine and recreates the VMs as required

The BOSH Resurrector continuously monitors the status of all virtual machines in an PAS deployment. The Resurrector also monitors the BOSH Agent on each VM. If either the VM or the BOSH Agent fail, the Resurrector recreates the virtual machine on another active host.

BOSH Resurrector Limitations

The following limitations apply to using the BOSH Resurrector:

- The Resurrector does not monitor or protect the Ops Manager VM or the BOSH Director VM.
- The Resurrector might not be able to resolve issues caused by the loss of an entire host.
- The Resurrector does not monitor or protect data storage.

To mitigate these limitations, Pivotal recommends vSphere HA. For more information, see [vSphere HA](#) below.

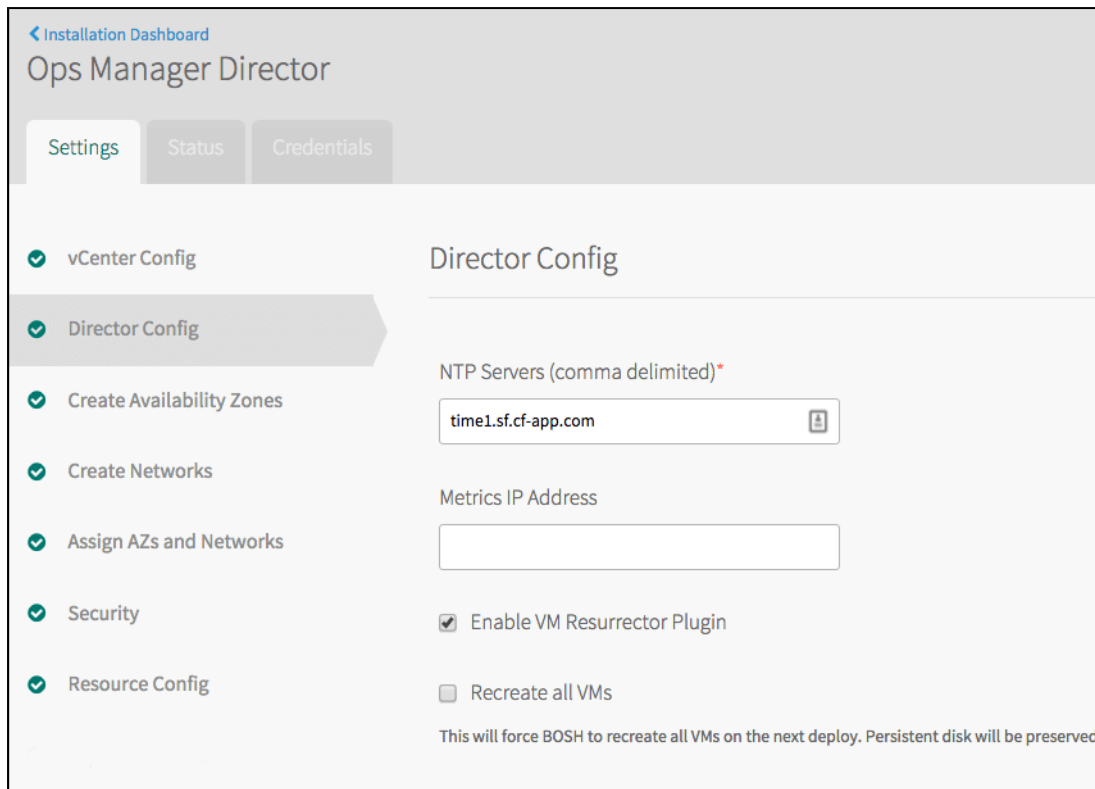

Enable BOSH Resurrector

To enable the BOSH Resurrector:

1. Log into the Ops Manager web interface.
2. On the Product Dashboard, select **BOSH Director**.

3. In the left navigation menu, select **Director Config**.

4. Select **Enable VM Resurrector Plugin** and click **Save**.

vSphere HA

The following sections describe vSphere HA and how to enable it.

About vSphere HA

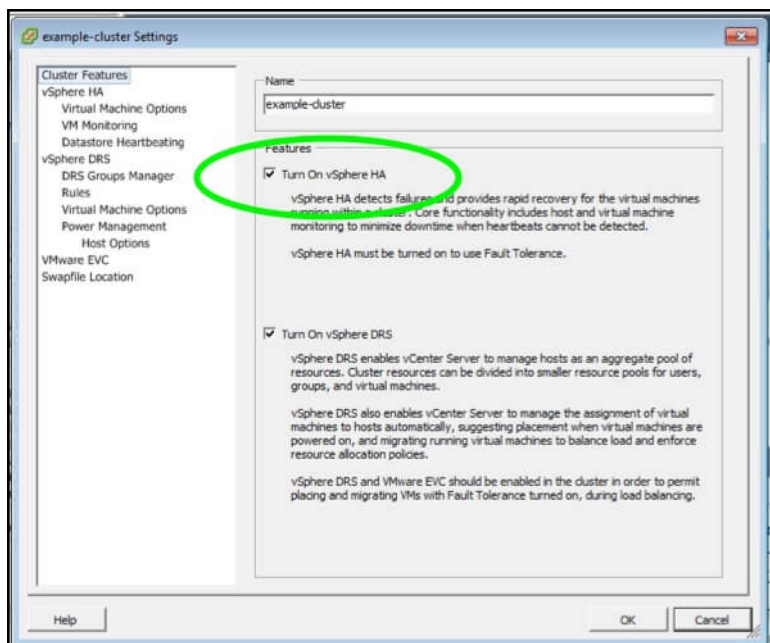

In the event of a host failure, vSphere HA restarts but does not recreate VMs on alternate ESXi hosts in the same cluster. A host failure could result from a sudden power off, crash due to hardware fault, or the vSphere host becoming disconnected from the network. BOSH Resurrector cannot recover from a host failure.

For more information, see [vSphere High Availability](#) in the BOSH documentation.

Enable vSphere HA

Follow the steps below to enable vSphere High Availability:

1. Launch the vSphere Management Console.
2. Right-click the cluster that contains the [Pivotal Cloud Foundry](#) deployment and select **Edit Settings**.
3. Select the **Turn on vSphere High Availability** checkbox.

4. Click **OK** to enable vSphere High Availability on the cluster.

Configuring Pivotal Cloud Foundry SSL Termination for vSphere Deployments

Page last updated:

To use SSL termination in [Pivotal Cloud Foundry](#) (PCF), you must configure the Pivotal-deployed HAProxy load balancer or your own load balancer.

Pivotal recommends that you use HAProxy in lab and test environments only. Production environments should instead use a highly-available customer-provided load balancing solution.

Select an SSL termination method to determine the steps you must take to configure Pivotal Application Service (PAS).

Using the Pivotal HAProxy Load Balancer

PCF deploys with a single instance of HAProxy for use in lab and test environments. You can use this HAProxy instance for SSL termination and load balancing to the PCF Routers. HAProxy can generate a self-signed certificate if you do not want to obtain a signed certificate from a well-known certificate authority.

 **Note:** Certificates generated in PAS are signed by the Operations Manager Certificate Authority. They are not technically self-signed, but they are referred to as “Self-Signed Certificates” in the Ops Manager GUI and throughout this documentation.

To use the HAProxy load balancer, you must create a wildcard A record in your DNS and configure three fields in the PAS product tile.

1. Create an A record in your DNS that points to the HAProxy IP address. The A record associates the **System Domain** and **Apps Domain** that you configure in the **Domains** section of the PAS tile with the HAProxy IP address.

For example, with `cf.example.com` as the main subdomain for your CF install and an HAProxy IP address `203.0.113.1`, you must create an A record in your DNS that serves `example.com` and points `*.cf` to `203.0.113.1`.

| Name | Type | Data | Domain |
|------|------|-------------|-------------|
| *.cf | A | 203.0.113.1 | example.com |

2. Use the Linux `host` command to test your DNS entry. The `host` command should return your HAProxy IP address.

Example:

```
$ host cf.example.com
cf.example.com has address 203.0.113.1
$ host anything.example.com
anything.cf.example.com has address 203.0.113.1
```

3. From the PCF Ops Manager Dashboard, click on the PAS tile.
4. Select **Networking**.
5. Leave the **Router IPs** field blank. HAProxy assigns the router IPs internally.
6. Enter the IP address for HAProxy in the **HAProxy IPs** field.
7. Provide your SSL certificate in the **SSL Termination Certificate and Private Key** field. See [Providing a Certificate for your SSL Termination Point](#) for details.

[Return to the Getting Started Guide](#)

Using Another Load Balancer

Production environments should use a highly-available customer-provided load balancing solution that does the following:

- Provides SSL termination with wildcard DNS location
- Provides load balancing to each of the PCF Router IPs

- Adds appropriate `x-forwarded-for` and `x-forwarded-proto` HTTP headers

You must register static IP addresses for PCF with your load balancer and configure three fields in the PAS product tile.

1. Register one or more static IP address for PCF with your load balancer.
2. Create an A record in your DNS that points to your load balancer IP address. The A record associates the **System Domain** and **Apps Domain** that you configure in the **Domains** section of the PAS tile with the IP address of your load balancer.

For example, with `cf.example.com` as the main subdomain for your CF install and a load balancer IP address `198.51.100.1`, you must create an A record in your DNS that serves `example.com` and points `*.cf` to `198.51.100.1`.

| Name | Type | Data | Domain |
|------|------|--------------|-------------|
| *.cf | A | 198.51.100.1 | example.com |

3. From the PCF Ops Manager Dashboard, click on the PAS tile.
4. Select **Networking**.
5. In the **Router IPs** field, enter the static IP address for PCF that you have registered with your load balancer.
6. Leave the **HAProxy IPs** field blank.
7. Provide your SSL certificate in the **SSL Termination Certificate and Private Key** field. See [Providing a Certificate for your SSL Termination Point](#) for details.

 **Note:** When adding or removing PCF routers, you must update your load balancing solution configuration with the appropriate IP addresses.

[Return to the Installing Pivotal Cloud Foundry Guide](#) 

Availability Zones in vSphere

Page last updated:

This topic describes availability zones (AZs) in vSphere and an example of how an operator might scale an app across AZs.

Overview

Pivotal defines an AZ as an operator-assigned, functionally-independent segment of network infrastructure. In cases of partial infrastructure failure, a tile distributes and balances all instances of running apps across remaining AZs. Strategic use of Availability Zones contributes to the fault tolerance and high availability of a tile deployment.

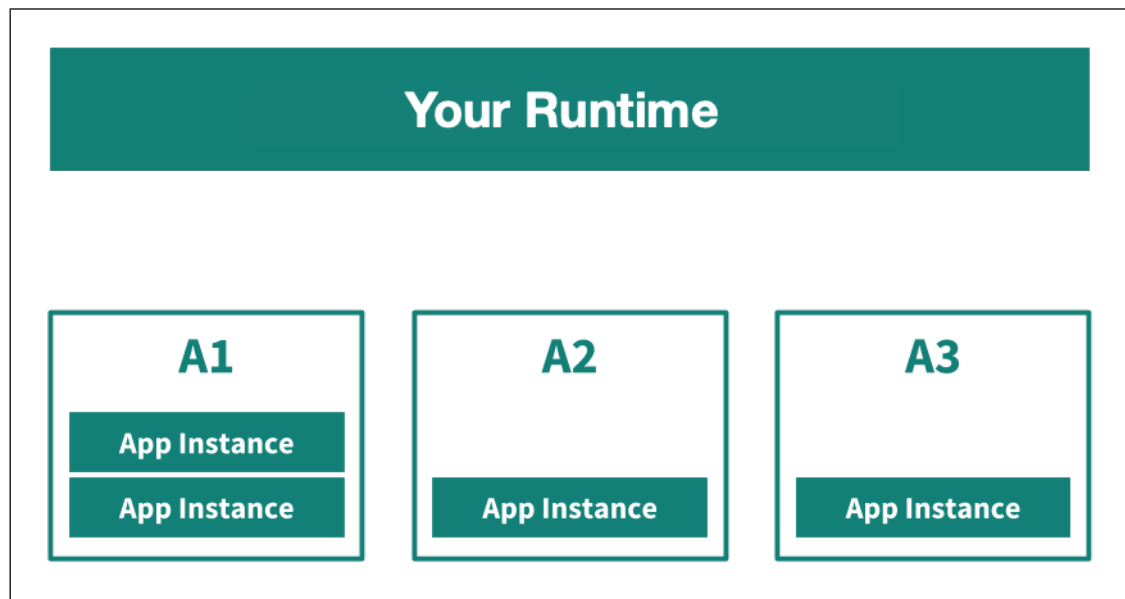

vSphere supports distributing deployments across multiple AZs. For more information, see *Step 4: Create Availability Zones* in [Configuring BOSH Director on vSphere](#).

It is recommended that customers use three Availability Zones to operate a highly available tile deployment.

Balancing Across AZs During Failure: Example Scenario

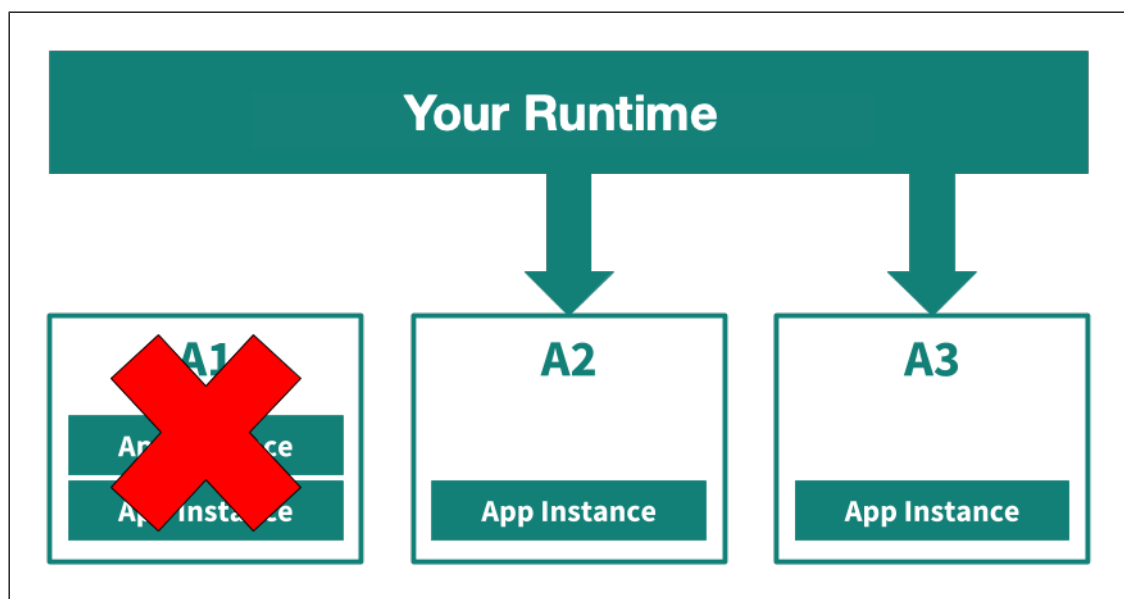

An operator scales an app to four instances in a tile environment distributed across three availability zones: A1, A2, and A3. The environment allocates the instances according to the [Diego Auction](#).

For a visual representation of this scenario, see the following diagram:

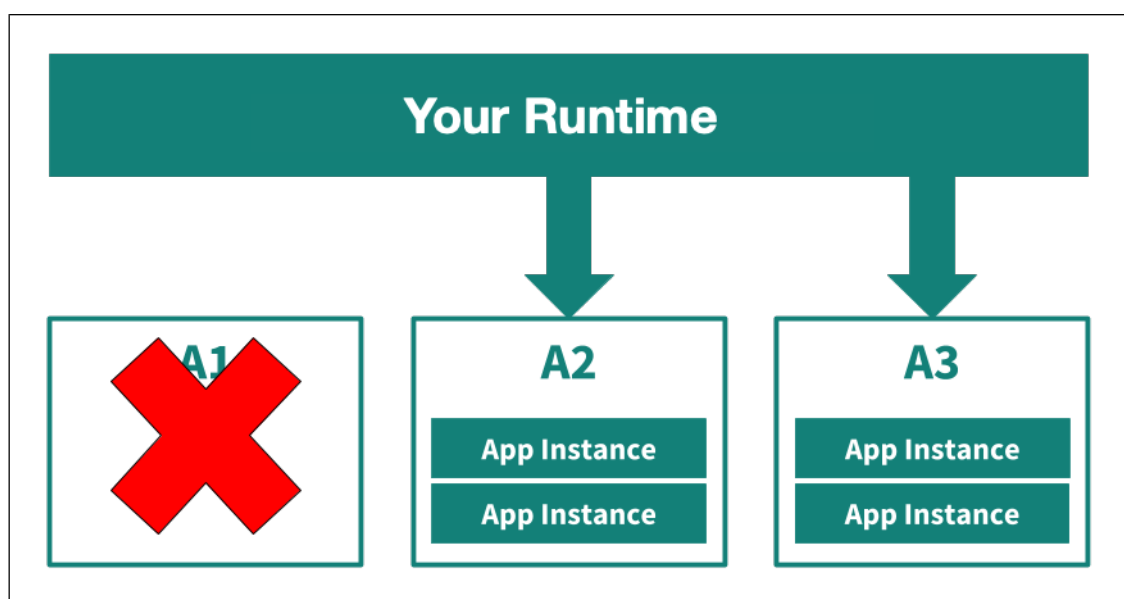

If A1 experiences a power outage or hardware failure, the two app instances running in A1 terminate while the app instances in zones A2 and A3 continue to run.

For a visual representation of this scenario, see the following diagram:

If A1 remains unavailable, the tile balances new instances of the app across the remaining availability zones.

For a visual representation of this scenario, see the following diagram:

Updating NSX Security Group and Load Balancer Information

Page last updated:

This topic describes how to update security group and load balancer information for Pivotal Cloud Foundry (PCF) deployments using NSX-V on vSphere. To update this information, you must use the Ops Manager API.

See the [Ops Manager API documentation](#) for more information about the API.

See [Using Edge Services Gateway on VMware NSX](#) for guidance on how to configure the NSX firewall, load balancing, and NAT/SNAT services for PCF on vSphere installations.

 **Note:** Ops Manager v1.11 supports NSX-V 6.2+.

Authenticate

To use the Ops Manager API, you must authenticate and retrieve a token from the Ops Manager User Account and Authentication (UAA) server. For instructions, see the [Using Ops Manager API](#) topic.

Update Security Group or Load Balancer Information

To update either NSX security group or load balancer information, you use `curl` to make a PUT request against the `api/v0/staged/products/product_guid/jobs/job_guid/resource_config` endpoint.

You must first retrieve the GUID of your PCF deployment, and the GUID of the job whose information you want to update.

Perform the following steps:

1. Retrieve a list of staged products:

```
$ curl 'https://OPS-MAN-FQDN/api/v0/staged/products' \
-H "Authorization: Bearer UAA-ACCESS-TOKEN"
[
  {
    "product_version": "1.10.6.0",
    "guid": "p-bosh-dee11e111e111e1e1a",
    "installation_name": "p-bosh",
    "type": "p-bosh"
  },
  {
    "type": "cf",
    "product_version": "1.10.8-build.7",
    "installation_name": "cf-01222ab1111111aaa1a",
    "guid": "cf-01222ab1111111aaa1a"
  }
]
```

Record the GUID of the `cf` product. In the above example, the GUID is `cf-01222ab1111111aaa1a`.

2. Retrieve a list of jobs for your product:

```
$ curl 'https://OPS-MAN-FQDN/api/v0/staged/products/PRODUCT-GUID/jobs' \
-H "Authorization: Bearer UAA-ACCESS-TOKEN"
{
  "jobs": [
    {
      "guid": "consul_server-9c37cf48ae7412f2afd1",
      "name": "consul_server"
    },
    {
      "name": "nats",
      "guid": "nats-6af18efdd18d198edee9"
    },
    {
      "name": "nfs_server",
      "guid": "nfs_server-b49b0b2aed247302e0e1"
    },
    ...
  ]
}
```

Record the GUID of the job whose security groups you want to update.

3. You can update either your security group information, load balancer information, or both.

- **Security groups:** To update the security groups for your job, use the following command:

```
$ curl "https://OPS-MAN-FQDN/api/v0/staged/products/PRODUCT-GUID/jobs/JOB-GUID/resource_config" \
-X PUT \
-H "Content-Type: application/json" \
-H "Authorization: Bearer UAA-ACCESS-TOKEN" \
-d '{"instance_type": {"id": "INSTANCE-TYPE"},
  "persistent_disk": {"size_mb": "DISK-SIZE"},
  "nsx_security_groups": ["SECURITY-GROUP1", "SECURITY-GROUP2"]}'
```

Replace the placeholder values as follows:

- **INSTANCE-TYPE** : The instance type for the job. For the default instance type, use `"automatic"`.
- **DISK-SIZE** : The disk size for the job. For the default persistent disk size, use `"automatic"`.

 **Note:** The `persistent_disk` parameter is required to make this API request. For jobs that do not have persistent disks, you must set the value of the parameter to `"automatic"`.

- **SECURITY-GROUP1** , **SECURITY-GROUP2** : The value of the `nsx_security_groups` parameter is a list of the security groups that you want to set for the job. To clear all security groups for a job, pass an empty list with the `[]` value.

- **Load balancers:** To update the load balancers for your job, use the following command:

```
$ curl "https://OPS-MAN-FQDN/api/v0/staged/products/PRODUCT-GUID/jobs/JOB-GUID/resource_config" \
-X PUT \
-H "Content-Type: application/json" \
-H "Authorization: Bearer UAA-ACCESS-TOKEN" \
-d '{"instance_type": {"id": "INSTANCE-TYPE"},
  "persistent_disk": {"size_mb": "DISK-SIZE"},
  "nsx_lbs": [
    {
      "edge_name": "EDGE-NAME",
      "pool_name": "POOL-NAME",
      "security_group": "SECURITY-GROUP",
      "port": "PORT-NUMBER"
    }
  ]
}'
```

Replace the placeholder values as follows:

- **INSTANCE-TYPE** : The instance type for the job. For the default instance type, use `"automatic"`.
- **DISK-SIZE** : The disk size for the job. For the default persistent disk size, use `"automatic"`.

 **Note:** The `persistent_disk` parameter is required to make this API request. For jobs that do not have persistent disks, you must set the value of the parameter to `"automatic"`.

- **EDGE-NAME** : The name of the NSX Edge.
- **POOL-NAME** : The name of the NSX Edge's server pool.
- **SECURITY-GROUP** : The name of the NSX server pool's target security group.
- **PORT** : The name of the port that the VM service is listening on, such as `5000`.

You can configure more than one load balancer for a job by using additional hashes in the `nsx_lbs` array.

4. Navigate to `OPS-MAN-FQDN` in a browser and log in to the Ops Manager Installation Dashboard.
5. Click **Apply Changes** to redeploy.

Installing PCF Isolation Segment

Page last updated:

This topic describes how to install the PCF Isolation Segment tile, which allows operators to isolate deployment workloads into dedicated resource pools called *isolation segments*.

Installing the tile installs a single isolation segment. However, you can install multiple isolation segments using the Replicator tool documented in [Step 4](#).

After installing the tile, you must perform the steps in the [Create an Isolation Segment](#) section of the *Managing Isolation Segments* topic to create the isolation segment in the Cloud Controller Database (CCDB). The topic also includes information about managing an isolation segment.

For more information about how isolation segments work, see [Isolation Segments](#).

Step 1: (Optional) Configure Routing

By default, the Pivotal Application Service (PAS) Router handles traffic for your isolation segment. However, you can deploy a dedicated router for your isolation segment instead. For information about configuring and managing routing for isolation segments, see the [Routing for Isolation Segments](#) topic.

To deploy a dedicated router, perform the following steps:

1. Add a load balancer in front of the PAS Router. The steps to do this depend on your IaaS, but the setup of the load balancer should mirror the setup of the load balancer for the PAS Router that you configured in the PAS tile.
2. Create a wildcard DNS entry for traffic routed to any app in the isolation segment. For example, `*.iso.example.com`.
3. Attach the wildcard DNS entry to the load balancer you created.

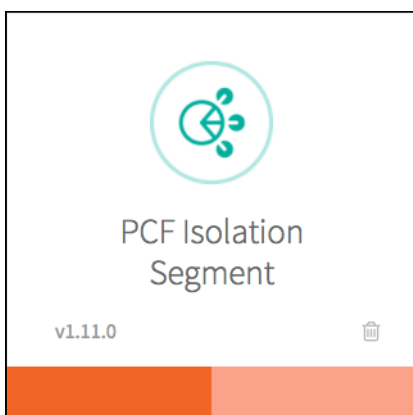

Step 2: Install the Tile

Perform the following steps to install the PCF Isolation Segment tile:

1. Download the product file from [Pivotal Network](#).
2. Navigate to `YOUR-OPSMAN-FQDN` in a browser to log in to the Ops Manager Installation Dashboard.
3. Click **Import a Product** and select the downloaded product file.
4. Under **PCF Isolation Segment** in the left column, click the plus sign.

Step 3: Configure the Tile

Click the orange **PCF Isolation Segment** tile to start the configuration process.

Assign AZs and Networks

Perform the following steps to configure the PCF Isolation Segment tile:

1. Click **Assign AZs and Networks**.

2. Select an availability zone for your singleton jobs, and one or more availability zones to balance other jobs in.
3. Select a network. This network does not need to be the same network where you deployed PAS. For most deployments, operators should create unique networks in which to deploy the Isolation Segment tile. These networks should maintain network reachability with the Diego components so that the cells can reach the Diego Brain and Diego Database VMs.
4. Click **Save**.

Networking

Perform the following steps to configure the PCF Isolation Segment tile:

1. Click **Networking**.

2. (Optional): Under **Router IPs**, enter one or more static IP addresses for the routers that handle this isolation segment. These IP addresses must be within the subnet CIDR block that you defined in the Ops Manager network configuration for your Isolation Segment. If you have a load balancer, configure it to point to these IP addresses.

Note: Entering the static IP addresses is not necessary for deployments running on a public IaaS such as AWS, GCP, or Azure because PCF users specify the IaaS load balancer in the **Resource Config** section of the **PCF Isolation Segment** tile.

- If you want to use HAProxy for this isolation segment, enter at least one address in the **HAProxy IPs** field. You should specify more than one IP address for high availability. Then configure your load balancer to forward requests for the domains you have set up for your deployment to these IP addresses. For more information, see [Configuring SSL/TLS Termination at HAProxy](#).

Note: If you rely on HAProxy for a feature in Pivotal Application Service (PAS) and you want isolated networking for this isolation segment, you may want to deploy the HAProxy provided by the Isolation Segment tile.

- Under **Certificates and Private Key for HAProxy and Router**, you must provide at least one **Certificate and Private Key** name and certificate keypair for HAProxy and Gorouter. The HAProxy and Gorouter are enabled to receive TLS communication by default. You can configure multiple certificates for HAProxy and Gorouter.
 - Click the **Add** button to add a name for the certificate chain and its private keypair. This certificate is the default used by Gorouter and HAProxy.

Certificates and Private Keys for HAProxy and Router

example-cert

Name *

example-cert

A human-readable name describing the use of this certificate.

Certificate and Private Key for HAProxy and Router *

```
-----BEGIN CERTIFICATE-----
MIIE...
-----END CERTIFICATE-----
-----BEGIN RSA PRIVATE KEY-----
...
-----END RSA PRIVATE KEY-----
```

[Generate RSA Certificate](#)

example-cert-2

Name *

example-cert-2

Certificate and Private Key for HAProxy and Router *

```
-----BEGIN CERTIFICATE-----
MIIE...
-----END CERTIFICATE-----
-----BEGIN RSA PRIVATE KEY-----
...
-----END RSA PRIVATE KEY-----
```

You can either provide a certificate signed by a Certificate Authority (CA) or click on the **Generate RSA Certificate** link to generate a self-signed certificate in Ops Manager.

- If you want to configure multiple certificates for HAProxy and Gorouter, click the **Add** button and fill in the appropriate fields for each additional certificate keypair.

For details about generating certificates in Ops Manager for your wildcard system domains, see the [Providing a Certificate for Your SSL/TLS Termination Point](#) topic.

Note: If you configured Ops Manager Front End without a certificate, you can use this new certificate to complete Ops Manager configuration. To configure your Ops Manager Front End certificate, see *Configure Front End* in [Preparing to Deploy Ops Manager on GCP Manually](#).

Note: Ensure that you add any certificates that you generate in this pane to your infrastructure load balancer.

- (Optional) When validating client requests using mutual TLS, the Gorouter trusts multiple certificate authorities (CAs) by default. If you want to

configure the Gorouter and HAProxy to trust additional CAs, enter your CA certificates under **Certificate Authorities Trusted by Router and HAProxy**. All CA certificates should be appended together into a single collection of PEM-encoded entries.

Certificate Authorities Trusted by Router and HAProxy

In addition to well-known, public CAs, and those trusted via the BOSH trusted certificates collection, these certificates can be used to validate the certificates from incoming client requests. All CA certificates should be appended together into a single collection of PEM-encoded entries.

- In the **Minimum version of TLS supported by HAProxy and Routerfield**, select the minimum version of TLS to use in HAProxy and Gorouter communications. HAProxy and Gorouter use TLS v1.2 by default. If you need to accommodate clients that use an older version of TLS, select a lower minimum version. For a list of TLS ciphers supported by the Gorouter, see [Securing Traffic into Cloud Foundry](#).

Minimum version of TLS supported by HAProxy and Router*

☐ TLSv1.0
☐ TLSv1.1
☒ TLSv1.2

- Configure **Logging of Client IPs in CF Router**. The **Log client IPs** option is set by default. To comply with the General Data Protection Regulation (GDPR), select one of the following options to disable logging of client IP addresses:

- If your load balancer exposes its own source IP address, disable logging of the `X-Forwarded-For` HTTP header only.
- If your load balancer exposes the source IP of the originating client, disable logging of both the source IP address and the `X-Forwarded-For` HTTP header.

Logging of Client IPs in CF Router*

☒ Log client IPs
☐ Disable logging of X-Forwarded-For header only
☐ Disable logging of both source IP and X-Forwarded-For header

To comply with GDPR, select one of the options to disable logging of client IPs. If the source IP exposed by your load balancer is its own, choose to disable logging of XFF header only. If the source IP exposed by your load balancer is that of the downstream client, choose to disable logging of the source IP also.

- Under **Configure support for the X-Forwarded-Client-Cert header**, configure PCF handles `x-forwarded-client-cert` (XFCC) HTTP headers based on where TLS is terminated for the first time in your deployment.

Configure support for the X-Forwarded-Client-Cert header. This header can be used by applications to verify the requester via mutual TLS. The option you should select depends upon where you will be terminating the TLS connection for the first time. *

☒ TLS terminated for the first time at infrastructure load balancer
☐ TLS terminated for the first time at HAProxy
☐ TLS terminated for the first time at the Router

The following table indicates which option to choose based on your deployment layout.

| If your deployment is configured as follows: | Then select the following option: | Additional notes: |
|--|--|---|
| <ul style="list-style-type: none"> The Load Balancer is terminating TLS, and Load balancer is configured to put the client certificate from a mutual authentication TLS handshake into the X-Forwarded-Client-Cert HTTP header | TLS terminated for the first time at infrastructure load balancer (default). | Both HAProxy and the Gorouter forward the XFCC header when included in the request. |
| | | HAProxy sets the XFCC header with the client certificate received in the |

| | | |
|--|---|--|
| <ul style="list-style-type: none"> ◦ The Load Balancer is configured to pass through the TLS handshake via TCP to the instances of HAProxy, and ◦ HAProxy instance count is > 0 | <p>TLS terminated for the first time at HAProxy.</p> | <p>TLS handshake. The Gorouter forwards the header.</p> <div>  Breaking Change: In the Router behavior for Client Certificates field, you cannot select the Router does not request client certificates option. </div> |
| <ul style="list-style-type: none"> ◦ The Load Balancer is configured to pass through the TLS handshake via TCP to instances of the Gorouter | <p>TLS terminated for the first time at the Gorouter.</p> | <p>The Gorouter strips the XFCC header if it is included in the request and forwards the client certificate received in the TLS handshake in a new XFCC header.</p> <p>If you have deployed instances of HAProxy, app traffic bypasses those instances in this configuration. If you have also configured your load balancer to route requests for ssh directly to the Diego Brain, consider reducing HAProxy instances to 0.</p> <div>  Breaking Change: In the Router behavior for Client Certificates field, you cannot select the Router does not request client certificates option. </div> |

For a description of the behavior of each configuration option, see [Forward Client Certificate to Applications](#).

9. To configure HAProxy to handle client certificates, select one of the following options in the **HAProxy behavior for Client Certificate Validation** field.

HAProxy behavior for Client Certificate Validation*

☒ HAProxy does not request client certificates.

☐ HAProxy requests but does not require client certificates. This option is necessary if you want to enable mTLS for applications and TLS is terminated for the first time at HAProxy

- **HAProxy does not request client certificates.** This option requires mutual authentication, which makes it incompatible with XFCC option **TLS terminated for the first time at HAProxy**. HAProxy does not request client certificates, so the client does not provide them and no validation occurs. This is the default configuration.
- **HAProxy requests but does not require client certificates.** The HAProxy requests client certificates in TLS handshakes, validates them when presented, but does not require them.

 **warning:** Upon upgrade, PAS will fail to receive requests if your load balancer is configured to present a client certificate in the TLS handshake with HAProxy but HAProxy has not been configured with the certificate authority used to sign it. To mitigate this issue, select **HAProxy does not request client certificates** in the **Networking** pane or configure the HAProxy with the appropriate CA.

10. To configure Gorouter behavior for handling client certificates, select one of the following options in the **Router behavior for Client Certificate Validation** field.

Router behavior for Client Certificate Validation*

☐ Router does not request client certificates. This option is incompatible with XFCC options "TLS terminated for the first time at HAProxy" and "TLS terminated for the first time at the Router" because these options require mutual authentication.

☒ Router requests but does not require client certificates.

☐ Router requires client certificates.

- **Router does not request client certificates.** This option is incompatible with the XFCC configuration options **TLS terminated for the first time at HAProxy** and **TLS terminated for the first time at the Router** in PAS because these options require mutual authentication. As client certificates are not requested, client will not provide them, and thus validation of client certificates will not occur.
- **Router requests but does not require client certificates.** The Gorouter requests client certificates in TLS handshakes, validates them when presented, but does not require them. This is the default configuration.
- **Router requires client certificates.** The Gorouter validates that the client certificate is signed by a Certificate Authority that the Gorouter trusts. If the Gorouter cannot validate the client certificate, the TLS handshake fails.

⚠ warning: Requests to the platform will fail upon upgrade if your load balancer is configured with client certificates and the Gorouter does not have the certificate authority. To mitigate this issue, select **Router does not request client certificates** for **Router behavior for Client Certificate Validation** in the **Networking** pane.

11. In the **TLS Cipher Suites for Router** field, review the TLS cipher suites for TLS handshakes between Gorouter and front-end clients such as load balancers or HAProxy. The default value for this field is `ECDHE-RSA-AES128-GCM-SHA256:TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384`. If you want to modify the default configuration, use an ordered, colon-delimited list of Golang-supported TLS cipher suites in the OpenSSL format. Operators should verify that the ciphers are supported by any clients or front-end components that will initiate TLS handshakes with Gorouter. For a list of TLS ciphers supported by Gorouter, see [Securing Traffic into Cloud Foundry](#).

TLS Cipher Suites for Router *

ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384

Verify that every client participating in TLS handshakes with Gorouter has at least one cipher suite in common with Gorouter.

💡 Note: Specify cipher suites that are supported by the versions configured in the **Minimum version of TLS supported by HAProxy and Router** field.

12. In the **TLS Cipher Suites for HAProxy** field, review the TLS cipher suites for TLS handshakes between HAProxy and its clients such as load balancers and Gorouter. The default value for this field is the following: `DHE-RSA-AES128-GCM-SHA256:DHE-RSA-AES256-GCM-SHA384:ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384`. If you want to modify the default configuration, use an ordered, colon-delimited list of TLS cipher suites in the OpenSSL format. Operators should verify that the ciphers are supported by any clients or front-end components that will initiate TLS handshakes with HAProxy.

TLS Cipher Suites for HAProxy *

DHE-RSA-AES128-GCM-SHA256:DHE-RSA-AES256-GCM-SHA384:ECDHE-RSA-AES128-GCM-SHA256:ECDHE-RSA-AES256-GCM-SHA384

Verify that every client participating in TLS handshakes with HAProxy has at least one cipher suite in common with HAProxy.

💡 Note: Specify cipher suites that are supported by the versions configured in the **Minimum version of TLS supported by HAProxy and Router** field.

13. Under **HAProxy forwards requests to Router over TLS**, select **Enable** or **Disable** based on your deployment layout.

HAProxy forwards requests to Router over TLS. When enabled, HAProxy will forward all requests to the Router over TLS. HAProxy will use the CA provided to verify the certificates provided by the Router. *

☒ Enable

Certificate Authority for HAProxy Backend *

You need to provide a certificate authority for the certificate and key provided in the "Certificate and Private Key for HAProxy and Router" field. HAProxy will verify those certificates using this CA when establishing a connection. If you generated that certificate and key using the "Generate RSA Certificate" feature, then your CA is the Ops Manager CA, and can be found by visiting the "/api/v0/certificate_authorities" API endpoint.

☐ Disable

◦ Enable HAProxy forwarding of requests to Router over TLS

| If you want to: | Encrypt communication between HAProxy and the Gorouter |
|-------------------------------|---|
| Then configure the following: | <ol style="list-style-type: none"> 1. Leave Enable selected. 2. In the Certificate Authority for HAProxy Backend field, specify the Certificate Authority (CA) that signed the certificate you configured in the Certificate and Private Key for HAProxy and Router field. <div>  Note: If you used the Generate RSA Certificate link to generate a self-signed certificate, then the CA to specify is the Ops Manager CA, which you can locate at the <code>/api/v0/certificate_authorities</code> endpoint in the Ops Manager API. </div> <ol style="list-style-type: none"> 3. Make sure that Gorouter and HAProxy have TLS cipher suites in common in the TLS Cipher Suites for Router and TLS Cipher Suites for HAProxy fields. |
| See also: | <ul style="list-style-type: none"> ◦ Terminating SSL/TLS at the Load Balancer and Gorouter ◦ Providing a Certificate for Your SSL/TLS Termination Point ◦ Using the Ops Manager API |

◦ Disable HAProxy forwarding of requests to Router over TLS

| If you want to: | Use non-encrypted communication between HAProxy and Gorouter, or you are not using HAProxy |
|-------------------------------|---|
| Then configure the following: | <ol style="list-style-type: none"> 1. Select Disable. 2. If you are not using HAProxy, set the number of HAProxy job instances to <code>0</code> on the Resource Config page. See Disable Unused Resources. |
| See also: | <ul style="list-style-type: none"> ◦ Terminating SSL/TLS at the Gorouter Only ◦ Terminating SSL/TLS at the Load Balancer Only |

14. If you are not using SSL encryption or if you are using self-signed certificates, select **Disable SSL certificate verification for this environment**. Selecting this checkbox also disables SSL verification for route services.

 **Note:** For production deployments, Pivotal does not recommend disabling SSL certificate verification.

15. (Optional) If you want HAProxy or the Gorouter to reject any HTTP (non-encrypted) traffic, select the **Disable HTTP on HAProxy and Gorouter** checkbox. When selected, HAProxy and Gorouter will not listen on port 80.

☐ Disable HTTP on HAProxy and Gorouter

16. (Optional) Select the **Disable insecure cookies on the Router** checkbox to set the secure flag for cookies generated by the router.
17. (Optional) To disable the addition of Zipkin tracing headers on the Gorouter, deselect the **Enable Zipkin tracing headers on the router** checkbox. Zipkin tracing headers are enabled by default. For more information about using Zipkin trace logging headers, see [Zipkin Tracing in HTTP Headers](#).
18. (Optional) To stop the Router from writing access logs to local disk, deselect the **Enable Router to write access logs locally** checkbox. You should consider disabling this checkbox for high traffic deployments since logs may not be rotated fast enough and can fill up the disk.
19. (Optional) By default, Gorouter support for the PROXY protocol is disabled. To enable the PROXY protocol, select **Enable support for PROXY protocol in CF Router**. When enabled, client-side load balancers that terminate TLS but do not support HTTP can pass along information from the originating client. Enabling this option may impact Gorouter performance. For more information about enabling the PROXY protocol in Gorouter, see the *HTTP Header Forwarding* sections in the [Securing Traffic in Cloud Foundry](#) topic.
20. **Bypass security checks for route service lookup** has potential security concerns, but may be needed for backwards compatibility. See the *Route Service Internal Lookup Considerations* section of [Route Services](#) for details.
21. (Optional) If you want to limit the number of app connections to the backend, enter a value in the **Max Connections Per Backend** field. You can use this field to prevent a poorly behaving app from all the connections and impacting other apps.

To choose a value for this field, review the peak concurrent connections received by instances of the most popular apps in your deployment. You can determine the number of concurrent connections for an app from the `httpStartStop` event metrics emitted for each app request.

If your deployment uses PCF Metrics, you can also obtain this peak concurrent connection information from [Network Metrics](#). The default value is

Max Connections Per Backend *

500

22. Under **Enable Keepalive Connections for Router**, select **Enable** or **Disable**. Keepalive connections are enabled by default. For more information, see [Keepalive Connections](#) in *HTTP Routing*.

Enable Keepalive Connections for Router *

☒ Enable

☐ Disable

23. (Optional) To accommodate larger uploads over connections with high latency, increase the number of seconds in the **Router Timeout to Backends** field.
24. (Optional) Increase the value of **Load Balancer Unhealthy Threshold** to specify the amount of time, in seconds, that the router continues to accept connections before shutting down. During this period, healthchecks may report the router as unhealthy, which causes load balancers to failover to other routers. Set this value to an amount greater than or equal to the maximum time it takes your load balancer to consider a router instance unhealthy, given contiguous failed healthchecks.
25. (Optional) Modify the value of **Load Balancer Healthy Threshold**. This field specifies the amount of time, in seconds, to wait until declaring the Router instance started. This allows an external load balancer time to register the Router instance as healthy.

Load Balancer Unhealthy Threshold *

Load Balancer Healthy Threshold *

26. (Optional) If app developers in your organization want certain HTTP headers to appear in their app logs with information from the Gorouter, specify them in the **HTTP Headers to Log** field. For example, to support app developers that deploy Spring apps to PCF, you can enter [Spring-specific HTTP headers](#).

HTTP Headers to Log

27. If you expect requests larger than the default maximum of 16 Kbytes, enter a new value (in bytes) for **HAProxy Request Max Buffer Size**. You may need to do this, for example, to support apps that embed a large cookie or query string values in headers.

28. If your PCF deployment uses HAProxy and you want it to receive traffic only from specific sources, use the following fields:

- **HAProxy Protected Domains:** Enter a comma-separated list of domains to protect from unknown source requests.
- **HAProxy Trusted CIDRs:** Optionally, enter a space-separated list of CIDRs to limit which IP addresses from the **Protected Domains** can send traffic to PCF.

HAProxy Protected Domains

A comma-separated list of domains to protect from requests from unknown sources. Use this property in conjunction with "Trusted CIDRs" to protect these domains from requests from unknown sources.

HAProxy Trusted CIDRs

29. For **DNS Search Domains**, enter DNS search domains as a comma-separated list. Your containers append these search domains to hostnames to resolve them into full domain names.

DNS Search Domains

example.com, myapps.com

DNS search domains to be used in containers. A comma-separated list can be specified.

30. Select a sharding mode in the **Router Sharding Mode** field. The options are explained below. For more information, see [Sharding Routers for Isolation Segments](#).

Router Sharding Mode: When 'Isolation Segment Only' is selected, the routers of this tile will only have knowledge of applications deployed to the Cells of this tile; all other requests will receive a 404 response. When 'No Isolation Segments' is selected, the routers of this tile will reject requests for any isolation segment. Choose 'No Isolation Segments' to add a group of routers for the Elastic Runtime tile, as when a private point of entry for the system domain is desired.*

- ☒ Isolation Segment Only
- ☐ No Isolation Segment

Save

| Option Name | Description |
|------------------------|--|
| Isolation Segment Only | The routers for the tile acknowledge requests only from apps deployed within the cells of the tile. All other requests fail. |
| No Isolation Segment | The routers for the tile reject requests for any isolation segment. Choose this option to add a group of routers for the PAS tile, such as when you want a private point of entry for the system domain. |

31. Click **Save**.

Application Containers Perform the following steps to configure the PCF Isolation Segment tile: 1. Click ****Application Containers****.

Enable custom configuration that supports your applications at a container level.

Private Docker Insecure Registry Whitelist

10.10.10.10:8888,example.com:8888

Segment Name *

DNS Servers

Docker Images Disk-Cleanup Scheduling on Cell VMs *

☐ Never clean up Cell disk-space

☐ Routinely clean up Cell disk-space

☒ Clean up disk-space once threshold is reached

Threshold of Disk-Used (MB) (min: 1) *

10240

Disk cleanup will initiate whenever a Cell has exceeded this much disk-space for filesystem layers.

1. (Optional): Under **Private Docker Insecure Registry Whitelist**, enter one or more private Docker image registries that are secured with self-signed certificates. Use a comma-delimited list in the format ``IP:Port`` or ``Hostname:Port``. 1. Under **Segment Name**, enter the name of your isolation segment. This name must be unique across your PCF deployment. You use this name when performing the steps in the [Create an Isolation Segment](../adminguide/isolation-segments.html#create-an-is) section of the *Managing Isolation Segments* topic to create the isolation segment in the Cloud Controller Database (CCDB). 1. Select your preference for **Docker Images Disk-Cleanup Scheduling on Cell VMs**. If you choose **Clean up disk-space once threshold is reached**, enter a **Threshold of Disk-Used** in megabytes. For more information about the configuration options and how to configure a threshold, see [Configuring Docker Images Disk-Cleanup Scheduling](../opsguide/config-cell-cleanup.html). 1. Under **Enabling NFSv3 volume services**, select **Enable** or **Disable**. NFS volume services allow application developers to bind existing NFS volumes to their applications for shared file access. For more information, see the [Enabling NFS Volume Services](../opsguide/enable-vol-services.html) topic.

Note: In a clean install, NFSv3 volume services are enabled by default. In an upgrade, NFSv3 volume services match the setting of the previous deployment.

1. (Optional) To configure LDAP for NFSv3 volume services, perform the following steps:

- For **LDAP Service Account User**, enter the username of the service account in LDAP that will manage volume services.
- For **LDAP Service Account Password**, enter the password for the service account.
- For **LDAP Server Host**, enter the hostname or IP address of the LDAP server.
- For **LDAP Server Port**, enter the LDAP server port number. If you do not specify a port number, Ops Manager uses port 389.
- For **LDAP User Fully-Qualified Domain Name**, enter the fully qualified path to the LDAP service account. For example, if you have a service account called `volume-services` that belongs to organizational units (OU) called `service-accounts` and `my-company`, and your domain is called `domain`, the fully qualified path looks like the following:

CN=volume-services,OU=service-accounts,OU=my-company,DC=domain,DC=com

2. By default, PAS manages container images using the [GrootFS](#) plugin for Garden-runC. If you experience issues with GrootFS, you can disable the plugin and use the image plugin built into Garden-runC.

Note: If you modify this setting, Pivotal recommends recreating all VMs in the BOSH Director config. You can do this by selecting the **Recreate all VMs** checkbox in the **Director Config** pane of the BOSH Director tile before you redeploy.

3. To enable Gorouter to verify app identity using TLS, select the **Router uses TLS to verify application identity** checkbox. Verifying app identity using TLS improves resiliency and consistency for app routes. For more information about Gorouter route consistency modes, see [Preventing Misrouting in HTTP Routing](#).
4. Click **Save**.

System Logging

1. In the **System Logging** menu, select an option underneath **Do you want to configure syslog for system components?**. **No** is selected by default. This setting only affects Diego cell, router, and HAProxy components within the isolation segment, not shared PAS system components.

Configure system logging. Complete the External Syslog fields only if using an external syslogd server.

Do you want to configure syslog for system components?*

☒ No

☐ Yes

[Save](#)

2. If you want to use syslog, select **Yes**.

Do you want to configure syslog for system components? *

☐ No

☒ Yes

Address *

Port *

Transport Protocol *

TCP protocol

☐ Enable TLS

Permitted Peer

TLS CA Certificate

☒ Use TCP for file forwarding local transport

Workaround to avoid truncation of very long (> 1024 bytes) log lines. May negatively impact performance.

☒ Don't Forward Debug Logs

Custom rsyslog Configuration

Save

3. Enter the address of your external syslog aggregation service in the **Address** field. The address can be a hostname or IP address.
4. Enter a port number in the **Port** field.
5. Select a protocol from the **Transport Protocol** menu. This is the protocol the system uses to transmit logs to syslog.
6. (Optional) Select the **Enable TLS** option if you want to transmit logs over TLS.
7. Enter a **Permitted Peer**.
8. Paste the certificate for your TLS certificate authority (CA) in the **TLS CA Certificate** field.
9. (Optional) Select the **Use TCP for file forwarding local transport** to transmit logs over TCP, rather than UDP. This prevents log truncation, but may cause performance issues.
10. (Optional) To forward DEBUG syslog messages to an external service, disable the **Don't Forward Debug Logs** checkbox. This checkbox is enabled in PCF Isolation Segment by default.

 **Note:** Some PCF Isolation Segment components generate a high volume of DEBUG syslog messages. Using the **Don't Forward Debug Logs**

checkbox prevents them from being forwarded to external services. PCF Isolation Segment still writes the messages to the local disk.

11. (Optional) To specify a custom syslog rule, enter it in the **Custom rsyslog Configuration** field in [RainerScript](#) [↗](#) syntax. For more information about customizing syslog rules, see [Customizing Syslog Rules](#).
12. Click **Save**.

Advanced Features

The **Advanced Features** section of Pivotal Application Service (PAS) includes new functionality that may have certain constraints. Although these features are fully supported, Pivotal recommends caution when using them in production environments.

Diego Cell Memory and Disk Overcommit

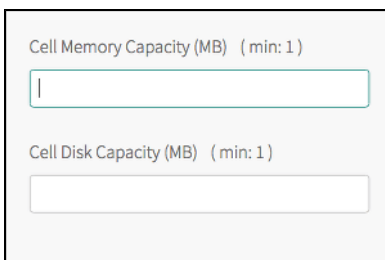

If your apps do not use the full allocation of disk space and memory set in the **Resource Config** tab, you might want use this feature. These fields control the amount to overcommit disk and memory resources to each Diego Cell VM.

For example, you might want to use the overcommit if your apps use a small amount of disk and memory capacity compared to the amounts set in the **Resource Config** settings for **Diego Cell**.

 **Note:** Due to the risk of app failure and the deployment-specific nature of disk and memory use, Pivotal has no recommendation about how much, if any, memory or disk space to overcommit.

To enable overcommit, do the following:

1. Select **Advanced Features**.

The screenshot shows a configuration form with two input fields. The first field is labeled 'Cell Memory Capacity (MB) (min: 1)' and the second field is labeled 'Cell Disk Capacity (MB) (min: 1)'. Both fields are empty and have a light blue border.

2. Enter the total desired amount of Diego cell memory value in the **Cell Memory Capacity (MB)** field. Refer to the **Diego Cell** row in the **Resource Config** tab for the current Cell memory capacity settings that this field overrides.
3. Enter the total desired amount of Diego cell disk capacity value in the **Cell Disk Capacity (MB)** field. Refer to the **Diego Cell** row in the **Resource Config** tab for the current Cell disk capacity settings that this field overrides.
4. Click **Save**.

 **Note:** Entries made to each of these two fields set the total amount of resources allocated, not the overage.

Configure Router Resources

1. Select **Resource Config**.

Resource Config

| JOB | INSTANCES | PERSISTENT DISK TYPE | VM TYPE | LOAD BALANCERS | INTERNET CONNECTED |
|------------|--------------|----------------------|---|----------------|-------------------------------------|
| Router | Automatic: 3 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |
| Diego Cell | Automatic: 3 | None | Automatic: xlarge.disk (cpu: 4, ram: 16 GB, disk: 128 GB) | | <input checked="" type="checkbox"/> |
| HAProxy | Automatic: 3 | None | Automatic: micro (cpu: 1, ram: 1 GB, disk: 8 GB) | | <input checked="" type="checkbox"/> |

Save

- If you are using a dedicated router for your isolation segment, follow the instructions below.

 **Note:** The configuration settings available in **Resource Config** vary depending on your IaaS.

- If you have the Load Balancers column in your Resource Config:
 - Enter the wildcard DNS entry attached to your load balancer into the **Router** row under **Load Balancers**.
- If you do not have the Load Balancers column in your Resource Config:
 - Navigate to the **Networking** section of the **PCF Isolation Segment** tile.
 - Specify **Router IPs**.
 - Attach the IP addresses to your load balancer manually.

- If you are not using HAProxy for this isolation segment, set the number of **Instances** to .

After Tile Configuration

After you configure the PCF Isolation Segment tile, perform the following steps:

- Create the isolation segment in the Cloud Controller Database (CCDB) by following the procedure in the [Create an Isolation Segment](#) section of the *Managing Isolation Segments* topic.
- Return to the Ops Manager Installation Dashboard and click **Apply Changes** to deploy the tile.

After the tile finishes deploying, see the [Managing Isolation Segments](#) topic for more information about managing an isolation segment.

Step 4: (Optional) Copy the Tile

If you want to create multiple isolation segments, perform the following steps to copy the PCF Isolation Segment tile with the Replicator tool:

- Download the Replicator tool from the **Pivotal Cloud Foundry Isolation Segment** section of [Pivotal Network](#).
- Navigate to the directory where you downloaded the Replicator tool.
- Replicate the tile:

```
./replicator \
--name "YOUR-NAME" \
--path /PATH/TO/ORIGINAL.pivotal \
--output /PATH/TO/COPY.pivotal
```

Replace the values above with the following:

- YOUR-NAME**: Provide a unique name for the new PCF Isolation Segment tile. The name must be ten characters or less and only contain alphanumeric characters, dashes, underscores, and spaces.
- /PATH/TO/ORIGINAL**: Provide the absolute path to the original PCF Isolation Segment tile you downloaded from Pivotal Network.
- /PATH/TO/COPY**: Provide the absolute path for the copy that the Replicator tool produces.

- Follow the procedures in this topic using the new `.pivotal` file, starting with [Step 1](#).

Upgrading Replicated Tiles

For information about upgrading replicated Isolation Segment tiles, see [Upgrading Replicated Tiles](#).

Getting Started with Small Footprint PAS

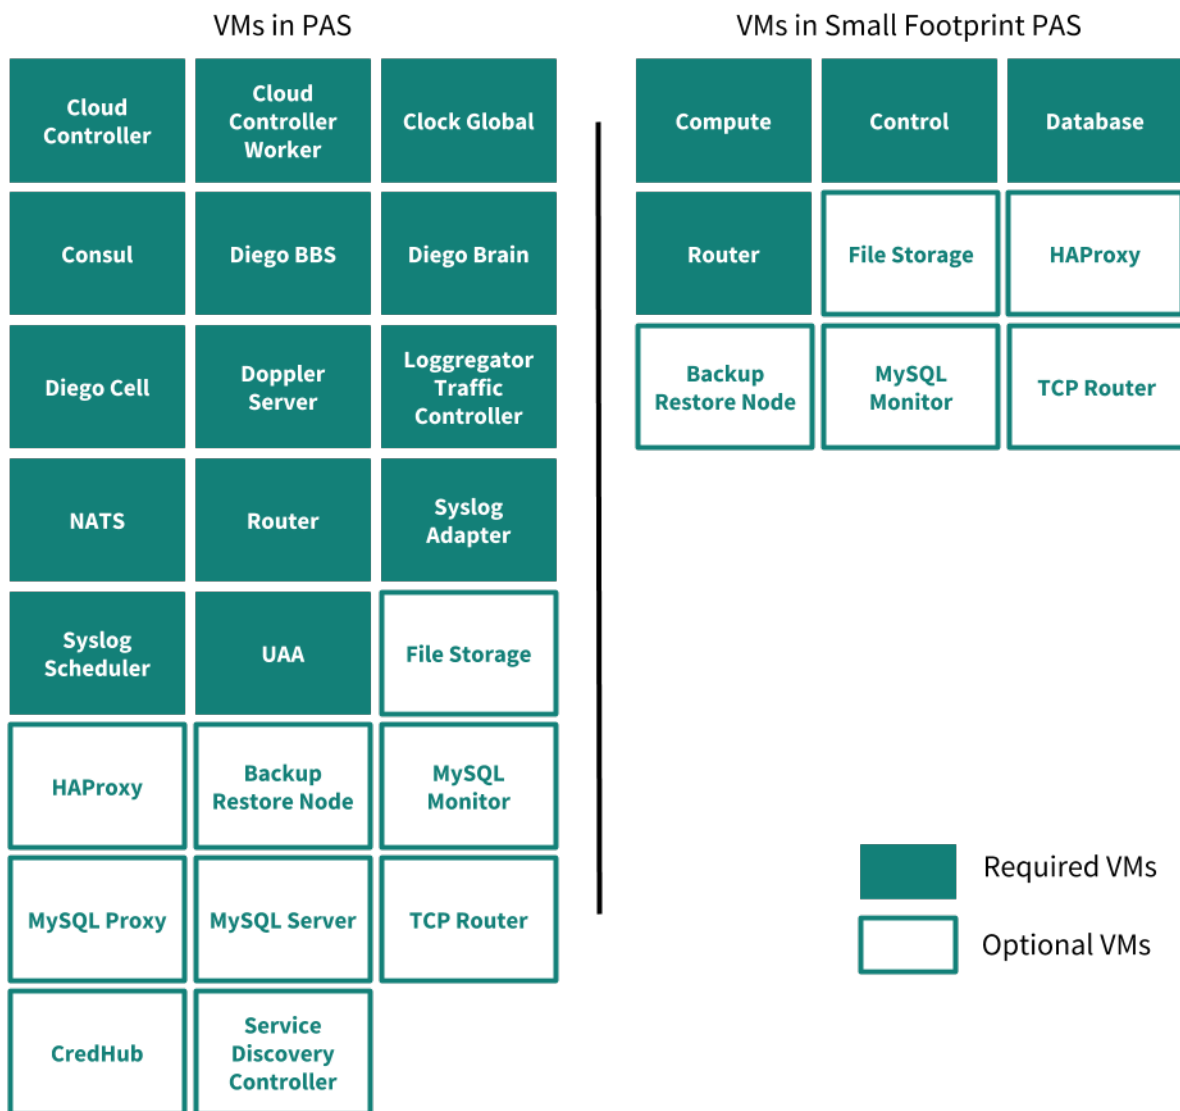

This topic describes the Small Footprint Pivotal Application Services (PAS) tile for Pivotal Cloud Foundry (PCF).

The Small Footprint PAS is a repackaging of the PAS components into a smaller deployment with fewer virtual machines (VMs). The [Limitations](#) section describes the limitations that come with a smaller deployment.

Differentiate Small Footprint PAS and PAS

A standard PAS deployment must have at least 14 VMs, but the Small Footprint PAS requires only four.

The following image displays a comparison of the number of VMs deployed by PAS and Small Footprint PAS.

Use Cases

Use the Small Footprint PAS tile for smaller PCF deployments on which you intend to host 2500 or fewer apps, as described in the [Limitations](#) section. If you want to use Small Footprint PAS in a production environment, ensure the *Limitations* described below are not an issue in your use case.

Note: The Small Footprint PAS is compatible with PCF service tiles.

The Small Footprint PAS tile is also ideal for the following use cases:

- **Proof-of-concept installations:**
 - Deploy PCF quickly and with a small footprint for evaluation or testing purposes.
- **Sandbox installations:**
 - Use Small Footprint PAS as a PCF operator sandbox for tasks such as testing compatibility.
- **Service tile R&D:**
 - Test a service tile against Small Footprint PAS instead of a standard PAS deployment to increase efficiency and reduce cost.

Limitations

The Small Footprint PAS has the following limitations:

- **Number of app instances:**
 - The tile is not designed to support large numbers of app instances. You cannot scale the number of [Compute VMs](#) beyond instances in the **Resource Config** pane. The Small Footprint PAS is designed to support 2500 or fewer apps.
- **Increasing platform capacity:**
 - You cannot upgrade the Small Footprint PAS to the standard PAS tile. If you expect platform usage to increase beyond the capacity of the Small Footprint PAS, Pivotal recommends using the standard PAS tile.
- **Management plane availability during tile upgrades:**
 - You may not be able to perform management plane operations like deploying new apps and accessing APIs for brief periods during tile upgrades. The management plane is colocated on the [Control VM](#).
- **App availability during tile upgrades:**
 - If you require availability during your upgrades, you must scale your **Compute VMs** to a highly available configuration. Ensure sufficient capacity exists to move app instances between Compute VM instances during the upgrade.

Architecture

You can deploy the Small Footprint PAS tile with a minimum of four VMs, as shown in the image below.

 **Note:** The following image assumes that you are using an external blobstore.

VMs in Small Footprint PAS

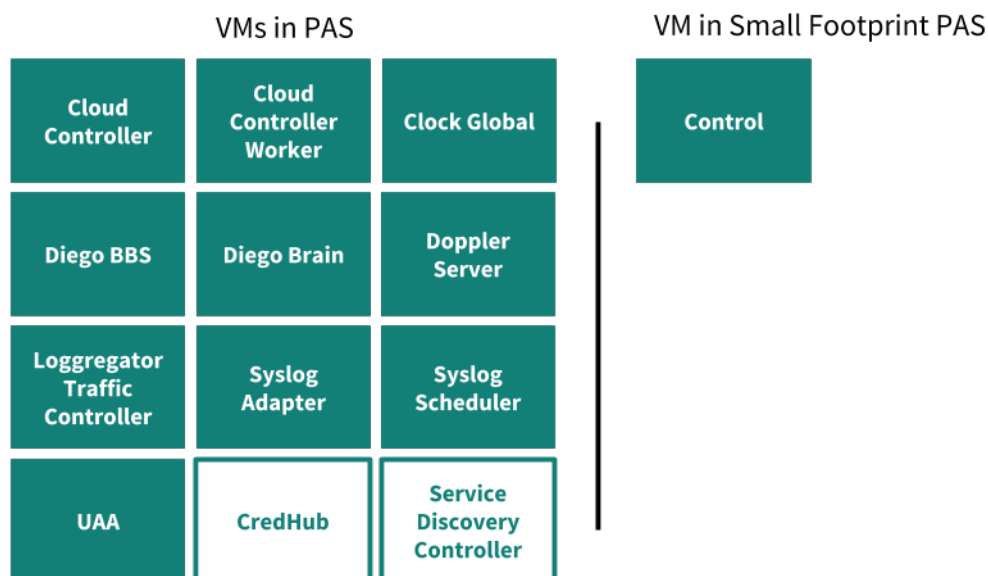

To reduce the number of VMs required for Small Footprint PAS, the *Control* and *Database* VMs include colocated jobs that run on a single VM in PAS. See the next sections for details.

For more information about the components mentioned on this page, see the *Architecture* section of the [Cloud Foundry Concepts](#) guide.

Control VM

The Control VM includes the PAS jobs that handle management plane operations, app lifecycles, logging, and user authorization and authentication. Additionally, all errands run on the Control VM, eliminating the need for a VM for each errand and significantly reducing the time it takes to run errands.

The following image shows all the jobs from PAS that are colocated on the Control VM in Small Footprint PAS.

Database VM

The database VM includes the PAS jobs that handle internal storage and messaging.

The following image shows all the jobs from PAS that are colocated on the Database VM in Small Footprint PAS.

Compute VM

The *Compute* VM is the same as the Diego Cell VM in PAS.

Other VMs (Unchanged)

The following image shows the VMs performs the same functions in both versions of the PAS tile.

Requirements

The following topics list the minimum resources needed to run Small Footprint PAS and Ops Manager on the public IaaSes that PCF supports:

- [Installing PCF on AWS](#)
- [Installing PCF on Azure](#)
- [Installing PCF on GCP](#)
- [Installing PCF on vSphere](#)

Installing Small Footprint PAS

To install the Small Footprint PAS tile, follow the instructions for [Installing Pivotal Cloud Foundry](#) on your IaaS.

Follow the same installation and configuration steps as for PAS, with the following differences:

- **Selecting a product in Pivotal Network:**
 - When you navigate to the PAS tile on [Pivotal Network](#), select the **Small Footprint** release.
- **Configuring resources:**
 - The **Resource Config** pane in the Small Footprint PAS tile reflects the differences in VMs discussed in the *Architecture* section of this topic.
 - Small Footprint PAS does not default to a highly available configuration like PAS does. It defaults to a minimum configuration. To make Small Footprint PAS highly available, scale the VMs to the following instance counts:
 - **Compute:** 3
 - **Control:** 2
 - **Database:** 3
 - **Router:** 3
- **Configuring load balancers:**
 - If you are using an SSH load balancer, you must enter its name in the **Control VM** row of the **Resource Config** pane. There is no **Diego Brain** row in Small Footprint Runtime because the Diego Brain is colocated on the Control VM. You can still enter the appropriate load balancers in the **Router** and **TCP Router** rows as normal.

Troubleshooting Colocated Jobs Using Logs

If you need to troubleshoot a job that runs on the Control or Database VMs, do the following:

- Follow the procedures in *Advanced Troubleshooting with the BOSH CLI* to the log in to the BOSH Director for your deployment:
 - [Gather Credential and IP Address Information](#)
 - [SSH into Ops Manager](#)
 - [Log in to the BOSH Director](#)
- Use BOSH to list the VMs in your Small Footprint PAS deployment:

```
bosh -e MY-ENV -d MY-DEPLOYMENT vms
```

 **Note:** If you do not know the name of your deployment, you can run `bosh -e MY-ENV deployments` to list the deployments for your BOSH Director.

See the following example output:

```
$ bosh -e example-env -d example-deployment vms
Using environment 'example-env' as client 'ops_manager'
```

Task 182. Done

Deployment 'example-deployment'

| Instance | Process | State | AZ | IPs | VM CID | VM Type |
|---|---------|---------|----|-----|-------------------------|---|
| backup-prepare/8fd07242-cf7c-4a4d-ba69-85fe078114f9 | | running | | | us-central1-a 10.0.4.10 | vm-6ec72a47-55b0-4767-78af-759f1f295183 micro |

13 vms

Succeeded

- Use BOSH to SSH into one of the Small Footprint PAS VMs.

```
bosh -e MY-ENV -d MY-DEPLOYMENT ssh VM-NAME/GUID
```

For example, to SSH into the Control VM, run the following:

```
$ bosh -e example-env -d example-deployment ssh control/12b1b027-7ffd-43ca-9dc9-7f4ff204d86a
```

- Run `sudo su` to act as super user.
- Use `monit` to list the processes running on the VM.

```
monit summary
```

See the following example output that lists the processes running on the Control VM. The processes listed reflect the colocation of jobs as outlined in the *Architecture* section of this topic.

```
control/12b1b027-7ffd-43ca-9dc9-7f4ff204d86a:/var/vcap/bosh_ssh/bosh_f9d2446b18b445e# monit summary
The Monit daemon 5.2.5 uptime: 5d 21h 10m
```

```
Process 'consul_agent'      running
Process 'bbs'              running
Process 'metron_agent'     running
Process 'locket'           running
Process 'route_registrar'  running
Process 'policy-server'    running
Process 'silk-controller'  running
Process 'uaa'              running
Process 'statsd_injector'  running
Process 'cloud_controller_ng' running
Process 'cloud_controller_worker_local_1' running
Process 'cloud_controller_worker_local_2' running
Process 'nginx_cc'         running
Process 'routing-api'      running
Process 'cloud_controller_clock' running
Process 'cloud_controller_worker_1' running
Process 'auctioneer'       running
Process 'cc_uploader'       running
Process 'file_server'       running
Process 'nsync_listener'   running
Process 'ssh_proxy'        running
Process 'tps_watcher'      running
Process 'stager'           running
Process 'loggregator_trafficcontroller' running
Process 'reverse_log_proxy' running
Process 'adapter'          running
Process 'doppler'          running
Process 'syslog_drain_binder' running
System 'system_localhost'  running
```

6. To access logs, navigate to `/vars/vcap/sys/log` :

```
cd /var/vcap/sys/log
```

7. Run `ls` to list the log directories for each process. See the following example output from the Control VM:

```
control/12b1b027-7ffd-43ca-9dc9-7f4ff204d86a:/var/vcap/sys/log# ls
adapter  cloud_controller_clock  file_server  nginx_cc  route_registrar  statsd_injector  uaa_ctl.err.log
auctioneer  cloud_controller_ng  locket      nginx_newrelic_plugin  routing-api  syslog_drain_binder  uaa_ctl.log
bbs        cloud_controller_worker  loggregator_trafficcontroller  nsync      silk-controller  syslog_forwarder
cc_uploader  consul_agent  metron_agent  policy-server  ssh_proxy  tps
cfdot      doppler      monit        reverse_log_proxy  stager      uaa
```

8. Navigate to the directory of the process that you want to view logs for. For example, for the Cloud Controller process, run `cd cloud_controller_ng/`. From the directory of the process, you can list and view its logs. See the following example output:

```
control/12b1b027-7ffd-43ca-9dc9-7f4ff204d86a:/var/vcap/sys/log/cloud_controller_ng# ls
cloud_controller_ng_ctl.err.log  cloud_controller_ng.log.2.gz  cloud_controller_ng.log.6.gz  drain  pre-start.stdout.log
cloud_controller_ng_ctl.log     cloud_controller_ng.log.3.gz  cloud_controller_ng.log.7.gz  post-start.stderr.log
cloud_controller_ng.log         cloud_controller_ng.log.4.gz  cloud_controller_worker_ctl.err.log  post-start.stdout.log
cloud_controller_ng.log.1.gz    cloud_controller_ng.log.5.gz  cloud_controller_worker_ctl.log  pre-start.stderr.log
```

Release Notes

The Small Footprint PAS tile releases alongside the PAS tile. For more information, see the [PAS Release Notes](#).

Upgrading Pivotal Cloud Foundry

Page last updated:

This topic describes upgrading Pivotal Cloud Foundry (PCF) to v2.2. The upgrade procedure below describes upgrading Pivotal Cloud Foundry Operations Manager (Ops Manager), Pivotal Application Service (PAS), and product tiles.

 **Breaking Changes:** Read the [Release Notes](#) and [Breaking Changes](#) for this release, including the Known Issues sections, before starting the upgrade process.

 **Warning:** Pivotal does not recommend that you skip minor versions when upgrading PCF. Skipping minor versions when upgrading PCF may result in breaking changes. To avoid additional breaking changes, upgrade PCF to the minor version that directly follows your current version of PCF.

The apps in your deployment continue to run during the upgrade. However, you cannot write to your deployment or make changes to apps during the upgrade.

For details about how upgrading PCF impacts individual PAS components, see [Understanding PAS Upgrades](#).

Prepare to Upgrade

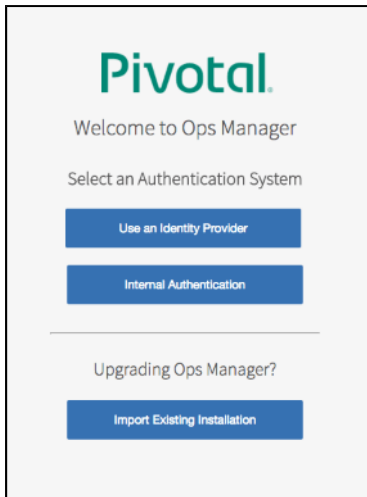

If you have not already, complete the steps in the [Upgrade Preparation Checklist for PCF v2.2](#).

Upgrade Ops Manager and Installed Products to v2.2

Follow these steps to upgrade Ops Manager and Installed Products to PCF v2.2.

Import Installation to Ops Manager v2.2 VM

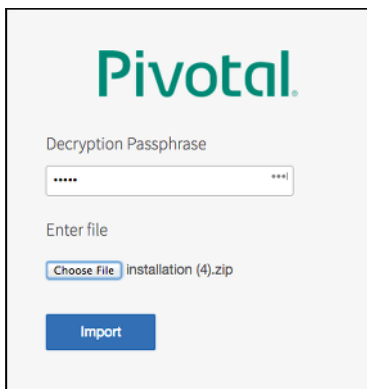

1. Download the Ops Manager VM Template v2.2 from the [Pivotal Network](#)  site.
2. Record the FQDN address of the existing Ops Manager VM.
3. To avoid conflicts, power off the existing Ops Manager VM.
4. Deploy the new Ops Manager VM by following the steps in one of these topics:
 - **AWS:** [Upgrading BOSH Director on AWS](#)
 - **Azure:** [Upgrading BOSH Director on Azure](#)
 - **GCP:** [Upgrading BOSH Director on GCP](#)
 - **OpenStack:** [Deploying Ops Manager to OpenStack](#)
 - **vSphere:** [Deploying Ops Manager on vSphere](#)
5. When redirected to the **Welcome to Ops Manager** page, select **Import Existing Installation**.

- When prompted, enter the **Decryption Passphrase** for this Ops Manager installation. You set this passphrase during your initial installation of Ops Manager.

Note: If lost, the **Decryption Passphrase** cannot be recovered.

- Click **Choose File** and browse to the installation ZIP file exported in the [Export Your Installation](#) step of your upgrade preparation.

- Click **Import**.

Note: Some browsers do not provide feedback on the status of the import process, and might appear to hang.

- A “Successfully imported installation” message appears upon completion.

Import New PAS and Product Tiles

After upgrading to Ops Manager v2.2, upgrade your product versions:

- Import the product file to your Ops Manager **Installation Dashboard**.
- Hover over the product name in **Available Products** and click **Add**.
- Click the newly added tile to review any configurable options.
- (Optional) If you use other service tiles, you can upgrade them following the same procedure. See the [Upgrading PAS and Other Pivotal Cloud](#)

[Foundry Products](#) topic for more information.

Perform Your Upgrade

⚠ warning: If the installation fails or returns errors, contact [Support](#). Do not attempt to roll back the upgrade by restarting the previous (v2.1) Ops Manager VM.

1. Navigate to the Ops Manager **Installation Dashboard**.
2. Click **Apply Changes**. This immediately imports and applies upgrades to all tiles in a single transaction.

💡 Breaking Change: Only use **Apply Changes** to upgrade tiles immediately after upgrade. Do not use **Review Pending Changes** for selective deployment. For more information, see [Redeploy All Products After Upgrading to Ops Manager v2.2](#)

3. Click each service tile, select the **Status** tab, and confirm that all VMs appear and are in good health.
4. After confirming that the new installation functions correctly, remove the v2.1 Ops Manager VM.

Monitor Upgrade

During the upgrade, you can do the following to monitor your PCF foundation and help troubleshoot any issues.

Check Status and Performance

Note/Reason:

Monitor the progress of the upgrade, checking the status of the foundation at various locations.

Product/component:

PCF

Pivotal recommends live-monitoring your upgrade with PCF Healthwatch, which monitors and alerts on the current health, performance, and capacity of PCF. Healthwatch captures, calculates, stores, visualizes, and alerts on PCF platform metrics, including:

- BOSH-reported VM metrics
- Runtime component metrics
- [Key Performance Indicators](#) and [Key Scaling Indicators](#)
- Healthwatch-generated [super metrics](#)

For more information, see the [PCF Healthwatch documentation](#).

If you are not using PCF Healthwatch, you can do some or all of the following to monitor upgrade progress:

- Run BOSH CLI status checks:

- `bosh -e ALIAS task TASK_NUMBER`
- `bosh -e ALIAS vms --vitals, bosh -e ALIAS instances --ps`

- Check app availability
- Run cf CLI Commands
- Check the availability of the Ops Manager GUI
- Check NAS performance (if using NAS)
- Check vSphere performance (if on vSphere)

Check Diego State

Note/Reason:

See the [cfdot documentation](#) on GitHub for details.

Product/component:

PAS

Use the CF Diego Operator Toolkit (cfdot) to check Diego component instance count by current state.

(Optional) Take Snapshots of Storage Metrics

Note/Reason:

Pivotal recommends this if you have a large foundation and have experienced storage issues in the past.

Product/component:

PCF

Periodically take snapshots of storage metrics.

(Optional) Collect Logs

Note/Reason:

This information helps determine the cause of upgrade issues.

Product/component:

PCF

If you encounter problems during upgrade, collect the following information:

- All job logs
- Task debug logs for VM upgrade tasks
- Installation log from Ops Manager

After Upgrade

After your upgrade, do the following to prepare for use of your new environment, check its health status, and clean up.

Re-Create BOSH Alias

Re-create your alias using BOSH:

```
bosh alias-env ALIAS -e
DIRECTOR_IP
```

- **Note/Reason:** To log into BOSH after upgrading PCF, you need to recreate your alias.
- **Product/Component:** BOSH

Install New cf CLI

Download the version of the Cloud Foundry Command Line Interface (cf CLI) packaged with the [PAS](#) tile on Pivotal Network.

⚠ warning: Due to a regression with x.509 certificates in Go v1.10, Pivotal recommends downloading cf CLI v6.36.2 or later, which use Go v1.9. For more information, see the [v6.36.2](#) change log and [Known Issues](#) in the *Pivotal Application Service v2.2 Release Notes* topic.

Check the Health of Your Deployment

1. Run BOSH CLI commands to check system status:

- ```
bosh -e ALIAS -d DEPLOYMENT_NAME instances --ps
```
- ```
bosh -e ALIAS vms --vitals
```
- ```
bosh -e ALIAS -d DEPLOYMENT_NAME cck --report
```

**Note/Reason:** To ensure that all jobs and process are running as expected

**Product/Component:** PCF and all tiles

2. Push and horizontally scale a test application.

- **Note/Reason:** This is a performance test for PAS.
- **Product/Component:** PCF

3. If you are running PAS MySQL as a cluster, run the `mysql-diag` tool to validate health of the cluster.

- **Note/Reason:** See the BOSH CLI v2 instructions in the [Running mysql-diag](#) [↗](#) topic.
- **Product/Component:** PAS

## Check Resource Settings

If you added custom **VM Type** or **Persistent Disk Type** options, ensure that these values are correctly set and were not overwritten.

- **Note/Reason:** Verify that the Ops Manager **Resource Config** pane still lists your custom options.
- **Product/Component:** PCF

## Run BOSH Clean-Up

Run `bosh -e ALIAS clean-up --all` to clean up old stemcells, releases, orphaned disks, and other unused resources.

- **Product/Component:** Tiles

## What Happens During PAS Upgrades

This topic explains what happens to Pivotal Application Service (PAS) components and apps during a PAS upgrade.

### BOSH Drains Diego Cell VMs

During a PAS upgrade, BOSH drains all Diego cell VMs that host app instances. BOSH manages this process by upgrading a batch of cells one at a time.

When BOSH triggers an upgrade, each upgrading Diego cell enters evacuation mode. In evacuation mode, BOSH stops Diego cells and then schedules replacements for its app instances.

For more information, see the [Specific Guidance for Diego Cells](#) section of the *Configuring PAS for Upgrades* topic.

### cf push Can Become Unavailable

`cf push` is mostly available for the duration of a PAS upgrade. However, `cf push` can become unavailable when a single VM is in use or during BOSH Backup and Restore (BBR).

For more information, see [cf push Availability During Pivotal Application Service Upgrades](#).

## PAS Components Upgrade

This section describes the order in which Ops Manager upgrades components and runs tasks during a full platform upgrade. It also explains how the scale of different Pivotal Application Service (PAS) components affects uptime during upgrades, and which components are scalable.

When performing an upgrade, Ops Manager first upgrades individual components, and then runs one-time tasks.

1. The [Components](#) section describes how Ops Manager upgrades PAS components and explains how individual component upgrades affect broader PAS capabilities.
2. The [One-Time Tasks](#) section lists the tasks that Ops Manager runs after it upgrades the PAS components.

### Components

Ops Manager upgrades PAS components in a fixed order that honors component dependencies and minimizes downtime and other system limitations during the upgrade process.

The type and duration of downtime and other limitations that you can expect during a PAS upgrade reflect the following:

- Component instance scaling. See [How Single-Component Scaling Affects Upgrades](#)
- Component upgrade order. See [Component Upgrade Order and Behavior](#)

#### How Single-Component Scaling Affects Upgrades

In [Pivotal Cloud Foundry](#) (PCF) Ops Manager, the Pivotal Application Service (PAS) tile > **Resource Config** pane shows the components that the BOSH Director installs:

- **Scalable** component fields let you select the instance count from a range of settings or enter a custom value.
- **Unscalable** component fields allow a maximum of one instance.

When a component is scaled at a single instance, it can experience downtime and other limitations while the single VM restarts. This behavior might be acceptable for a test environment. To avoid downtime in a production environment, you should scale any scalable components, such as HAProxy, Router, and Diego cells, to more than one instance.

For more information about how the scale of each component affects upgrade behavior, see the [Component Upgrade Order and Behavior](#) table below.

 **Note:** A full Ops Manager upgrade may take close to two hours, and you will have limited ability to deploy an application during this time.

## Component Upgrade Order and Behavior

The table below lists components in the order that Ops Manager upgrades each. It also lists which components are scalable and explains how component downtime affects PAS app and control availability. The table includes the following columns:

- **Scalable:** Indicates whether the component is scalable above a single instance.

 **Note:** For components marked with a checkmark in this column, we recommend that you change the preconfigured instance value of `1` to a value that best supports your production environment. For more information about scaling a deployment, refer to the [Scaling Cloud Foundry](#) topic.

- **Extended Downtime:** Indicates that if there is only one instance of the component, that component is unavailable for up to five minutes during an Ops Manager upgrade.
- **Downtime Affects...:** Indicates the plane of the PAS platform that component downtime affects, if the component is scaled at single instance:
  - **Apps:** Downtime can affect app availability.
  - **Platform:** Apps remain available during component downtime, but you cannot push, stage, or restart apps, or run other Cloud Foundry command-line interface (cf CLI) commands.
- **Other Limitations and Information:** Provides the following information:
  - Component availability, behavior, and usage during an upgrade
  - Guidance on disabling the component before an upgrade

| Upgrade Order | Component               | Scalable | Extended Downtime | Downtime Affects... |          | Other Limitations and Information                                                                                                                                                                                                                                                              |
|---------------|-------------------------|----------|-------------------|---------------------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               |                         |          |                   | Apps                | Platform |                                                                                                                                                                                                                                                                                                |

## Upgrading Installation Example

For sample performance measurements of an upgrading Cloud Foundry installation, see [Upgrade Load Example: Pivotal Web Services](#).

## Upgrade Preparation Checklist for PCF v2.2

This topic serves as a checklist for preparing to upgrade Pivotal Cloud Foundry (PCF) from v2.1 to v2.2.

This topic contains important preparation steps that you must follow before beginning your upgrade. Failure to follow these instructions may jeopardize your existing deployment data and cause the upgrade to fail.

After completing the steps in this topic, you can continue to [Upgrading Pivotal Cloud Foundry](#).

**Warning:** Pivotal does not recommend that you skip minor versions when upgrading PCF. Skipping minor versions when upgrading PCF may result in breaking changes. To avoid additional breaking changes, upgrade PCF to the minor version that directly follows your current version of PCF.

## Back Up Your PCF Deployment

Pivotal recommends backing up your PCF deployment before upgrading, to restore in the case of failure. To do this, follow the instructions in the [Backing Up Pivotal Cloud Foundry with BBR](#) topic.

## Find Your Decryption Passphrase for Ops Manager

To complete the Ops Manager upgrade, you must have your Ops Manager decryption passphrase. You defined this decryption passphrase during the initial installation of Ops Manager.

## Review Changes in PCF v2.2

Review each of the following links to understand the changes in the new release, such as new features, known issues, and breaking changes.

- **Release Notes**
  - [Ops Manager Release v2.2 Release Notes](#)
  - [PAS v2.2 Release Notes](#)
- **Known Issues**
  - [Ops Manager v2.2 Known Issues](#)
  - [PAS v2.2 Known Issues](#)
  - The following Pivotal Knowledge Base (KB) articles describe known issues for **PCF v2.2**:
    - [How to avoid app downtime while upgrading from PAS v2.1.x to v2.2.7 or Later](#)
    - [App Autoscaler Smoke Test Errand fails to retrieve any metrics from logcache](#)

## Update Tiles and Add-Ons

The following section describes changes you must make to your product tiles and add-ons before upgrading PCF.

### Review Tile Compatibility

Before you upgrade to PCF v2.2, please check whether the service tiles that you currently have deployed on PCF v2.1 are compatible with PCF v2.2.

To check PCF versions supported by a service tile, either from Pivotal or a Pivotal partner:

- Navigate to the tile's download page on [Pivotal Network](#).
- Select the tile version in the **Releases** dropdown.
- See the **Depends On** section under **Release Details**. For more information, refer to the tile's release notes.

If the currently-deployed version of a tile is not compatible with PCF v2.2, you must upgrade the tile to a compatible version before you upgrade PCF. You do not need to upgrade tiles that are compatible with both PCF v2.1 and v2.2.

Some partner service tiles may be incompatible with PCF v2.2. Pivotal works with partners to ensure their tiles are updated to work with the latest versions of PCF. For more information about which partner service release compatibility, review the **Depends On** section of the partners tile download page, the partners services release documentation in [Pivotal Documentation](#), or contact the partner organization that produces the service tile.

The [Product Compatibility Matrix](#) provides an overview of which PCF versions support which versions of the most popular service tiles from Pivotal.

### Environment Details

Pivotal provides the empty table below as a model to print out or adapt for recording and tracking the tile versions that you have deployed in all of your environments.

|                                        |                                                   | Sandbox | Non-Prod | Prod | Other... |
|----------------------------------------|---------------------------------------------------|---------|----------|------|----------|
| Pivotal Cloud Foundry                  | <a href="#">Ops Manager</a>                       |         |          |      |          |
|                                        | <a href="#">Pivotal Application Service</a> (PAS) |         |          |      |          |
| Pivotal Cloud Foundry Services         | <a href="#">MySQL v2</a>                          |         |          |      |          |
|                                        | <a href="#">Redis</a>                             |         |          |      |          |
|                                        | <a href="#">RabbitMQ</a>                          |         |          |      |          |
|                                        | <a href="#">Single Sign On</a> (SSO)              |         |          |      |          |
|                                        | <a href="#">Spring Cloud Services</a>             |         |          |      |          |
|                                        | <a href="#">Concourse</a>                         |         |          |      |          |
|                                        | ...                                               |         |          |      |          |
| Pivotal Cloud Foundry Partner Services | <a href="#">New Relic</a>                         |         |          |      |          |
|                                        | ...                                               |         |          |      |          |

### Upgrade Services Tiles

Upgrade all service tiles to versions that are compatible with PCF v2.2. Service tiles are add-on products you install alongside your runtime. For example, MySQL for PCF, PCF Healthwatch, and RabbitMQ are service tiles.

Do not upgrade runtime tiles, such as PAS, PAS for Windows (PASW), or Pivotal Container Service (PKS), at this time.

Review the [Compatibility Matrix](#) and tile documentation to check version compatibility.

## Configure BOSH Director

With each release of a new PCF version, BOSH Director may require specific updates before upgrading to the new version. See the following sections for what action to take before upgrading to PCF v2.2:

1. If you disabled BOSH DNS, reenable it. In the **Director Config** pane of the **BOSH Director** tile, clear the **Disable BOSH DNS server for troubleshooting purposes** checkbox.
2. Check the required machine specifications for Ops Manager v2.2. These specifications are specific to your IaaS. If these specifications do not match your existing Ops Manager, modify the values of your Ops Manager VM instance. For example, if the boot disk of your existing Ops Manager is 50 GB and the new Ops Manager requires 100 GB, then increase the size of your Ops Manager boot disk to 100 GB.

## Disable Unused Errands

To save upgrade time, you can disable unused PAS post-deploy errands. See the [Post-Deploy Errands](#) section of the Errands topic for details. Only disable these errands if your environment does not need them.

In some cases, if you have previously disabled lifecycle errands for any installed product to reduce deployment time, you may want to re-enable these errands before upgrading. For more information, see the [Adding and Deleting Products](#) topic.

## Check OS Compatibility of PCF and BOSH-Managed Add-Ons

Before upgrading to PCF v2.2, operators who have deployed any PCF add-ons such as **IPsec for PCF**, **ClamAV for PCF**, or **File Integrity Monitoring for PCF** and who have deployed or are planning to deploy [PAS for Windows 2012R2](#) must modify the add-on manifest to specify a compatible OS stemcell.

For example, **File Integrity Monitor for PCF** (FIM) is not supported on Windows. Therefore, the manifest must use an `include` directive to specify the target OS stemcell of `ubuntu-trusty`.

To update an add-on manifest, do the following:

1. Locate your existing add-on manifest file. For example, for FIM, locate the `fim.yml` you uploaded to the Ops Manager VM.
2. Modify the manifest to include following `include` directive to your manifest:

```
include:
 stemcell:
 - os: ubuntu-trusty
```

- a. Re-upload the manifest file to your PCF deployment. For example instructions, see [Create the FIM Manifest](#).

If you are using any other BOSH-managed add-ons in your deployment, you should verify OS compatibility for those component as well. For more information about configuring BOSH add-on manifests, see the [BOSH documentation](#).

## Check Backup and Restore External Blobstore Add-On

If you have enabled external blobstore backups for an Azure Blobstore using the [Blobstore Add-On](#), you need to update your runtime configuration to remove the `sdk-preview` add-on before upgrading to PCF v2.2. If you do not remove this job, upgrading PAS fails with the error:

```
Preparing deployment: Preparing deployment (00:00:01)
L Error: Colocated job 'azure-blobstore-backup-restorer' is already added to the instance group 'backup-restore'.
```

After removing this job from your runtime configuration, ensure that the **Enable backup and restore** checkbox is enabled in the PAS tile > **File Storage** pane. See [External Azure Storage](#) for instructions.

## Check Certificate Authority Expiration Dates

Depending on the requirements of your deployment, you may need to rotate your Certificate Authority (CA) certificates. The non-configurable certificates in your deployment expire every two years. You must regenerate and rotate them so that critical components do not face a complete outage.

 **Note:** PCF uses SHA-2 certificates and hashes by default. You can convert existing SHA-1 hashes into SHA-2 hashes by rotating your Ops Manager certificates using the procedure described in the [Regenerating and Rotating Non-Configurable TLS/SSL Certificates](#) section of *Managing TLS Certificates*.

To retrieve information about all the RSA and CA certificates for the BOSH Director and other products in your deployment, you can use the `GET /api/v0/deployed/certificates?expires_within=TIME` request of the Ops Manager API.

In this request, the `expires_within` parameter is optional. Valid values for the parameter are `d` for days, `w` for weeks, `m` for months, and `y` for years. For example, to search for certificates expiring within one month, replace `TIME` with `1m`:

```
$ curl "https://OPS-MAN-FQDN/api/v0/deployed/certificates?expires_within=1m" \
-X GET \
-H "Authorization: Bearer UAA_ACCESS_TOKEN"
```

For information about regenerating and rotating CA certificates, see [Managing TLS Certificates](#).

## Check the Capacity of Your Deployment

The following sections describe steps for ensuring your deployment has adequate capacity to perform the upgrade.

### Confirm Adequate Disk Space

Confirm that you have adequate disk space for your upgrades. You need at least 20 GB of free disk space to upgrade PCF Ops Manager and Pivotal Application Service. If you plan to upgrade other products, the amount of disk space required depends on how many tiles you plan to deploy to your upgraded PCF deployment.

To check current persistent disk usage, select the **BOSH Director** tile from the **Installation Dashboard**. Select **Status** and review the value of the 

|               |
|---------------|
| PERS.<br>DISK |
|---------------|

 column. If persistent disk usage is higher than 50%, select **Settings > Resource Config**, and increase your persistent disk space to handle the size of the resources. If you do not know how much disk space to allocate, set the value to at least `100 GB`.

### Check Diego Cell RAM and Disk

Check that Diego cells have sufficient available RAM and disk capacity to support app containers.

The KPIs that monitor these resources are:

- `rep.CapacityRemainingMemory`
- `rep.CapacityRemainingDisk`

### Adjust Diego Cell Limits

If needed, adjust the maximum number of Diego cells that the platform can upgrade simultaneously, to avoid overloading the other cells. See [Managing Diego Cell Limits During Upgrade](#).

For PCF v1.10 and later, the maximum number of cells that can update at once, `max_in_flight` is 4%. This setting is configured in the BOSH manifest's Diego cell definition. See the [Preventing Overload](#) section for details.

Review the [Diego Cell Metrics](#) section of the KPI topic for more information about these KPIs.

## Review File Storage IOPS and Other Upgrade Limiting Factors

During the PCF upgrade process, a large quantity of data is moved around on disk.

To ensure a successful upgrade of PCF, verify that your underlying PAS file storage is performant enough to handle the upgrade. For more information about the configurations to evaluate, see [Upgrade Considerations for Selecting Pivotal Cloud Foundry Storage](#).

In addition to file storage IOPS, consider additional existing deployment factors that can impact overall upgrade duration and performance:

| Factor                                         | Impact                                                                                                                                                 |
|------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| Network latency                                | Network latency can contribute to how long it takes to move app instance data to new containers.                                                       |
| Number of ASGs                                 | A large number of <a href="#">Application Security Groups</a> in your deployment can contribute to an increase in app instance container startup time. |
| Number of app instances and application growth | A large increase in the number of app instances and average droplet size since the initial deployment can increase the upgrade impact on your system.  |

To review example upgrade-related performance measurements of an existing production Cloud Foundry deployment, see the [Pivotal Web Services Performance During Upgrade](#) topic.

## Run BOSH Clean-Up

Run `bosh -e ALIAS clean-up --all` to clean up old stemcells, releases, orphaned disks, and other resources before upgrade. This cleanup helps prevent the product and stemcell upload process from exceeding the BOSH Director's available persistent disk space.

## Check the Health of Your Deployment

The following sections describe steps for ensuring your deployment is healthy before you perform the upgrade.

### Collect Foundation Health Status

For collecting foundation health status, Pivotal recommends PCF Healthwatch, which monitors and alerts on the current health, performance, and capacity of PCF. For more information, see the [PCF Healthwatch documentation](#).

If you are not using PCF Healthwatch, you can do some or all of the following to collect foundation health status:

- If your PCF deployment has external metrics monitoring set up, verify that VM CPU, RAM, and disk use levels are within reasonable levels.
- Run BOSH CLI commands to check system status:
  - `bosh -e ALIAS -d DEPLOYMENT_NAME instances --ps`.  
`bosh instances` with the flags `--ps`, `--vitals`, or `--failing` highlights individual job failure.
  - `bosh -e ALIAS vms --vitals`. This reveals VMs with high CPU, high memory, high disk utilization, and with `state != running`.
  - `bosh -e ALIAS -d DEPLOYMENT_NAME cck --report`
- Check Ops Manager GUI each PAS/Tiles the status page for CPU/RAM/DISK utilization
- Validate Ops Manager persistent disk usage is below 50%. If not, follow the procedure in [Confirm Adequate Disk Space](#).

(Optional) Check the logs for errors before proceeding with the upgrade. For more information, see [Viewing Logs in the Command Line Interface](#).

## Push and Scale a Test App

Check that a test app can be pushed and scaled horizontally, manually or through automated testing. This check ensures that the platform supports apps as expected before the upgrade.

## Validate Installed Buildpacks

Buildpacks may now have an [associated stack](#) denoting which stacks they are compatible with. During this transition, PAS will begin installing multiple versions of buildpacks for different stacks (e.g. `cflinuxfs2`, `cflinuxfs3`, etc.). To ensure that the buildpacks are [installed without errors](#), if you have multiple buildpacks installed with the same name all buildpacks with that name must be associated with a stack. Additionally, any buildpacks that do not

have an associated stack should be unlocked prior to upgrading. Refer to the [following documentation](#) for more information on associating a stack with an existing buildpack.

## Validate MySQL Cluster Health

If you are running PAS MySQL as a cluster, run the `mysql-diag` tool to validate health of the cluster.

See the BOSH CLI v2 instructions in the [Running mysql-diag](#) topic.

## Review Pending and Recent Changes

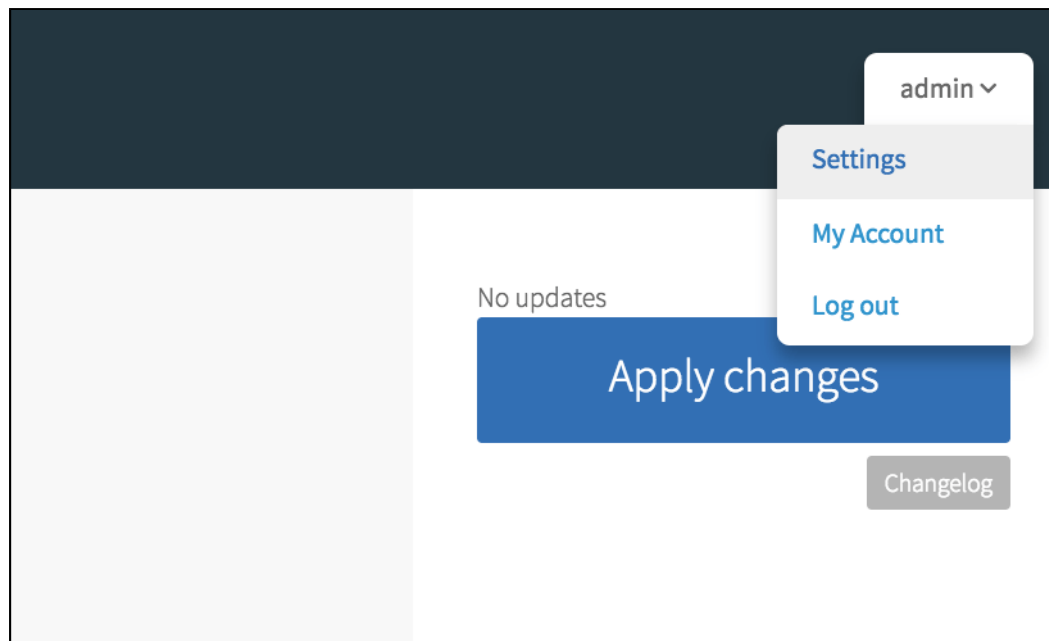

1. Confirm there are no outstanding changes in Ops Manager or any other tile. All tiles should be **green**. Click **Review Pending Changes**, then **Apply Changes** if necessary.
2. After applying changes, click **Recent Install Logs** to confirm that the changes completed cleanly:

```
Cleanup complete
{"type": "step_finished", "id": "clean_up_bosh.cleaning_up"}
Exited with 0.
```

## Export Your Installation

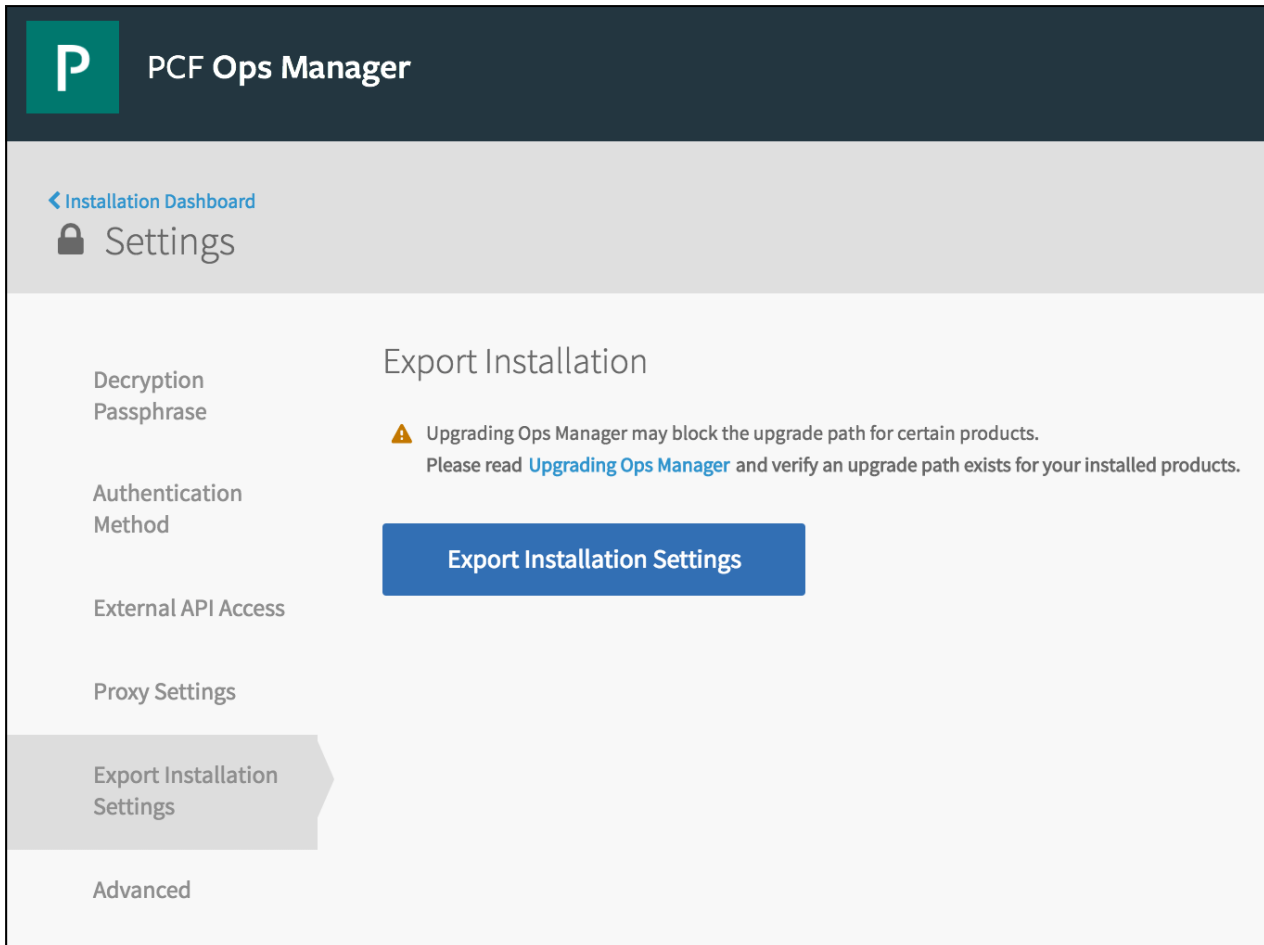

To export your installation, do the following:

1. In your Ops Manager v2.1 **Installation Dashboard**, click the account dropdown and select **Settings**.

2. On the **Settings** screen, select **Export Installation Settings** from the left menu, then click **Export Installation Settings**.

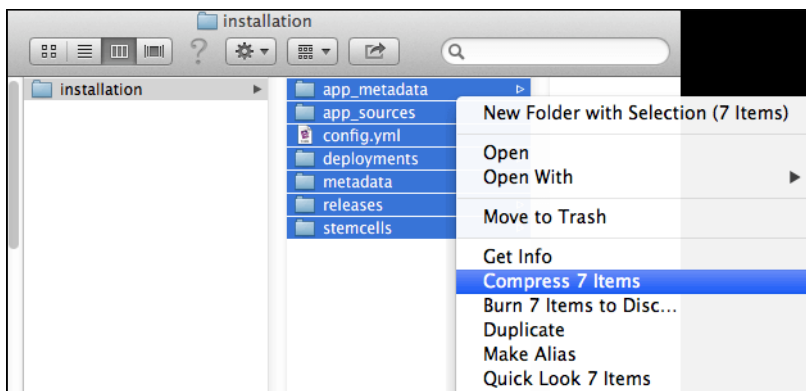

This exports the current PCF installation with all of its assets.

When you export an installation, the export contains the base VM images, necessary packages, and configuration settings, but does not include releases between upgrades if Ops Manager has already uploaded them to BOSH. When backing up PCF, you must take this into account by backing up the BOSH blobstore that contains the uploaded releases. BOSH Backup and Restore (BBR) backs up the BOSH blobstore. For more information, see [Backing Up Pivotal Cloud Foundry with BBR](#).

- The export time depends on the size of the exported file.
- Some browsers do not provide feedback on the status of the export process and might appear to hang.

**Note:** Some operating systems automatically unzip the exported installation. If this occurs, create a ZIP file of the unzipped export. Do not start compressing at the “installation” folder level. Instead, start compressing at the level containing the `config.yml` file:

**Warning:** If you fail to perform the remedial steps for this issue, this upgrade process may corrupt your existing usage data.

## Next Steps

Now that you have completed the Upgrade Preparation Checklist for PCF v2.2, continue to [Upgrading Pivotal Cloud Foundry](#).

## Complete Survey

Please take some time to help us improve this document by completing the [Upgrade Checklist Survey](#) [↗](#).

## Configuring PAS for Upgrades

This topic describes several configuration options for Pivotal Application Service (PAS) that can help ensure successful upgrades. In addition to following the [Upgrade Preparation Checklist](#), review the sections in this document to better understand how to prepare for PAS Upgrades.

### Limit PCF Component Instance Restarts

The `max_in_flight` variable limits how many instances of a component can restart simultaneously during updates or upgrades. Increasing the value of `max_in_flight` can make updates run faster, but setting it too high risks overloading VMs and causing failure. See [Best Practices](#) for guidance on setting `max_in_flight` values.

Values for `max_in_flight` can be any integer between 1 and 100, or a percentage of the total number of instances. For example, a `max_in_flight` value of `20%` in a deployment with 10 Diego cell instances would make no more than two cell instances restart at once.

### Set max\_in\_flight

The `max_in_flight` variable is a system-wide value with optional component-specific overrides. You can override the default value for individual jobs using an API endpoint.

#### Use the max\_in\_flight API Endpoint

Use the `max_in_flight` API endpoint to configure the maximum value for component instances that can start at a given time. This endpoint overrides product defaults. You can specify values as a percentage or an integer.

Use the string “default” as the `max_in_flight` value to force the component to use the deployment’s default value.

**Note:** The example below lists three JOB\_GUIDs. These three GUIDs are examples of the three different types of values you can use to configure `max_in_flight`. The endpoint only requires one GUID.

```
curl "https://EXAMPLE.com/api/v0/staged/products/PRODUCT-TYPE1-GUID/max_in_flight" \
-X PUT \
-H "Authorization: Bearer UAA_ACCESS_TOKEN" \
-H "Content-Type: application/json" \
-d '{
 "max_in_flight": {
 "JOB_1_GUID": 1,
 "JOB_2_GUID": "20%",
 "JOB_3_GUID": "default"
 }
}'
```

### Specific Guidance for Diego Cells

To upgrade Cloud Foundry, BOSH must drain all Diego cell VMs that host app instances. BOSH manages this process by upgrading a batch of cells at a time.

The number of cells that undergo upgrade simultaneously (either in a state of shutting down or coming back online) is controlled by the `max_in_flight` value of the Diego cell job. For example, if `max_in_flight` is set to `10%` and your deployment has 20 Diego cell job instances, then the maximum number of cells that BOSH can upgrade at a single time is `2`.

When BOSH triggers an upgrade, each Diego cell undergoing upgrade enters “evacuation” mode. Evacuation mode means that the cell stops accepting new work and signals the rest of the Diego system to schedule replacements for its app instances. This scheduling is managed by the [Diego auctioneer process](#).

The evacuating cells continue to interact with the Diego system as replacements come online. The cell undergoing upgrade waits until either its app instance replacements run successfully before shutting down the original local instances, or for the evacuation process to time out. This “evacuation timeout” defaults to 10 minutes.

If cell evacuation exceeds this timeout, then the cell stops its app instances and shuts down. The Diego system continues to re-emit start requests for the

app replacements.

## Prevent Overload

A potential issue arises if too many app instance replacements are slow to start or do not start successfully at all.

If too many app instances are starting concurrently, then the load of these starts on the rest of the system can cause other applications that are already running to crash and be rescheduled. These events can result in a cascading failure.

To prevent this issue, PCF provides two throttle configurations: the maximum number of in-flight diego cell instances and the maximum number of starting containers.

The values of the above throttle configurations depend on the version of PCF that you have deployed and whether you have overridden the default values.

Refer to the following table for existing defaults and, if necessary, determine the override values in your deployment.

| PCF Version            | Starting Container Count Maximum | Starting Container Count Overridable? | Maximum In Flight Diego Cell Instances | Maximum In Flight Diego Cell Instances Overridable? |
|------------------------|----------------------------------|---------------------------------------|----------------------------------------|-----------------------------------------------------|
| PCF 1.7.43 and earlier | No limit set                     | No                                    | 1 instance                             | No                                                  |
| PCF 1.7.44 to 1.7.49   | 200                              | No                                    | 1 instance                             | No                                                  |
| PCF 1.7.50 +           | 200                              | No                                    | 1 instance                             | No                                                  |
| PCF 1.8.0 to 1.8.29    | No limit set                     | No                                    | 10% of total instances                 | No                                                  |
| PCF 1.8.30 +           | 200                              | Yes                                   | 10% of total instances                 | No                                                  |
| PCF 1.9.0 to 1.9.7     | No limit set                     | No                                    | 4% of total instances                  | Yes                                                 |
| PCF 1.9.8 +            | 200                              | Yes                                   | 4% of total instances                  | Yes                                                 |
| PCF 1.10.0 and later   | 200                              | Yes                                   | 4% of total instances                  | Yes                                                 |
| PCF 1.12.0 and later   | 200                              | Yes                                   | 4% of total instances                  | Yes                                                 |

## Best Practices

Set the `max_in_flight` variable high enough that the remaining component instances are not overloaded by typical use. If component instances are overloaded during updates, upgrades, or typical use, users may experience downtime.

Some more precise guidelines include:

- For jobs with high resource usage, set `max_in_flight` low. For example, for Diego cells, `max_in_flight` allows non-migrating cells to pick up the work of cells stopping and restarting during migration. If resource usage is already close to 100%, scale up your jobs before making any updates.
- For quorum-based components (these are components with odd-numbered settings in the manifest), such as etcd, consul, and Diego BBS, set `max_in_flight` to 1. This preserves quorum and prevents a [split-brain scenario](#) from occurring as jobs restart.
- For other components, set `max_in_flight` to the number of instances that you can afford to have down at any one time. The best values for your deployment vary based on your capacity planning. In a highly redundant deployment, you can make the number high so that updates run faster. If your components are at high utilization, however, you should keep the number low to prevent downtime.
- Never set `max_in_flight` to a value greater than or equal to the number of instances you have running for a component.

## Set a Maximum Number of Starting Containers

This section describes how to use the auctioneer job to configure the maximum number of app instances starting at a given time. This prevents Diego from scheduling too much new work for your platform to handle concurrently. A lower default can prevent server overload during cold start, which may be important if your infrastructure is not sized for a large number of concurrent cold starts.

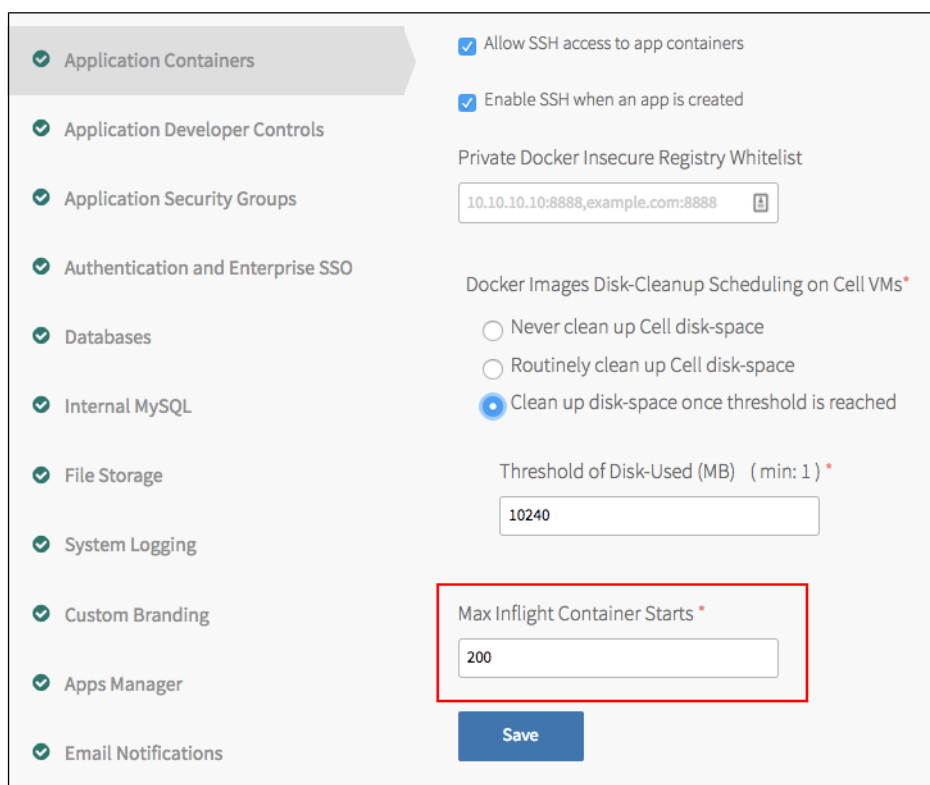

The auctioneer only schedules a fixed number of app instances to start concurrently. This limit applies to both single and multiple Diego Cells. For

example, if you set the limit to five starting instances, it does not matter if you have one Diego Cell with ten instances or five Diego Cells with two instances each. The auctioneer will not allow more than five instances to start at the same time.

If you are using a cloud-based IaaS, rather than a smaller on-premise solution, Pivotal recommends setting a larger default. By default, the maximum number of started instances is 200.

You can configure the maximum number of started instances in the Settings tab of the Pivotal Application Service (PAS) tile.

1. Log in to Operations Manager.
2. Click the PAS tile.
3. Click **Application instances** in the sidebar.
4. In the Max Inflight Container Starts field, type the maximum number of started instances.

The screenshot shows the 'Application Containers' settings page. On the left, a sidebar lists settings categories: Application Containers (selected), Application Developer Controls, Application Security Groups, Authentication and Enterprise SSO, Databases, Internal MySQL, File Storage, System Logging, Custom Branding, Apps Manager, and Email Notifications. The main content area includes checkboxes for 'Allow SSH access to app containers' and 'Enable SSH when an app is created', both checked. Below these is a 'Private Docker Insecure Registry Whitelist' field containing '10.10.10.10:8888,example.com:8888'. Further down is a section for 'Docker Images Disk-Cleanup Scheduling on Cell VMs\*' with three radio button options: 'Never clean up Cell disk-space', 'Routinely clean up Cell disk-space', and 'Clean up disk-space once threshold is reached' (selected). Below this is a 'Threshold of Disk-Used (MB) (min: 1) \*' field with the value '10240'. At the bottom, a red box highlights the 'Max Inflight Container Starts \*' field, which contains the value '200'. A 'Save' button is located at the bottom right of the settings area.

5. Click **Save**.

## Configure File Storage

This section describes critical factors to consider when evaluating the type of file storage to use in your Pivotal Cloud Foundry (PCF) deployment. The [Pivotal Application Service \(PAS\) blobstore](#) relies on the file storage system to read and write resources, app packages, and droplets.

During an upgrade of PCF, file storage with insufficient IOPS numbers can negatively impact the performance and stability of your PCF deployment.

If disk processing time takes longer than the evacuation timeout for Diego cells, then Diego cells and app instances may take too long to start up, resulting in a cascading failure.

However, the minimum required IOPS depends upon a number of deployment-specific factors and configuration choices. Use this section as a guide when deciding on the file storage configuration for your deployment.

To see an example of system performance and IOPS load during an upgrade, refer to [Upgrade Load Example: Pivotal Web Services](#).

## Select Internal or External File Storage

When you deploy PCF, you can select internal file storage or external file storage, either network-accessible or IaaS-provided, as an option in the PAS

tile.

Selecting internal storage causes PCF to deploy a dedicated virtual machine (VM) that uses either NFS or WebDAV for file storage. Selecting external storage allows you to configure file storage provided in network-accessible location or by an IaaS, such as Amazon S3, Google Cloud Storage, or Azure Storage.

Whenever possible, Pivotal recommends using external file storage.

## Calculate Potential Disk Load Requirements

As a best-effort calculation, estimate the total number of bits needed to move during a system upgrade to determine how IOPS-performant your file storage needs to be.

### ◦ Number of Diego Cells

- As a first calculation, determine the number of Diego cells that your deployment currently uses. To view the number of Diego cell instances currently running in your deployment, see the **Resource Config** section of your PAS tile. If you expect to scale up the number of instances, use the anticipated scaled number.

 **Note:** If your deployment uses more than 20 Diego cells, you should avoid using internal file storage. Instead, you should always select external or IaaS-provided file storage.

### ◦ Maximum In-Flight Load and Container Starts for Diego Cells

- Operators can limit the number of containers and Diego cell instances that Diego starts concurrently. If operators impose no limits, your file storage may experience exceptionally heavy load during an upgrade.

## Upgrade Load Example: Pivotal Web Services

Page last updated:

This topic provides sample performance measurements of a Cloud Foundry installation undergoing the workload associated with an upgrade.

To obtain these measurements, Pivotal repaved its production Pivotal Web Services (PWS) deployment. The repave process simulates system load that would be incurred when performing a rolling upgrade of Diego cells.

Use the measurements and configuration values published in this document as guidance when ensuring you have adequate file storage hardware prior to a platform upgrade.

For more information about the impact of upgrade on file storage performance, see [Upgrade Considerations for Selecting File Storage in Pivotal Cloud Foundry](#).

## Platform Configuration

The following table details the starting parameters and configuration of PWS.

| Configuration                                | Value                                         | How to Locate                                                                                                                                                                                                                                |
|----------------------------------------------|-----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IaaS                                         | Amazon Web Services                           | Refer to your BOSH Director configuration or BOSH deployment manifest.                                                                                                                                                                       |
| File Storage                                 | AWS EBS (External with some elastic capacity) | Refer to your Pivotal Application Service (PAS) configuration or BOSH deployment manifest.                                                                                                                                                   |
| Version of CF                                | v252                                          | Refer to your BOSH Director and PAS configuration or BOSH deployment manifest.                                                                                                                                                               |
| Number of Diego Cells                        | 218                                           | To view the number of Diego cell instances currently running in your deployment, see the <b>Resource Config</b> section of your PAS tile or consult your Diego deployment manifest.                                                          |
| Maximum Number of Started Containers         | 250                                           | See <a href="#">PCF</a> documentation for configuration information.                                                                                                                                                                         |
| max_in_flight Configuration for Diego Cells  | 6                                             | To retrieve the existing <code>max_in_flight</code> value for the Diego Cell job in BOSH Director, use the Ops Manager API. See the Ops Manager API documentation. If you are running open source CF, consult your BOSH deployment manifest. |
| Number of Availability Zones (AZ)            | 2                                             | Consult your PAS or BOSH deployment AZ configuration.                                                                                                                                                                                        |
| Number of App Instances                      | 16231                                         | <code>datadog.nozzle.bbs.LRPsRunning</code>                                                                                                                                                                                                  |
| Number of Application Security Groups (ASGs) | 43                                            | As admin user, run the <code>cf security-groups</code> command. For more information, see <a href="#">Application Security Groups</a> .                                                                                                      |

## System Performance Measurements During Cell Repave

This table presents performance measurements taken during the Diego cell repave.

 **Note:** These measurements indicate the peak cumulative values of the entire system (250 Diego cells, ~15,000 application instances, and 2 AZs.)

Use these measurements as a baseline for expected system load during Diego cell upgrade.

| Measurement             | Value | Metric Used                                           |
|-------------------------|-------|-------------------------------------------------------|
| Cell CPU Consumption    | 36%   | <code>bosh.healthmonitor.system.cpu.usage</code>      |
| Cell Memory Consumption | ~50%  | <code>bosh.healthmonitor.system.memory.percent</code> |

|                                                                 |                                             |                                       |
|-----------------------------------------------------------------|---------------------------------------------|---------------------------------------|
| Cell I/O Consumption (Read) During Normal Operations            | 43 Read I/O Operations per second           | <code>aws.ebs.volume_read_ops</code>  |
| Cell I/O Consumption (Read) During Upgrade                      | 1,943 Read I/O Operations per second        | <code>aws.ebs.volume_read_ops</code>  |
| Cell IO Consumption (Write) During Normal Operations            | 2,166 Write I/O Operations per second       | <code>aws.ebs.volume_write_ops</code> |
| Cell IO Consumption (Write) During Upgrade                      | 21,000 Write I/O Operations per second      | <code>aws.ebs.volume_write_ops</code> |
| Cell Network Consumption (Network Out) During Normal Operations | ~1.25 GB per minute                         | <code>aws.ec2.network_out</code>      |
| Cell Network Consumption (Network Out) During Upgrade           | ~1.25 GB per minute (no significant change) | <code>aws.ec2.network_out</code>      |
| Cell Network Consumption (Network In) During Normal Operations  | 2.11 GB per minute                          | <code>aws.ec2.network_in</code>       |
| Cell Network Consumption (Network In) During Upgrade            | 16.75GB per minute                          | <code>aws.ec2.network_in</code>       |

## Sample Performance Graphs

These DataDog graphs represent a timeline visualization of read and write operations during the repave event.

### Read I/O Operations

The read I/O operations sample was taken over 115 VMs and represent the number of read operations over 300 seconds for a single Diego cell.

### Write I/O Operations

The write I/O operations sample was taken over 115 VMs and represent the number of read I/O operations over 300 seconds for a single Diego cell.

## Summary

During the repave process, 250 Diego cells were updated. The repave process took 6 hours overall or about 3 hours for each Availability Zone.

## Upgrading PAS and Other Pivotal Cloud Foundry Products

Page last updated:

This topic describes how to upgrade to a point release of Pivotal Application Service (PAS) and other product tiles without upgrading Ops Manager. For example, use this topic to upgrade from PAS v2.2.0 to v2.2.1. You might need to perform this upgrade if a security update for PAS is released, or if new features are introduced in a point release of a product tile.

For PAS component and version information, see the [PAS release notes](#).

**Note:** If you cannot download products from Pivotal Network due to restricted network connectivity, see [Installing PCF in Airgapped Environments](#).

### Before You Upgrade to Point Releases

- You must have completed the [Upgrading Pivotal Cloud Foundry](#) procedure.
- Refer to the [Product Compatibility Matrix](#) before upgrading PAS.
- Important:** Read the Known Issues sections of the products you plan on installing before starting. See [Pivotal Cloud Foundry Release Notes](#) for all available product release notes.

### Upgrading PAS

**Note:** If you are using the [Pivotal Network API](#), the latest product versions will automatically appear in your **Installation Dashboard**.

To upgrade PAS without upgrading Ops Manager, do the following:

- Download the product file from [Pivotal Network](#).
- Import the product file to your Ops Manager **Installation Dashboard**.
- Click the plus icon next to the uploaded product description to add this product to your staging area.
- Click the newly added tile to review any configurable options.
- Click **Apply Changes** to install the service.

### Upgrading PCF Products

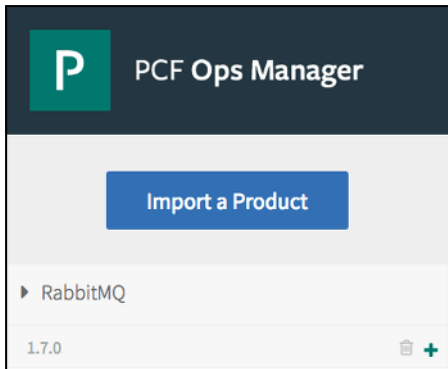

**Note:** If you are using the [Pivotal Network API](#), the latest product versions will automatically appear in your **Installation Dashboard**.

This section describes how to upgrade individual products like [Single Sign-On for PCF](#), [MySQL for PCF](#), [RabbitMQ® for PCF](#), and [Metrics for PCF](#) in your Pivotal Cloud Foundry (PCF) deployment. Ensure you review the individual product upgrade procedure for each tile.

- Browse to [Pivotal Network](#) and sign in.
- Download the latest PCF release for the product or products you want to upgrade. Every product is tied to exactly one stemcell. Download the stemcell that matches your product and version.
- Confirm that you have adequate disk space for your upgrades. You need at least 20 GB of free disk space to upgrade PCF Ops Manager and Pivotal Application Service. If you plan to upgrade other products, the amount of disk space required depends on how many tiles you plan to deploy to your upgraded PCF deployment.

To check current persistent disk usage, select the **BOSH Director** tile from the **Installation Dashboard**. Select **Status** and review the value of the **PERS. DISK** column. If persistent disk usage is higher than 50%, select **Settings > Resource Config**, and increase your persistent disk space to handle the size of the resources. If you do not know how much disk space to allocate, set the value to at least **100 GB**.

- Browse to the Pivotal Cloud Foundry Ops Manager web interface and click **Import a Product**.

5. Select the `.pivotal` file that you downloaded from Pivotal Network or received from your software distributor, then click **Open**. If the product is successfully added, it appears in your product list. If the product you selected is not the latest version, the most up-to-date version will appear on your product list.
6. Click the plus icon next to the product description to add the product tile to the **Installation Dashboard**.
7. Repeat the import, upload, and upgrade steps for each product you downloaded.
8. If you are upgrading a product that uses a self-signed certificate from v1.1 to v1.2, you must configure the product to trust the self-signed certificate. To configure a product to trust the self-signed certificate, do the following:
  - a. Click the product tile.
  - b. In the left-hand column, select the setting page containing the SSL certificate configuration. For example, for PAS, select the **HAProxy** page.
  - c. Check the **Trust Self-Signed Certificates** box.
  - d. Click **Save**.
9. Click **Apply Changes**.

## Upgrading Replicated Tiles

To upgrade a replicated tile, you must do the following:

- Generate a replica of the newer version of the tile using the replicator
- Give the new replica the same name as the existing replica.

See the following example workflow.

### Example Workflow

This example assumes the following:

- You used the replicator to generate a replica of v1 of the Isolation Segments tile.
- You used the `name` **seg-one**.
- You installed the tile in Ops Manager.

Here is the sample replicator command you used for the initial installation:

```
./replicator-darwin\
--name seg-one\
--path /download/p-isolation-segment-v1.pivotal\
--output /output/p-isolation-segment-v1-seg-one.pivotal
```

To upgrade to v2, follow these steps:

1. Download and unzip the new Isolation Segment Tile Replicator from [Pivotal Network](#). You must download the version of Tile Replicator that corresponds with the version of the Isolation Segment Tile you want to replicate.
2. Run the replicator command below to create the replica:

```
./replicator-darwin\
--name NAME-OF-EXISTING-REPLICA \
--path PATH-TO-NEW-TILE \
--output /output/p-isolation-segment-v2-seg-one.pivotal
```

Where:

- `NAME-OF-EXISTING-REPLICA` must be the same as the name used for the existing replica. This is **seg-one** in this example.
- `PATH-TO-NEW-TILE` is the path to the new Isolation Segment Tile.

3. After you have the replica tile **p-isolation-segment-v2-seg-one.pivotal**, upload it to Ops Manager. This upgrades the v1 replica tile in place.

## cf push Availability During Pivotal Application Service Upgrades

Page last updated:

This topic describes what you can expect regarding the availability of `cf push` during upgrades of Pivotal Application Service (PAS).

### Overview

Availability of `cf push` during PAS upgrades varies from release to release. There are various considerations, such as Cloud Controller database (CCDB) migrations or the number of VMs in use, that can impact `cf push` availability. However, `cf push` is mostly available for the duration of an upgrade.

### Impact on Single VMs vs. High-Availability Infrastructure

Having a single VM in use, such as a WebDAV, a HAProxy, a Gorouter, a UAA, or a Cloud Controller, impacts whether `cf push` is unavailable during an upgrade.

If you have scaled out your application to achieve high availability and are not using WebDAV, `cf push` should be available for the entire duration of the upgrade. However, upgrades to certain versions of PAS sometimes require a CCDB schema or data migration, which may cause `cf push` to be unavailable while Cloud Controllers are rolling during the upgrade.

### Availability During a BBR Backup

The Cloud Controller API is taken down during the `pre-backup-lock` stage of a BBR backup and put back up again during the `post-backup-unlock` stage. As a result, `cf push` becomes unavailable during that time. However, the backup that takes place between those stages is very short, no longer than a few minutes. The bulk of the BBR backup operation happens after the `post-backup-unlock` stage, so the Cloud Controller API and `cf push` are available for most of the duration of a BBR backup.

The [Uptimer](#) [↗](#) tool can help you measure `cf push` availability during an upgrade.

## PCF Dev Overview

Page last updated:

This guide describes how to install and use PCF Dev, a fully featured Pivotal Cloud Foundry (PCF) installation that runs on your workstation's native hypervisor.

PCF Dev enables application developers to test and debug their app on a local PCF deployment, and enables operators to test out features of PCF in their local environment.

PCF Dev includes Pivotal Application Service (PAS), Spring Cloud Services, Redis, RabbitMQ, and MySQL. It also supports all Cloud Foundry Command Line Interface (cf CLI) functionality. See the [Comparing PCF Dev to Pivotal Cloud Foundry](#) table below for more product details.

## Prerequisites

Before you can install PCF Dev, you must have the following:

- The latest version of the [cf CLI](#): Use the cf CLI to push and scale apps.
- You must have an Internet connection for DNS.
- At least 8 GB of available memory on your host machine. Pivotal recommends running on a host system with at least 16 GB of total RAM.
- Virtualization permissions.

## Comparing PCF Dev to Pivotal Cloud Foundry

PCF Dev mirrors [PCF](#) in its key product offerings. If an application runs on PCF Dev, it runs on PCF with no modification in almost all cases. Review the table below for key product details.

|                          | PCF Dev                   | PCF         | CF                           |
|--------------------------|---------------------------|-------------|------------------------------|
| Space required           | 100 GB                    | 100GB+      | 50GB+                        |
| Memory required          | 8 GB                      | 50GB+       | variable                     |
| Deployment               | <code>cf dev start</code> | Ops Manager | <code>bosh create-env</code> |
| Estimated time-to-deploy | 30 Minutes                | Hour+       | Hour+                        |

|                                                                            | Pivotal<br>CF Dev                 | Pivotal<br>CF                | CF  |
|----------------------------------------------------------------------------|-----------------------------------|------------------------------|-----|

## Backing Up and Restoring Pivotal Cloud Foundry

Page last updated:

Consider the following when backing up data in your Pivotal Cloud Foundry (PCF) deployment:

- If your deployment uses external databases, check that it is a [supported database configuration](#).
- If your PCF deployment uses internal databases, follow the backup and restore instructions for the MySQL server included in the [BBR](#) documentation.

### General Data Protection Regulation

The General Data Protection Regulation (GDPR) came into effect on May 25, 2018 and impacts any company processing the data of EU citizens or residents, even if the company is not EU-based. The GDPR sets forth how companies should handle privacy issues, securely store data, and respond to security breaches.

Backup artifacts may contain personal data covered by GDPR. For example, a backup of a PAS could contain a user email. For further information regarding personal data that may be stored in PCF, see [here](#).

## Backup and Restore with BBR

BOSH Backup and Restore (BBR) is a command-line tool for backing up and restoring BOSH deployments.

To perform a backup of your PCF deployment with BBR, see [Backing Up Pivotal Cloud Foundry with BBR](#).

To restore your PCF deployment with BBR, see [Restoring Pivotal Cloud Foundry from Backup with BBR](#).

To use BBR to back up and restore your PCF deployment, you must first set up a jumpbox to run BBR from. See [Setting Up Your Jumpbox for BBR](#).

To troubleshoot problems with BBR, see [Troubleshooting BBR](#).

## Disaster Recovery in Pivotal Cloud Foundry

This document provides an overview of the options and considerations for disaster recovery in Pivotal Cloud Foundry (PCF).

Operators have a range of approaches for ensuring they can recover Pivotal Cloud Foundry, apps, and data in case of a disaster. The approaches fall into the following two categories:

- Using data from a backup to restore the data in the PCF Deployment. See [Back up and Restore Using BOSH Backup and Restore \(BBR\)](#) for more information.
- Recreating the data in PCF by automating the creation of state in PCF. See [Disaster Recovery by Recreating the Deployment](#) for more information.

## Back up and Restore using BOSH Backup and Restore (BBR)

### What is BBR?

BOSH Backup and Restore (BBR) is a CLI for orchestrating backing up and restoring BOSH deployments and BOSH Directors. BBR triggers the backup or restore process on the deployment or Director, and transfers the backup artifact to and from the deployment or Director.

Use BOSH Backup and Restore to reliably create backups of core PCF components and their data. These core components include CredHub, UAA, BOSH Director, and PAS.

Each component includes its own backup scripts. This decentralized structure helps keep scripts synchronized with the components. At the same time, *locking* features ensure data integrity and consistent, distributed backups across your deployment.

For more information about the BBR framework, see [BOSH Backup and Restore](#) in the open source Cloud Foundry documentation.

### Backing up PCF

Backing up PCF requires backing up the following components:

- Ops Manager settings
- BOSH Director, including CredHub and UAA
- Pivotal Application Service
- Data services

For more information, see [Backing up Pivotal Cloud Foundry with BBR](#). With these backup artifacts, operators can recreate PCF exactly as it was when the backup was taken.

### Restoring PCF

The restore process involves creating a new PCF deployment starting with the Ops Manager VM. For more information, see [Restoring Pivotal Cloud Foundry from Backup with BBR](#).

The time required to restore the data is proportionate to the size of the data because the restore process includes copying data. For example, restoring a 1 TB blobstore takes one thousand times as long as restoring a 1 GB blobstore.

### Benefits

Unlike other backup solutions, using BBR to back up PCF enables the following:

- **Completeness:** BBR supports backing up BOSH, including releases, CredHub, UAA, and service instances created with an on-demand service broker. With PCF v1.12, Ops Manager export no longer includes releases.
- **Consistency:** BBR provides referential integrity between the database and the blobstore because a lock is held while both the database and blobstore are backed up.
- **Correctness:** Using the BBR restore flow addresses C2C and routing issues that can occur during restore.

## API Downtime During Backups

Apps are not affected during backups, but certain APIs are unavailable. The downtime occurs only while the backup is being taken, not while the backup is being copied to the jumpbox.

In a consistent backup, the blobs in the blobstore match the blobs in the Cloud Controller Database. To take a consistent backup, changes to the data are prevented during the backup. This means that the CF API, Routing API, Usage Service, Autoscaler, Notification Service, Network Policy Server, and CredHub are unavailable while the backup is being taken. UAA is in read-only mode during the backup.

## Backup Timings

The first three phases of the backup are lock, backup, and unlock. During this time, the API is unavailable. The drain and checksum phase starts once the backup scripts finish. BBR downloads the backup artifacts from the instances to the BBR VM, and performs a checksum to ensure the artifacts are not corrupt. The size of the blobstore significantly influences backup time.

The table below gives an indication of the downtime that you can expect. Actual downtime varies based on hardware and PCF configuration. These example timings were recorded with Pivotal Application Service (PAS) deployed on Google Cloud Platform (GCP) with all components scaled to one and only one app pushed.

| <i>Backup Timings</i> |                     |                                                                |                                                                  |                                        |
|-----------------------|---------------------|----------------------------------------------------------------|------------------------------------------------------------------|----------------------------------------|
| <i>API State</i>      | <i>Backup phase</i> | <i>Duration for External Versioned S3-Compatible Blobstore</i> | <i>Duration for External Unversioned S3-Compatible Blobstore</i> | <i>Duration for Internal Blobstore</i> |
| API unavailable       | lock                | 15 seconds                                                     | 15 seconds                                                       | 15 seconds                             |
|                       | backup              | <30 seconds                                                    | Proportional to blobstore size                                   | 10 seconds                             |
|                       | unlock              | 3 minutes                                                      | 3 minutes                                                        | 3 minutes                              |
| API available         | drain and checksum  | <10 seconds                                                    | <10 seconds                                                      | Proportional to blobstore size         |

## Blobstore backup and restore

Blobstores can be very large. To minimize downtime, BBR only takes blob metadata during the backup. For example, in the case of internal blobstores (Webdav/NFS), BBR takes a list of hardlinks that point to the blobs. Once the API becomes available, BBR makes copies of the blobs.

## Unsupported Products

- **Data services.** The Pivotal data services listed below do not support BBR. Operators of these services should use the automatic backups feature of each tile, available within Ops Manager.
  - MySQL for PCF
  - Pivotal Cloud Cache for PCF
  - RabbitMQ for PCF
  - Redis for PCF
- **External blobstores and databases.** BBR support for backing up and restoring external databases and blobstores varies across PCF versions. For more information, see [Supported Components](#) and [External Storage Support Across PCF Versions](#) in *Backing up Pivotal Cloud Foundry with BBR*.

## Best Practices

### Frequency of Backups

Pivotal recommends that you take backups in proportion to the rate of change of the data in PCF to minimize the number of changes lost if a restore is required. We suggest starting with backing up every 24 hours. If app developers make frequent changes, you should increase the frequency of backups.

### Retention of Backup Artifacts

Operators should retain backup artifacts based on the timeframe they need to be able to restore to. For example, if backups are taken every 24 hours and

PCF must be able to be restored to three days prior, three sets of backup artifacts should be retained.

Artifacts should be stored in two data centers other than the PCF data center. When deciding the restore timeframe, you should take other factors such as compliance and auditability into account.

## Security

Pivotal strongly recommends that you encrypt artifacts and stored them securely.

## Disaster Recovery by Recreating the Deployment

An alternative strategy for recovering PCF after a disaster is to have automation in place so that all the data can be recreated. This requires that every modification to PCF settings and state be automated, typically through use of a pipeline.

Recovery steps include creating a new PCF, recreating orgs, spaces, users, services, service bindings and other state, and re-pushing apps.

For more information about this approach, see the following Cloud Foundry Summit presentation: [Multi-DC Cloud Foundry: What, Why and How? ↗](#).

## Disaster Recovery for Different Topologies

### Active-Active

To prevent app downtime, some Pivotal customers run active-active, where they run two or more identical PCF deployments in different data centers. If one PCF deployment becomes unavailable, traffic is seamlessly routed to the other deployment. To achieve identical deployments, all operations to PCF are automated so they can be applied to both PCF deployments in parallel.

Because all operations have been automated, the automation approach to disaster recovery is a viable option for active-active. Disaster recovery requires recreating PCF, then running all the automation to recreate state.

This option requires discipline to automate all changes to PCF. Some of the operations that need to be automated are the following:

- App push, restage, scale
- Org, space, and user create, read, update, and delete (CRUD)
- Service instance CRUD
- Service bindings CRUD
- Routes CRUD
- Security groups CRUD
- Quota CRUD

Human-initiated changes always make their way into the system. These changes can include quotas being raised, new settings being enabled, and incident responses. For this reason, Pivotal recommends taking backups even when using an automated disaster recovery strategy.

### Using BBR Backup and Restore versus Recreating a Failed PCF Deployment in Active-Active

| Disaster Recovery             |                                                                                                                                                                 |                                                                                                                                                                                                                           |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                               | Restore the PCF Data                                                                                                                                            | Recreate the PCF Data                                                                                                                                                                                                     |
| Preconditions                 | IaaS prepared for PCF install                                                                                                                                   | IaaS prepared for PCF install                                                                                                                                                                                             |

| RTO (Recovery Time Objective) |                                                                                                                                                                 |                                                                                                                                                                                                                           |
|                               |                                                                                                                                                                 |                                                                                                                                                                                                                           |

|                                       |                         |                                                                          |
|---------------------------------------|-------------------------|--------------------------------------------------------------------------|
| <b>Platform</b>                       | Time to recreate PCF    | Time to recreate PCF                                                     |
| <b>Apps</b>                           | Time to restore         | Time until orgs/spaces/etc have been recreated + apps have been repushed |
| <b>RPO (Recovery Point Objective)</b> |                         |                                                                          |
| <b>Platform</b>                       | Time of the last backup | Current time                                                             |
| <b>Apps</b>                           | Time of the last backup | Current time                                                             |

## Active-Passive

Instead of having a true active-active deployment across all layers, some Pivotal customers prefer to install a PCF or PAS deployment on a backup site. The backup site resides on-premises, in a co-location facility, or the public cloud. The backup site includes an operational deployment, with only the most critical apps ready to accept traffic should a failure occur in the primary data center. Disaster recovery in this scenario involves the following:

1. Switching traffic to the passive PCF, making it active.
2. Recovering the formerly-active PCF. Operators can choose to do this through automation, if that option is available, or by using BBR and the restore process.

The RTO and RPO for recreating the active PCF are the same as outlined in the table above.

## Reducing RTO

Both the restore and recreate data disaster recovery options require standing up a new PCF, which can take hours. If you require shorter RTO, several options involving a pre-created standby hardware and PCF are available:

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Active-cold</b>             | Public cloud environment ready for PCF installation, no PCF installed. This saves both IaaS costs and PCF instance costs. For on-prem installations, this requires hardware on standby, ready to install on, which may not be a realistic option.                                                                                                                                                                                                                                                                                                                          |
| <b>Active-warm</b>             | PCF installed on standby hardware and kept up to date, VMs scaled down to zero (spin them up each time there is a platform update), no apps installed, no orgs or spaces defined.                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Active-inflate platform</b> | Bare minimum PCF install, either with no applications, or a small number of each app in a stopped state. On recovery, push a small number of apps or start current apps, while simultaneously triggering automation to scale the platform to the primary node size, or a smaller version if large percentages of loss are acceptable. This mode allows you to start sending some traffic immediately, while not paying for a full non-primary platform. This method requires data seeded, but it is usually acceptable to complete data sync while platform is scaling up. |
| <b>Active-inflate apps</b>     | Non-primary deployment scaled to the primary node size, or smaller version if large percentages of loss are acceptable, with a small number of Diego cells (VMs). On failover, scale Diego cells up to primary node counts. This mode allows you to start sending most traffic immediately, while not paying for all the AIs of a fully fledged node. This method requires data to be there very quickly after failure. It does not require real-time sync, but near-real time.                                                                                            |

There is a tradeoff between cost and RTO: the less the replacement PCF needs to be deployed and scaled, the faster the restore.

## Automating Backups

BBR generates the backup artifacts required for PCF, but does not handle scheduling, artifact management, or encryption. The BBR team has created a [starter Concourse pipeline](#) to automate backups with BBR.

Also, Stark & Wayne's Shield can be used as a front end management tool using the BBR plugin.

## Validating Backups

To ensure that backup artifacts are valid, the BBR tool creates checksums of the generated backup artifacts, and ensures that the checksums match the

artifacts on the jumpbox.

However, the only way to be sure that the backup artifact can be used to successfully recreate PCF is to test it in the restore process. This is a cumbersome, dangerous process so should be done with care. For instructions, see [Step 11: \(Optional\) Validate Your Backup](#) of the *Backing Up Pivotal Cloud Foundry with BBR*.

## Backing Up Pivotal Cloud Foundry with BBR

Page last updated:

This topic describes the procedure for backing up your critical backend Pivotal Cloud Foundry (PCF) components with BOSH Backup and Restore (BBR), a command-line tool for backing up and restoring BOSH deployments. To restore your backup, see the [Restoring Pivotal Cloud Foundry from Backup with BBR](#) topic.

To view the BBR release notes, see the [Cloud Foundry documentation](#).

During the backup, BBR stops the Cloud Controller API and the Cloud Controller workers to create a consistent backup. Only the API functionality, like pushing applications or using the Cloud Foundry Command Line Interface (cf CLI) are affected. The deployed applications do not experience downtime.

### warning

- **Security:** Backup artifacts can contain secrets. Secure backup artifacts by using encryption or other means.
- **Compatibility:** A BBR backup can only be restored to environments matching its source environment. To ensure that a restore environment is compatible with a backup see [Compatibility of Restore](#).
- **Failed Restore:** Restore is a destructive operation. BBR is designed to restore PCF after a disaster. If a restore fails, the environment might be left in an unusable state and require re-provisioning. For more information, see [Restoring Pivotal Cloud Foundry from Backup with BBR](#).
- **Service Data:** BBR does not back up any service data.
- **API Outage:** The Cloud Controller API does not send or receive calls during PCF restoration.

## Recommendations

Pivotal recommends the following:

- Follow the full procedure documented in this topic when creating a backup. This ensures that you always have a consistent backup of Ops Manager and PAS to restore from.
- Back up frequently, especially before making any changes to your PCF deployment, such as the configuration of any tiles in Ops Manager.

## Supported Components

BBR is a binary that can back up and restore BOSH deployments and BOSH Directors. BBR requires that the backup targets supply scripts that implement the backup and restore functions. BBR can communicate securely with external blobstores and databases, using TLS, if these are configured accordingly.

BBR can back up the following components:

- [Pivotal Application Service \(PAS\)](#)
- [BOSH Director](#)

### PAS

In PCF v2.2, BBR can back up and restore PAS configured with the following:

- An internal MySQL database or a supported external database. For a list of supported external databases, see the [Supported External Databases](#) section of *Configuring Cloud Foundry for BOSH Backup and Restore* in the Cloud Foundry documentation.
- An internal WebDAV/NFS blobstore, an external Amazon S3 or S3-compatible blobstore, or an external Azure blobstore.

 **Note:** In PAS v2.2, BBR supports backing up and restoring versioned and unversioned S3 or S3-compatible blobstores by default. To back up and restore Azure blobstores with BBR, you must install Blobstore Addon. For more information, see [Enabling External Blobstore Backups](#).

For guidance about backing up unsupported databases and blobstores, see [Unsupported External Blobstores and Databases in PAS](#) below.

### BOSH Director

The BOSH Director must have an internal PostgreSQL database and an internal blobstore to be backed up and restored with BBR. As part of backing up the BOSH Director, BBR backs up the BOSH UAA database and the CredHub database.

 **Note:** BBR support for backing up and restoring external databases and blobstores varies across PCF versions. For more information, see [External Storage Support Across PCF Versions](#) below.

## External Storage Support Across PCF Versions

The following table shows what types of external databases and blobstores you can back up and restore with BBR.

| Deployment Type | Ops Manager Version                        |        |     |     |
|-----------------|--------------------------------------------|--------|-----|-----|
|                 | PAS with External Database                 | Yes    | Yes | Yes |
|                 | BOSH Director with External Database       | No     | Yes | Yes |
|                 | PAS with Amazon S3 Blobstore*              | Yes    | Yes | Yes |
|                 | BOSH Director with Amazon S3 Blobstore*    | No     | No  | No  |
|                 | PAS with S3-Compatible Blobstore           | Yes    | Yes | Yes |
|                 | BOSH Director with S3-Compatible Blobstore | No     | No  | No  |
|                 | PAS with Azure Blobstore                   | Add-on | Yes | Yes |
|                 | PAS with GCS Blobstore                     | No     | No  | No  |
|                 | BOSH Director with GCS Blobstore           | No     | No  | No  |

\* Any S3 clone that supports the versioning API.

## Unsupported External Blobstores and Databases in PAS

If you configured an unsupported external blobstore or an unsupported external database in PAS, see the following guidelines to perform a backup successfully:

| Scenario                                                                                           | Action                                                                                                                                                                          |
|----------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| You configured a supported database and an unsupported external blobstore in PAS.                  | Follow the PCF backup process and copy the external blobstore by using the IaaS-specific tool.                                                                                  |
| You configured an unsupported external database and a supported blobstore in PAS.                  | Follow the PCF backup process and copy the external database by using the IaaS-specific tool.                                                                                   |
| You configured both an unsupported external database and an unsupported external blobstore in PAS. | Follow the PCF backup process but skip the <a href="#">Back Up Your PAS Deployment</a> section below. Copy the external database and blobstore by using the IaaS-specific tool. |

 **warning:** You might encounter inconsistencies between the blobstore and database. If apps do not appear during a restore, re-push those apps.

## Backing Up Services

 **warning:** BBR does not currently back up any service data.

Keep in mind the following when backing up services:

- BBR backs up and restores the service bindings, but not the service data.
- You can redeploy on-demand service instances manually during restore, but the data in the instance is not backed up.
- BBR does not back up managed services or their data.
- You can back up and restore brokered services with the procedures documented in this topic and in the [Restoring Pivotal Cloud Foundry from Backup with BBR](#) topic.

## Backup Workflow

To install BBR, you download the `bbr` executable and copy it to a jumpbox. Once installed on your jumpbox, you can run BBR commands, specifying the name of the BOSH deployment.

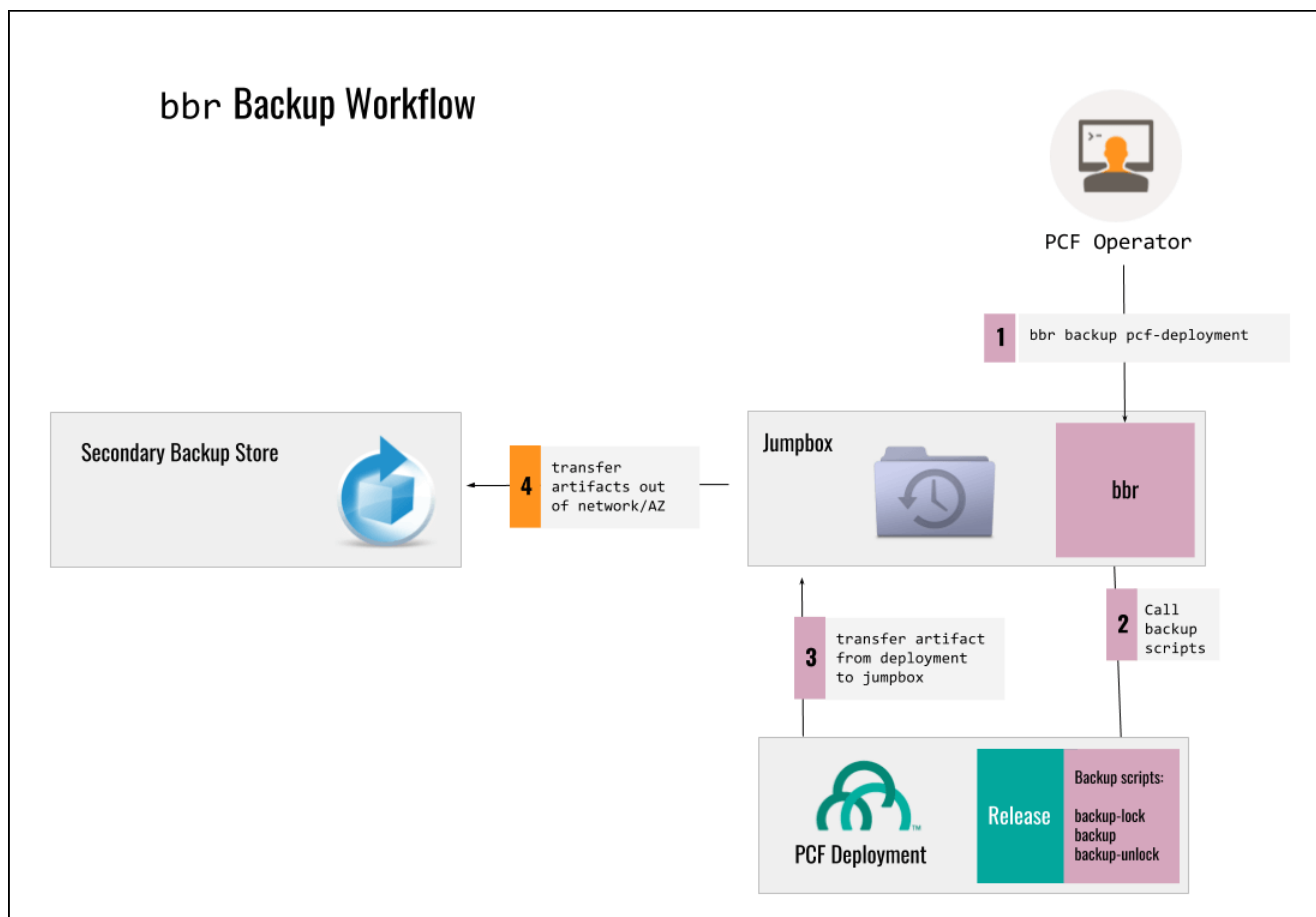

BBR examines the jobs in the BOSH deployment, and triggers the scripts in the following stages:

1. **Pre-backup lock:** The pre-backup lock scripts locks the job so backups are consistent across the cluster.
2. **Backup:** The backup script backs up the release.
3. **Post-backup unlock:** The post-backup unlock script unlocks the job after the backup is complete.

Scripts in the same stage are all triggered together. For instance, BBR triggers all pre-backup lock scripts before any backup scripts. Scripts within a stage can be triggered in any order.

The backup artifacts are drained to the jumpbox, where the operator can transfer them to storage and use them to restore PCF.

The following diagram shows a sample backup flow.

## Preparing to Create Your Backup

### Step 1: Set Up Your Jumpbox

You must have a jumpbox before you can install BBR to the jumpbox. A jumpbox is a separate, hardened server on your network that provides a controlled means of access to the VMs other computers on your network. Pivotal recommends using the Ops Manager VM as your jumpbox.

Pivotal recommends using the Ops Manager VM as your jumpbox. If you use the Ops Manager VM as your jumpbox, the path to the root Certificate Authority (CA) certificate is:

```
/var/tempest/workspaces/default/root_ca_certificate
```

You must have this path to run BBR commands.

Prepare your jumpbox for BBR by following the steps in [Setting Up Your Jumpbox for BBR](#).

 **Note:** Pivotal recommends that you regularly update the BBR binary on your jumpbox to the latest version. See [Transfer BBR Binary to Your Jumpbox](#) in *Setting Up Your Jumpbox for BBR* for more information. See the [jumpbox-deployment](#)  GitHub repository for an example jumpbox deployment.

## Step 2: Record the Cloud Controller Database Encryption Credentials

Perform the following steps to retrieve the Cloud Controller database encryption credentials from the PAS tile:

1. Navigate to Ops Manager in a browser and log in to the Ops Manager Installation Dashboard.
2. Select PAS **Credentials** and locate the Cloud Controller section.
3. Record the **Db Encryption Credentials**. You must provide these credentials when you contact [Pivotal Support](#)  for help restoring your installation.

|                  |                           |                                    |
|------------------|---------------------------|------------------------------------|
| Cloud Controller | VM Credentials            | <a href="#">Link to Credential</a> |
|                  | Db Encryption Credentials | <a href="#">Link to Credential</a> |
|                  | Encrypt Key               | <a href="#">Link to Credential</a> |
|                  | Locket Client Cert        | <a href="#">Link to Credential</a> |

## Step 3: Retrieve BOSH Director Credentials

To use BBR, you must retrieve and record the following credentials:

- Bosh Director Credentials
- Bbr Ssh Credentials
- Uaa Bbr Client Credentials

There are two ways to retrieve BOSH Director credentials:

- Ops Manager Installation Dashboard
- Ops Manager API

### Option 1: Ops Manager Installation Dashboard

To retrieve your BOSH Director credentials using the Ops Manager Installation Dashboard, perform the following steps:

1. Navigate to the Ops Manager Installation Dashboard.
2. Click the BOSH Director tile.
3. Click the **Credentials** tab.

| BOSH Director                                                |                              |                                    |
|--------------------------------------------------------------|------------------------------|------------------------------------|
| <div>Settings</div> <div>Status</div> <div>Credentials</div> |                              |                                    |
| JOB                                                          | NAME                         | CREDENTIALS                        |
| BOSH Director                                                | Vm Credentials               | <a href="#">Link to Credential</a> |
|                                                              | Agent Credentials            | <a href="#">Link to Credential</a> |
|                                                              | Registry Credentials         | <a href="#">Link to Credential</a> |
|                                                              | Director Credentials         | <a href="#">Link to Credential</a> |
|                                                              | Postgres Credentials         | <a href="#">Link to Credential</a> |
|                                                              | Blobstore Credentials        | <a href="#">Link to Credential</a> |
|                                                              | Health Monitor Credentials   | <a href="#">Link to Credential</a> |
|                                                              | Uaa Admin User Credentials   | <a href="#">Link to Credential</a> |
|                                                              | Uaa Login Client Credentials | <a href="#">Link to Credential</a> |
|                                                              | Uaa Jwt Key                  | <a href="#">Link to Credential</a> |
|                                                              | Bbr Ssh Credentials          | <a href="#">Link to Credential</a> |
|                                                              | Uaa Bbr Client Credentials   | <a href="#">Link to Credential</a> |
|                                                              | Bosh Commandline Credentials | <a href="#">Link to Credential</a> |
|                                                              | Blobstore Certificate        | <a href="#">Link to Credential</a> |

#### 4. Locate **Director Credentials**.

- Click **Link to Credentials** next to it.
- Verify the value of the `identity` field. It should be `director`.
- Copy and record the value of the `password` field.

#### 5. Locate **Bbr Ssh Credentials**.

- Click **Link to Credentials** next to it.
- Copy the value of the `private_key_pem` field.
- Run the following command to reformat the copied value, and save it in the current directory to a file named `PRIVATE-KEY-FILE`:

```
printf -- "YOUR-PRIVATE-KEY" > PRIVATE-KEY-FILE
```

Where:

- `YOUR-PRIVATE-KEY` is the text of your private key.
- `PRIVATE-KEY-FILE` is the path to the private key file you are creating.

For example:

```
$ printf -- "-----BEGIN RSA PRIVATE KEY----- MIIKeycontents -----END RSA PRIVATE KEY-----" > bbr_key.pem
```

#### 6. Locate the **Uaa Bbr Client Credentials**

- Click **Link to Credentials** next to it.

- b. Verify the value of the `identity` field. It should be `bbr_client`.
- c. Record the value of the `password` field.

## Option 2: Ops Manager API

To retrieve BOSH Director credentials using the Ops Manager API, perform the following steps:

1. Obtain your UAA access token. For more information, see [Access the API](#).
2. Retrieve the **Director Credentials** by performing the following steps:
  - a. Run the following command:

```
curl "https://OPS-MAN-FQDN/api/v0/deployed/director/credentials/director_credentials" \
-X GET \
-H "Authorization: Bearer UAA-ACCESS-TOKEN"
```

Where:

- `OPS-MAN-FQDN` is the fully-qualified domain name (FQDN) for your Ops Manager deployment.
- `UAA-ACCESS-TOKEN` is your UAA access token.

- b. Verify the value of the `identity` field. It should be `director`.
- c. Record the value of the `password` field.

3. Retrieve the **Bbr Ssh Credentials** by performing the following steps:

- a. Run the following command:

```
curl "https://OPS-MAN-FQDN/api/v0/deployed/director/credentials/bbr_ssh_credentials" \
-X GET \
-H "Authorization: Bearer UAA-ACCESS-TOKEN"
```

Where:

- `OPS-MAN-FQDN` is the fully-qualified domain name (FQDN) for your Ops Manager deployment.
- `UAA-ACCESS-TOKEN` is your UAA access token.

- b. Copy the value of the `private_key_pem` field.
- c. Run the following command to reformat the copied value, and save it in the current directory to a file named `PRIVATE-KEY-FILE`:

```
printf -- "YOUR-PRIVATE-KEY" > PRIVATE-KEY-FILE
```

Where:

- `YOUR-PRIVATE-KEY` is the text of your private key.
- `PRIVATE-KEY-FILE` is the path to the private key file you are creating.

For example:

```
$ printf -- "-----BEGIN RSA PRIVATE KEY----- MIIEkeycontents -----END RSA PRIVATE KEY-----" > bbr_key.pem
```

4. Retrieve the **Uaa Bbr Client Credentials** by performing the following steps:

- a. Run the following command:

```
curl "https://OPS-MAN-FQDN/api/v0/deployed/director/credentials/uaa_bbr_client_credentials" \
-X GET \
-H "Authorization: Bearer UAA-ACCESS-TOKEN"
```

Where:

- `OPS-MAN-FQDN` is the fully-qualified domain name (FQDN) for your Ops Manager deployment.
- `UAA-ACCESS-TOKEN` is your UAA access token.

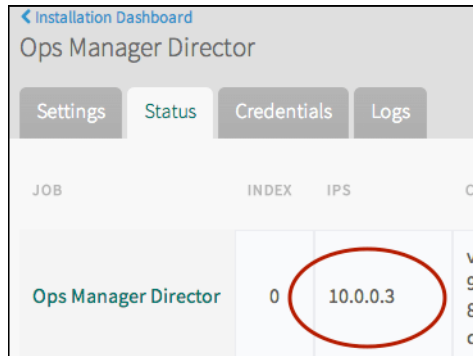

- b. Verify the value of the `identity` field. It should be `bbr_client`.
- c. Record the value of the `password` field.

For more information about using the Ops Manager API, see the [Using the Ops Manager API](#) topic.

## Step 4: Retrieve BOSH Director Address

Perform the following steps to retrieve the IP address of your BOSH Director from the BOSH Director tile:

1. If you are not using the Ops Manager VM as your jumpbox, install the latest [BOSH CLI](#) on your jumpbox.
2. From the Installation Dashboard in Ops Manager, select **BOSH Director** > **Status** and record the IP address listed for the Director. You access the

| JOB                  | INDEX | IPS      | CI                |
|----------------------|-------|----------|-------------------|
| Ops Manager Director | 0     | 10.0.0.3 | vr<br>9<br>8<br>d |

BOSH Director using this IP address.

3. From the command line, log into the BOSH Director, using the IP address that you recorded above, by running the following command:

```
bosh -e DIRECTOR-IP \
--ca-cert PATH-TO-BOSH-SERVER-CERTIFICATE log-in
```

Where:

- `DIRECTOR-IP` is the BOSH Director IP address recorded above.
- `PATH-TO-BOSH-SERVER-CERTIFICATE` is the path to the root Certificate Authority (CA) certificate as outlined in [Step 1: Set Up your Jumpbox](#), above.

4. When prompted for **Email ()**, specify `director`.
5. When prompted for **Password ()**, enter the **Director Credentials** that you obtained in [Retrieve BOSH Director Credentials](#).  
For example:

```
$ bosh -e 10.0.0.3 \
--ca-cert /var/tempest/workspaces/default/root_ca_certificate log-in
Email (): director
Password (): *****
Successfully authenticated with UAA
Succeeded
```

## Step 5: Check Your BOSH Director

Perform the following steps to confirm that your BOSH Director is reachable and can be backed up.

### Connect to Your Jumpbox

You can establish a connection to your jumpbox in one of the following ways.

- [Connect with SSH](#)
- [Connect with BOSH\\_ALL\\_PROXY](#)

**Note:** These procedures require you have a jumpbox configured for SSH access. If you do not have a jumpbox, see [Enabling SSH Access](#) and [Tunneling](#) in the BOSH documentation.

For general information about the jumpbox, see [Setting Up Your Jumpbox for BBR](#).

### Connect with SSH

There are two options available to you to connect to your jumpbox with SSH:

- Ops Manager VM.
  - SSH through the command line.
1. To connect to your jumpbox through an Ops Manager VM, perform the following steps:
    - a. Log in to the Ops Manager VM:
    - b. If you are using the Ops Manager VM as your jumpbox, see the [Log in to the Ops Manager VM with SSH](#) section of *Advanced Troubleshooting with the BOSH CLI* for information about how to use SSH to connect to the Ops Manager VM.
  2. To connect to your jumpbox through the command line, perform the following steps:
    - a. Run the following command to SSH into your jumpbox:

```
ssh -i LOCAL-PATH-TO-JUMPBOX-PRIVATE-KEY JUMPBOX-USER@JUMPBOX-ADDRESS
```

Where:

- `LOCAL-PATH-TO-JUMPBOX-PRIVATE-KEY` is the local path to your private key file for the jumpbox host.
- `JUMPBOX-USER` is your jumpbox username.
- `JUMPBOX-ADDRESS` is the IP address of your jumpbox.

 **Note:** If you connect to your jumpbox with SSH, you must run the BBR commands in the following sections from within your jumpbox.

## Connect with BOSH\_ALL\_PROXY

Set and use `BOSH_ALL_PROXY`. Using `BOSH_ALL_PROXY` opens an SSH tunnel with SOCKS5 to the jumpbox. This tunnel enables you to forward requests to the BOSH Director through the jumpbox from your local machine.

Use one of the following methods to create the tunnel:

- **Tunnel created by BOSH CLI:** To provide the BOSH CLI with the SSH credentials it needs to create the tunnel, run the following command:

```
export BOSH_ALL_PROXY=ssh+socks5://JUMPBOX@JUMPBOX-IP:SOCKS-PORT?private_key=JUMPBOX-KEY-FILE
```

Where:

- `JUMPBOX` is the name of your jumpbox.
  - `JUMPBOX-IP` is the IP address of the jumpbox.
  - `SOCKS-PORT` is the local SOCKS port.
  - `JUMPBOX-KEY-FILE` is the local SSH private key for accessing the jumpbox.
- **Tunnel established separately:**

1. To establish the tunnel and make it available on a local port, run the following command:

```
ssh -4 -D SOCKS-PORT -fNC JUMPBOX@JUMPBOX-IP -i JUMPBOX-KEY-FILE
```

Where:

- `SOCKS-PORT` is the local SOCKS port.
  - `JUMPBOX` is the name of your jumpbox.
  - `JUMPBOX-IP` is the IP address of the jumpbox.
  - `JUMPBOX-KEY-FILE` is the local SSH private key for accessing the jumpbox.
2. To provide the BOSH CLI with access to the tunnel through use of the `BOSH_ALL_PROXY` environment variable, run the following command:

```
export BOSH_ALL_PROXY=socks5://localhost:SOCKS-PORT
```

 **Note:** Ensure the SOCKS port is not already in use by a different tunnel/process.

 **Note:** Using `BOSH_ALL_PROXY` can result in longer backup and restore times due to network performance degradation. Because all operations must pass through the proxy, moving backup artifacts can be significantly slower.

## Check Your BOSH Director

1. Run the BBR `pre-backup-check` command:

```
bbr director \
--private-key-path PRIVATE-KEY-FILE \
--username bbr \
--host HOST \
pre-backup-check
```

Where:

- `PRIVATE-KEY-FILE` is the path to the private key file that you created from **Bbr Ssh Credentials** in [Step 3: Retrieve BOSH Director Credentials](#).
- `HOST` is the address of the BOSH Director. If the BOSH Director is public, `HOST` is a URL, such as `https://my-bosh.xxx.cf-app.com`. Otherwise, `HOST` is the `BOSH-DIRECTOR-IP` which you retrieved in the [Step 4: Retrieve BOSH Director Address](#) section of this topic above.

 **Note:** Use the optional `--debug` flag to enable debug logs. See the [Logging](#) section below for more information.

2. After the pre-backup check succeeds, continue to [Step 5: Confirm Backup Restore Node is Deployed](#) below.  
If the pre-backup check fails, the BOSH Director might not have the correct backup scripts, or the connection to the BOSH Director might have failed.

## Step 6: Confirm Backup Restore Node is Deployed

When BBR backs up PAS, it needs a Backup Prepare node. This procedure confirms that the Backup Prepare node is deployed.

1. In Ops Manager, open the **Pivotal Application Service** tile.
2. In the **Resource Config** pane find the **Backup Prepare Node** job and check if the **Instances** dropdown is set to `1`.

|                     |                                |                   |                                             |
|---------------------|--------------------------------|-------------------|---------------------------------------------|
| Backup Prepare Node | <input type="text" value="1"/> | Automatic: 200 GB | Automatic: t2.micro (cpu: 1, ram: 1 GB, dis |
|---------------------|--------------------------------|-------------------|---------------------------------------------|

3. If the **Instances** dropdown is not set to `1`:
  - a. Set the **Instances** dropdown to `1`.
  - b. Click **Save**.
  - c. Navigate back to the Installation Dashboard and click **Apply Changes** to redeploy.

## Step 7: Identify Your Deployment

1. Log in to your BOSH Director.
2. To identify the name of the BOSH deployment that contains PCF, run the following command:

```
bosh -e BOSH-DIRECTOR-IP --ca-cert PATH-TO-BOSH-SERVER-CERTIFICATE deployments
```

Where:

- `BOSH-DIRECTOR-IP` is the BOSH Director IP retrieved in the [Step 4: Retrieve BOSH Director Address](#) section above.
- `PATH-TO-BOSH-SERVER-CERTIFICATE` is the path to the Certificate Authority (CA) certificate for the BOSH Director.

```
$ bosh -e BOSH-DIRECTOR-IP --ca-cert PATH-TO-BOSH-SERVER-CERTIFICATE deployments
```

```
Name Release(s)
cf-example push-apps-manager-release/661.1.24
 cf-backup-and-restore/0.0.1
 binary-buildpack/1.0.11
 capi/1.28.0
 cf-autoscaling/91
 cf-mysql/35
 ...
```

In the above example, the name of the BOSH deployment that contains PCF is `cf-example`.

## Step 8: Check Your Deployment

Perform the following steps to check that your BOSH Director is reachable and has a deployment that can be backed up:

1. Run the BBR pre-backup check:

```
bbr deployment \
--target BOSH-DIRECTOR-IP \
--username BOSH-CLIENT \
--password BOSH-PASSWORD \
--deployment DEPLOYMENT-NAME \
--ca-cert PATH-TO-BOSH-SERVER-CERTIFICATE \
pre-backup-check
```

Where:

- `BOSH-DIRECTOR-IP` is the BOSH Director IP retrieved in the [Step 4: Retrieve BOSH Director Address](#) section above.
- `BOSH-CLIENT`, `BOSH-PASSWORD` are the **Uaa Bbr Client Credentials**, identity and password, that you retrieved in the [Step 3: Retrieve BOSH Director Credentials](#) section above.
- `DEPLOYMENT-NAME` is the deployment name retrieved in the [Step 6: Identify Your Deployment](#) section above.
- `PATH-TO-BOSH-SERVER-CERTIFICATE` is the path to the Certificate Authority (CA) certificate for the BOSH Director. For more information, see [Ensure BOSH Director Certificate Availability](#).

2. After the pre-backup check succeeds, continue to [Create Your Backup](#) below.

If the pre-backup check fails, the deployment you selected might not have the correct backup scripts, or the connection to the BOSH Director might have failed.

## Creating Your Backup

### Step 9: Export Installation Settings

Pivotal recommends that you back up your Ops Manager installation settings by exporting frequently.

When exporting your installation settings, keep in mind the following:

- This option is only available after you have deployed at least once.
- Always export your installation settings before following the steps in the [Deploy Ops Manager and Import Installation Settings](#) section of the *Restoring Pivotal Cloud Foundry from Backup with BBR* topic.
- Exporting your installation settings only backs up the settings you configured in Ops Manager. It does not back up your VMs or any external MySQL databases.
- Your Ops Manager settings are encrypted. Make sure you keep track of your Decryption Passphrase because this is needed to restore the Ops Manager settings.

 **Note:** When exporting installation settings for Ops Manager v1.12 and later, releases are not included in the output file. Releases are now included in the BOSH Director backup, therefore, the output file is much smaller than in previous Ops Manager versions.

There are two ways to export Ops Manager installation settings:

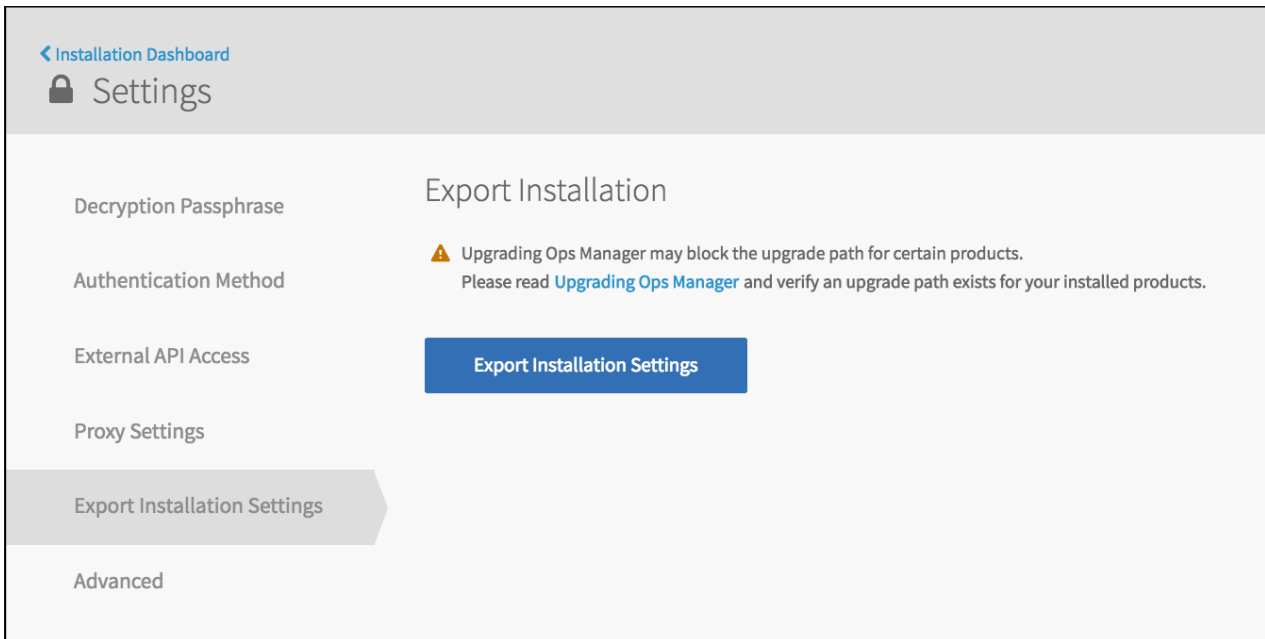

- [Use the Ops Manager UI](#)
- [Use the Ops Manager API](#)

#### Option 1: Use the Ops Manager UI

To export your installation settings using the Ops Manager UI, do the following:

1. From the **Installation Dashboard** in the Ops Manager interface, click your username at the top right navigation.
2. Select **Settings**.
3. Select **Export Installation Settings**.

## 4. Click **Export Installation Settings**.

## Option 2: Use the Ops Manager API

If you want to automate the back up process, you can use the Ops Manager API to export your installation settings.

### 1. To export your installation settings using the Ops Manager API, run the following command:

```
curl https://OPS-MAN-FQDN/api/v0/installation_asset_collection \
-H "Authorization: Bearer UAA-ACCESS-TOKEN" > installation.zip
```

Where:

- `OPS-MAN-FQDN` is the fully-qualified domain name (FQDN) for your Ops Manager deployment.
- `UAA-ACCESS-TOKEN` is your UAA access token. For more information, see [Access the API](#).

## Step 10: Back Up Your BOSH Director

### Notes:

- The BOSH Director backup can take more than 10 minutes.
  - Because the BBR `backup` command can take a long time to complete, Pivotal recommends you run it independently of the SSH session so that the process can continue running even if your connection to the jumpbox fails.
- Use `nohup`, a `screen`, or a `tmux` session.

### 1. Run the BBR `backup` command to back up your BOSH Director:

```
bbr director \
--private-key-path PRIVATE-KEY-FILE \
--username bbr \
--host HOST \
backup
```

Where:

- `PRIVATE-KEY-FILE` is the path to the private key file that you created from **Bbr Ssh Credentials** in [Step 3: Retrieve BOSH Director Credentials](#).
- `HOST` is the address of the BOSH Director:
  - If the BOSH Director is public, `HOST` is a URL, such as `https://my-bosh.xxx.cf-app.com`.
  - If the BOSH Director is not public, `HOST` is the `BOSH-DIRECTOR-IP` retrieved in the [Step 4: Retrieve BOSH Director Address](#) section above.

 **Note:** Use the optional `--debug` flag to enable debug logs. See [Logging](#) below for more information.

If your backup terminates early or fails you need to perform a clean-up.

1. To clean up, run the following `backup-cleanup` command:

```
bbr director \
--private-key-path PRIVATE-KEY-FILE \
--username bbr \
--host HOST \
backup-cleanup
```

Where:

- `PRIVATE-KEY-FILE` is the path to the private key file that you created from **Bbr Ssh Credentials** in [Step 3: Retrieve BOSH Director Credentials](#).
- `HOST` is the address of the BOSH Director:
  - If the BOSH Director is public, `HOST` is a URL, such as `https://my-bosh.xxx.cf-app.com`.
  - If the BOSH Director is not public, `HOST` is the `BOSH-DIRECTOR-IP` retrieved in the [Step 4: Retrieve BOSH Director Address](#) section above.

## Step 11: Back Up Your PAS Deployment

### Notes:

- Backing up PAS can take more than 5 minutes, and can take considerably longer with larger blobstores or slow network connections. The backup also incurs Cloud Controller downtime during which users are unable to push, scale, or delete apps. Your apps are not affected.
- Because the BBR `backup` command can take a long time to complete, Pivotal recommends you run it independently of the SSH session, so that the process can continue running even if your connection to the jumpbox fails. The command above uses `nohup` but you could also run the command in a `screen` or `tmux` session.

1. (Optional) If you are not using an internal blobstore or a versioned S3-compatible external blobstore, create a copy of the blobstore with your IaaS specific tool. Your blobstore backup might be slightly inconsistent with your PAS backup depending on the duration of time between performing the backups.
2. Run the BBR `backup` command to back up your PAS deployment:

```
bbr deployment \
--target BOSH-DIRECTOR-IP \
--username BOSH-CLIENT \
--password BOSH-PASSWORD \
--deployment DEPLOYMENT-NAME \
--ca-cert PATH-TO-BOSH-SERVER-CERTIFICATE \
backup
```

Where:

- `BOSH-DIRECTOR-IP` is the BOSH Director IP retrieved in the [Step 4: Retrieve BOSH Director Address](#) section above.
  - `BOSH-CLIENT`, `BOSH-PASSWORD` are the **Uaa Bbr Client Credentials**, identity and password, that you retrieved in the [Step 3: Retrieve BOSH Director Credentials](#) section above.
  - `DEPLOYMENT-NAME` is the deployment name retrieved in the [Step 6: Identify Your Deployment](#) section above.
  - `PATH-TO-BOSH-SERVER-CERTIFICATE` is the path to the Certificate Authority (CA) certificate for the BOSH Director.
  - Use the optional `--debug` flag to enable debug logs. For more information, see [Logging](#) below.
  - Use the optional `--with-manifest` flag to ensure that BBR downloads your current deployment manifest when backing up. These manifests are included in the Ops Manager export, but are useful for reference.
3. After the command successfully completes, continue to [Step 11: Transfer Backup Artifacts](#).  
If the command fails, perform the following steps:
    - a. Run the BBR `backup-cleanup` command:

```
bbr deployment \
--target BOSH-DIRECTOR-IP \
--username BOSH-CLIENT \
--password BOSH-PASSWORD \
--deployment DEPLOYMENT-NAME \
--ca-cert PATH-TO-BOSH-SERVER-CERTIFICATE \
backup-cleanup
```

Where:

- `BOSH-DIRECTOR-IP` is the BOSH Director IP retrieved in the [Step 4: Retrieve BOSH Director Address](#) section above.
- `BOSH-CLIENT`, `BOSH-PASSWORD` are the **Uaa Bbr Client Credentials**, identity and password, that you retrieved in the [Step 3: Retrieve BOSH Director Credentials](#) section above.
- `DEPLOYMENT-NAME` is the deployment name retrieved in the [Step 6: Identify Your Deployment](#) section above.
- `PATH-TO-BOSH-SERVER-CERTIFICATE` is the path to the Certificate Authority (CA) certificate for the BOSH Director.
- Use the optional `--debug` flag to enable debug logs. For more information, see [Logging](#) below.
- Use the optional `--with-manifest` flag to ensure that BBR downloads your current deployment manifest when backing up. These manifests are included in the Ops Manager export, but are useful for reference.

b. Run the BBR `backup` command again after checking the following:

- All the parameters in the command are set.
- The BOSH Director credentials are valid.
- The specified deployment exists.

## After Taking Your Backup

### Step 12: Transfer Backup Artifacts

After creating your backup successfully, perform the following steps:

1. Move the backup artifacts off the jumpbox to your preferred storage space. The backup created by BBR consists of a directory with the backup artifacts and metadata files. Pivotal recommends compressing and encrypting the files.
2. Make redundant copies of your backup artifacts and store them in multiple locations to minimize the risk of losing backups in the event of a disaster.
3. Attempt to restore every backup to validate the artifacts. Perform the procedures in the next step, [Step 12: Validate Your Backup](#).

 **Note:** Backup artifacts might contain data covered by European Union regulations. For more information, see [European Union's General Data Protection Regulation \(GDPR\)](#) below.

### Step 13: (Optional) Validate Your Backup

After backing up PCF, consider validating your backup by restoring it and checking the applications. BBR is designed for disaster recovery and BBR backups are only compatible with environments matching their source environment's configuration.

#### warning:

- **The VMs and disks from the backed-up BOSH Director must not be visible to the new BOSH Director** when validating your backup. As a result, Pivotal recommends that you deploy the new BOSH Director to a different IaaS network and account than the VMs and disks of the backed-up BOSH Director.
- **Data services outside of PCF might produce unexpected side effects during restoration.** Restored apps and services might attempt to connect to data services when you restore to a new environment. For example, consider an app that processes mail queues and connects to an external database. When you validate your backup in a test environment, the app might start processing the queue, and this work might be lost.

#### Validate Your Backup in a Second Environment

To spin up a second environment and test the backup, perform the following steps:

1. Export your Ops Manager installation by performing the steps in the [Step 8: Export Installation Settings](#) section above.
2. Create a new Ops Manager VM in a different network to the original. Ensure that the Ops Manager VM has enough persistent disk to accommodate the files exported in the previous step. Consult the topic specific to your IaaS:
  - [Deploying BOSH and Ops Manager to AWS](#)
  - [Configuring AWS for PCF](#)
  - [Deploying Ops Manager on GCP Manually](#)
  - [Provisioning the OpenStack Infrastructure](#)
  - [Deploying Operations Manager to vSphere](#)
3. Ensure that the restore environment is compatible with the backup. For more information, see [Compatibility of Restore](#).
4. Follow the instructions in the [Restoring Pivotal Cloud Foundry from Backup with BBR](#) topic.

## Validate Your PAS Backup Only

For a sandbox or other non-production environment, you can optionally perform an *in-place* restore of PAS only. In this case, you restore the PAS backup to the same PCF environment that the backup was created from. Follow the procedures in [Restoring PCF from Backup with BBR](#).

## Logging

BBR outputs logs to stdout. By default, BBR logs:

- The backup and restore scripts that it finds
- When it starts or finishes a stage, such as pre-backup scripts or backup scripts
- When the process is complete
- When any error occurs

If you require additional logging, use the optional `--debug` flag to print the following information:

- Logs about the API requests made to the BOSH server
- All commands executed on remote instances
- All commands executed on local environment
- Standard in and standard out streams for the backup and restore scripts when they are executed

## Cancel a Backup

If you need to cancel a backup, perform the following steps:

1. Enter `CTRL-C` to terminate the BBR process, then enter `yes` to confirm.
2. Run the BBR `backup-cleanup` command.

- For a canceled director backup, run the following:

```
bbr director \
--private-key-path PRIVATE-KEY-FILE \
--username bbr \
--host HOST \
backup-cleanup
```

Where:

- `PRIVATE-KEY-FILE` is the path to the private key file that you created from **Bbr Ssh Credentials** in [Step 3: Retrieve BOSH Director Credentials](#).
  - `HOST` is the address of the BOSH Director:
    - If the BOSH Director is public, `HOST` is a URL, such as `https://my-bosh.xxx.cf-app.com`.
    - If the BOSH Director is not public, `HOST` is the `BOSH-DIRECTOR-IP` retrieved in the [Step 4: Retrieve BOSH Director Address](#) section above.
- For a canceled deployment backup, run the following:

```
bbr deployment \
--target BOSH-DIRECTOR-IP \
--username BOSH-CLIENT \
--password BOSH-PASSWORD \
--deployment DEPLOYMENT-NAME \
--ca-cert PATH-TO-BOSH-SERVER-CERTIFICATE \
backup-cleanup
```

Where:

- `BOSH-DIRECTOR-IP` is the BOSH Director IP retrieved in the [Step 4: Retrieve BOSH Director Address](#) section above.
- `BOSH-CLIENT`, `BOSH-PASSWORD` are the **Uaa Bbr Client Credentials**, identity and password, that you retrieved in the [Step 3: Retrieve BOSH Director Credentials](#) section above.
- `DEPLOYMENT-NAME` is the deployment name retrieved in the [Step 6: Identify Your Deployment](#) section above.
- `PATH-TO-BOSH-SERVER-CERTIFICATE` is the path to the Certificate Authority (CA) certificate for the BOSH Director.
- Use the optional `--debug` flag to enable debug logs. For more information, see [Logging](#) above.
- Use the optional `--with-manifest` flag to ensure that BBR downloads your current deployment manifest when backing up. These manifests are included in the Ops Manager export, but are useful for reference.

## European Union’s General Data Protection Regulation (GDPR)

Backup artifacts might contain personal and other data covered by the European Union’s *General Data Protection Regulation (GDPR)*. For example, a PAS backup could contain user email addresses. As such, handle backup artifacts in accordance with organizational policies and applicable laws as they pertain to security, confidentiality, and privacy.

## Enabling External Blobstore Backups

Page last updated:

This topic provides instructions for enabling external blobstore backups in your Pivotal Application Service (PAS) tile.

BOSH Backup and Restore (BBR) supports the following:

- Versioned S3 or S3-Compatible Blobstores
- Unversioned S3 or S3-Compatible Blobstores
- Azure Blobstores

For more information, see [Backup and Restore with External Blobstores](#).

**Note:** To enable external blobstore backups for PAS, the **Backup Prepare Node** must be enabled. See [Enable Backup Prepare Node](#) in *Backing Up Pivotal Cloud Foundry with BBR*.

**Note:** The instructions below require the BOSH Command Line Interface (CLI) v2+. For more information, see [Install](#) in the BOSH documentation.

## External Blobstore Support

External blobstore backup support varies based on which version of Ops Manager you are running and what type of blobstore you are backing up.

In some cases, external blobstore support is included in the version of Ops Manager you are using. In other cases, installing Blobstore Add-On is required.

Refer to the table below to determine if external blobstore support is included in the version of Ops Manager you are using.

| Blobstore Type | Ops Manager Version |        |        |        |          |          |
|----------------|---------------------|--------|--------|--------|----------|----------|
|                | Versioned           | Add-On | Add-On | Add-On | Included | Included |
|                | Unversioned         | Add-On | Add-On | Add-On | Add-On   | Included |
|                | Azure               | Add-On | Add-On | Add-On | Add-On   | Included |

## S3 or S3-compatible Blobstores

In PAS v2.2, BBR supports backing up and restoring versioned and unversioned S3 or S3-compatible blobstores by default. For more information about configuring an S3 or S3-compatible blobstore, see [External S3 or Ceph Filestore](#).

**Note:**

- Backup artifacts of external, S3-compatible, versioned blobstores do not contain the physical blobs. BBR requires that the original buckets still exist to be restored.
- To protect yourself from losing a bucket, see [Enable Replication on Your External Blobstore](#) in *Backup and Restore with External Blobstores* in the Cloud Foundry documentation.

## Azure Blobstores

For information about configuring an Azure blobstore for backups and installing Blobstore Add-On, see the following sections:

- [Configure an Azure Blobstore for Backups](#)
- [Install Blobstore Add-On](#)

## Configure an Azure Blobstore for Backups

To configure your Azure blobstore for backups, enable soft deletes in your Azure Storage account. For more information, see [Soft delete for Azure Storage blobs](#) in the Microsoft documentation.

To save storage space and cost, Pivotal recommends that you configure a retention policy to permanently delete objects after a period of time.

## Install Blobstore Add-On

To enable BBR to back up and restore a PAS installation that uses an Azure blobstore, you must install Blobstore Add-On.

To install Blobstore Add-On, follow the instructions below:

1. On the Ops Manager Installation Dashboard, click the PAS tile.
2. From the URL in the address bar, record the deployment name of your PAS installation. The name begins with `cf`. For example, in `https://pcf.example.com/products/cf-3247176589a379f246d1`, the deployment name is `cf-3247176589a379f246d1`.
3. Navigate to the Ops Manager Installation Dashboard and click the BOSH Director tile.
4. In the BOSH Director tile, select the **Credentials** tab.
5. Locate **Director Credentials** and click the corresponding **Link to Credentials**. Record the identity and password.
6. Select the **Status** tab. Record the IP address of your BOSH Director.
7. From the [BOSH Backup and Restore](#) page in Pivotal Network, download the latest version of the add-on.
8. To copy the release archive to your Ops Manager instance, run the following command:

```
scp -i PATH-TO-PRIVATE-KEY backup-and-restore-sdk-addon-SEMMVER.tar.gz ubuntu@YOUR-OPS-MANAGER-VM-IP:~
```

Where:

- `PATH-TO-PRIVATE-KEY` is the path to your Ops Manager private key.
- `SEMMVER` is the semantic version of the add-on that you downloaded in the previous step.
- `YOUR-OPS-MANAGER-VM-IP` is the IP address of your Ops Manager VM.

9. SSH into the Ops Manager instance by following the instructions in [SSH Into Ops Manager VM](#).
10. In the Ops Manager VM, authenticate with your BOSH Director by following the instructions in [Log in to the BOSH Director](#). Use the Director Credentials and Director IP address that you recorded in previous steps.
11. To upload the release that you downloaded from Pivotal Network, run the following command:

```
bosh -e BOSH-DIRECTOR-IP --ca-cert /var/tempest/workspaces/default/root_ca_certificate upload-release backup-and-restore-sdk-addon-SEMMVER.tar.gz
```

Where:

- `BOSH-DIRECTOR-IP` is the IP address of your BOSH Director.
- `SEMMVER` is the semantic version of the add-on that you are uploading.

12. To confirm that the release upload has succeeded, run the following command:

```
bosh -e BOSH-DIRECTOR-IP --ca-cert /var/tempest/workspaces/default/root_ca_certificate releases
```

Where `BOSH-DIRECTOR-IP` is the IP address of your BOSH Director.

You should see a `backup-and-restore-sdk-addon-SEMMVER` entry.

13. To download your current runtime configuration and save it as a file named `runtime-config.yml`, run the following command:

```
bosh -e BOSH-DIRECTOR-IP --ca-cert /var/tempest/workspaces/default/root_ca_certificate runtime-config > runtime-config.yml
```

Where `BOSH-DIRECTOR-IP` is the IP address of your BOSH Director.

If you receive an error message that references a missing runtime configuration, create an empty file and save it as `runtime-config.yml`.

14. Append the following to the `releases` section of your `runtime-config.yml` file:

```
releases:
Append the below to the list of releases:
- name: backup-and-restore-sdk-addon
 version: RELEASE-VERSION
```

Where `RELEASE-VERSION` is the release version.

15. Append the following to the `addons` section of your `runtime-config.yml` file:

```
addons:
Append the below to the list of addons:
- name: sdk-preview
 jobs:
 - name: azure-blobstore-backup-restorer
 release: backup-and-restore-sdk-addon
 properties:
 enabled: true
 containers:
 droplets:
 name: NAME-OF-DROPLETS-CONTAINER
 azure_storage_account: AZURE-STORAGE-ACCOUNT
 azure_storage_key: AZURE-STORAGE-KEY
 packages:
 name: NAME-OF-PACKAGES-CONTAINER
 azure_storage_account: AZURE-STORAGE-ACCOUNT
 azure_storage_key: AZURE-STORAGE-KEY
 buildpacks:
 name: NAME-OF-BUILDPACKS-CONTAINER
 azure_storage_account: AZURE-STORAGE-ACCOUNT
 azure_storage_key: AZURE-STORAGE-KEY
 include:
 deployments:
 - PAS-DEPLOYMENT-NAME
 jobs:
 - name: mysql-backup
 release: cf-backup-and-restore
```

Replace the placeholder text as follows:

- In the `droplets`, `packages`, and `buildpacks` section, replace the text with the values configured in Ops Manager.
- In the `include` section, replace the text with the PAS deployment name that you recorded in a previous step.

16. (Optional) To configure backup and restore for Azure Sovereign Cloud, configure the `environment` property described in the [Backup and Restore SDK Documentation](#) topic in GitHub.

For more information about Azure Sovereign Cloud, see [Microsoft National Clouds](#) in the Microsoft documentation.

17. To complete updating the runtime configuration, run the following command:

```
bosh -e BOSH-DIRECTOR-IP --ca-cert /var/tempest/workspaces/default/root_ca_certificate update-runtime-config runtime-config.yml
```

Where `BOSH-DIRECTOR-IP` is the IP address of your BOSH Director.

18. Navigate to your Ops Manager Installation Dashboard and click **Apply Changes**.

## PAS Component Availability During Backup

This topic describes the operational impact of backing up Pivotal Application Service (PAS) components with BBR. To ensure correctness of backups, each component that requires backup has its own set of scripts. The sections in this topic describe the availability of each component during backup of its database.

### Cloud Controller

The Cloud Controller is unavailable during backup. Apps and Services continue to run as normal, but you cannot perform operations that require the [Cloud Controller API](#). This includes the following:

- Pushing new apps or creating new services
- Modifying existing apps or services
- Using the clients of the Cloud Controller API, such as the following:
  - The Cloud Foundry Command Line Interface (cf CLI)
  - Apps Manager and its integrations
  - The [Java client](#) used by Spring apps

The backup process for the Cloud Controller is as follows:

| Stage                 | Description                                                                                                                                  |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| 1: Pre-backup lock    | The processes running on the <b>Cloud Controller Worker</b> , <b>Cloud Controller</b> , and <b>Clock Global</b> VMs are stopped.             |
| 2: Backup             | The BBR SDK backup script runs to backup the Cloud Controller database (CCDB), which contains state information for apps on your deployment. |
| 3: Post-backup unlock | The processes start again on the <b>Cloud Controller Worker</b> , <b>Cloud Controller</b> , and <b>Clock Global</b> VMs.                     |

### UAA

UAA remains available in read-only mode during backup. This means that you cannot perform write operations for clients, users, groups, identity providers, or zone configuration. However, you can continue performing read operations, such as generating, validating, and revoking tokens. Additionally, UAA continues to authenticate users and authorize requests for users and clients.

The read-only behavior during backup applies to all of the following ways of accessing UAA: the UAA API, the UAA CLI, cf CLI, login screens, and services such as the Single Sign-On Service tile.

The backup process for UAA is as follows:

| Stage                 | Description                                                                                               |
|-----------------------|-----------------------------------------------------------------------------------------------------------|
| 1: Pre-backup lock    | UAA enters read-only mode.                                                                                |
| 2: Backup             | The BBR SDK backup script runs to backup the UAA database, which contains Cloud Foundry user credentials. |
| 3: Post-backup unlock | UAA exits read-only mode.                                                                                 |

### Routing API

The [Routing API](#) remains available during backup. However, you cannot perform write operations using the Routing API because the routing database is locked. All read operations offered by the Routing API remain available.

The BBR SDK backup script for the Routing API backs up its database, which contains router groups, routes, and internal implementation information.

### Usage Service

The Usage Service is unavailable during backup. You cannot access the API as described in [Monitoring App, Task, and Service Instance Usage](#). Additionally, you cannot view usage and accounting reports as described in [Monitoring Instance Usage with Apps Manager](#).

The backup process for Usage Service is as follows:

 **Note:** The Usage Service runs as a set of Cloud Foundry apps in the `system` org.

| Stage                 | Description                                                                                                                                 |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| 1: Pre-backup lock    | The Usage Service apps in the <code>system</code> org stop. This lock occurs before the Cloud Controller and UAA components lock.           |
| 2: Backup             | The BBR SDK backup script runs to backup the Usage Service database.                                                                        |
| 3: Post-backup unlock | The Usage Service apps in the <code>system</code> org start again. This unlock occurs after the Cloud Controller and UAA components unlock. |

## App Autoscaler

The [App Autoscaler service](#) is unavailable during backup. You cannot access the UI or API. For any apps configured to use the App Autoscaler, the service does not scale these apps during backup.

The backup process for App Autoscaler is as follows:

 **Note:** The App Autoscaler service runs as a set of Cloud Foundry apps in the `system` org.

| Stage                 | Description                                                                                                                              |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| 1: Pre-backup lock    | The Autoscaler apps in the <code>system</code> org stop. This lock occurs before the Cloud Controller and UAA components lock.           |
| 2: Backup             | The BBR SDK backup script runs to backup the App Autoscaler database.                                                                    |
| 3: Post-backup unlock | The Autoscaler apps in the <code>system</code> org start again. This unlock occurs after the Cloud Controller and UAA components unlock. |

## NFS Volume Service

The NFS service broker backup scripts rely on the locking of the Cloud Controller to stop traffic to its service. This is because the Cloud Controller is responsible for invoking the NFS service broker.

When the Cloud Controller locks during backup, you cannot create or delete new instances or bindings of a volume service. However, apps already bound to a volume service continue to operate normally during backups.

The NFS service broker backup script performs a backup of the database used to store service instances and service bindings for the NFS service broker.

## Notification Service

The Notification Service is not available during backup with BBR due to its dependency on the Cloud Controller. Notifications cannot be sent while the Cloud Controller is unavailable.

## Network Policy Server

The Network Policy Server is unavailable during backup. While existing policies are still enforced, you cannot use the cf CLI to add or remove policies for Container Networking as documented in [Administering Container-to-Container Networking](#).

## CredHub

Runtime CredHub is unavailable during backup. If the service instance credentials for an app are stored in CredHub, the app cannot fetch those credentials during backup. In some cases, apps may not start if they cannot fetch credentials for a service instance binding.

## Restoring PCF from Backup with BBR

Page last updated:

This topic describes the procedure for restoring your critical backend Pivotal Cloud Foundry (PCF) components with BOSH Backup and Restore (BBR), a command-line tool for backing up and restoring BOSH deployments. To perform the procedures in this topic, you must have backed up PCF by following the steps in the [Backing Up Pivotal Cloud Foundry with BBR](#) topic.

To view the BBR release notes, see [BOSH Backup and Restore Release Notes](#).

The procedures described in this topic prepare your environment for PCF, deploy Ops Manager, import your installation settings, and use BBR to restore your PCF components.

**⚠ warning:** Restoring PCF with BBR is a destructive operation. If the restore fails, the new environment may be left in an unusable state and require reprovisioning. Only perform the procedures in this topic for the purpose of disaster recovery, such as recreating PCF after a storage-area network (SAN) corruption.

**⚠ warning:** When validating your backup, the VMs and disks from the backed-up BOSH Director should not be visible to the new BOSH Director. As a result, Pivotal recommends that you deploy the new BOSH Director to a different IaaS network and account than the VMs and disks of the backed up BOSH Director.

**💡 Note:** If the BOSH Director you are restoring had any deployments that were deployed manually rather than through an Ops Manager tile, you must restore them manually at the end of the process. For more information, see [\(Optional\) Step 16: Restore Non-Tile Deployments](#).

## Compatibility of Restore

This section describes the restrictions for a backup artifact to be restorable to another environment. This section is for guidance only, and Pivotal highly recommends that operators validate their backups by using the backup artifacts in a restore.

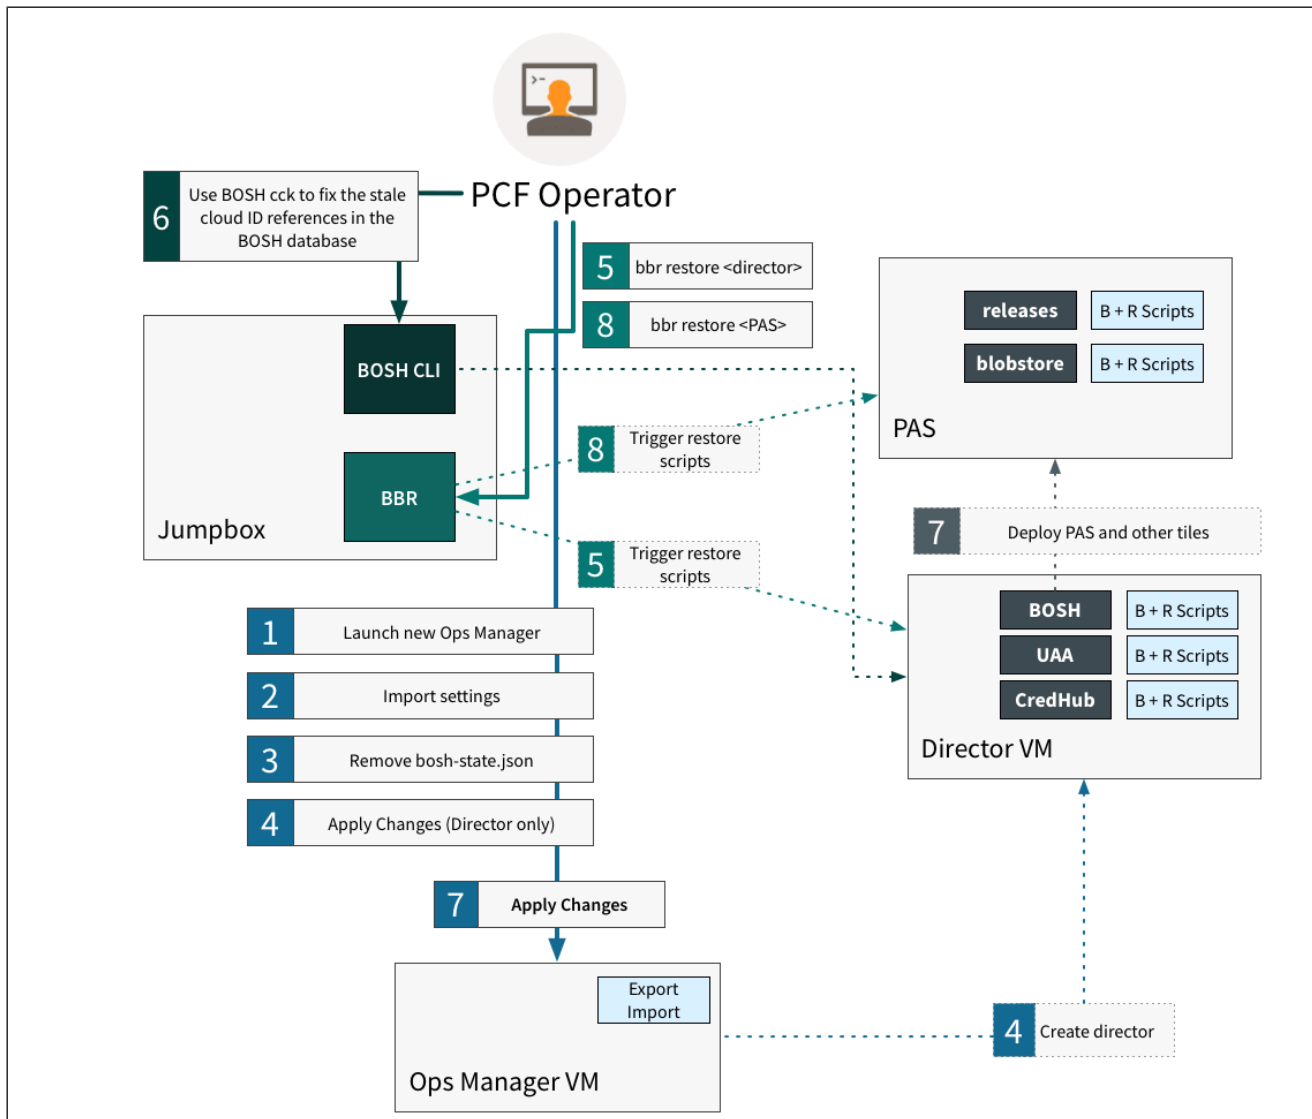

Consult the following restrictions for a backup artifact to be restorable:

- **CIDR ranges:** BBR requires the IP address ranges to be the same in the restore environment as in the backup environment.
- **Topology:** BBR requires the BOSH topology of a deployment to be the same in the restore environment as it was in the backup environment.
- **Naming of instance groups and jobs:** For any deployment that implements the backup and restore scripts, the instance groups and jobs must have the same names.
- **Number of instance groups and jobs:** For instance groups and jobs that have backup and restore scripts, there must be the same number of instances.
- **Limited validation:** BBR puts the backed up data into the corresponding instance groups and jobs in the restored environment, but can't validate the restore beyond that. For example, if the MySQL encryption key is different in the restore environment, the BBR restore might succeed although the restored MySQL database is unusable.
- **PCF version:** BBR can restore to the same version of PCF that was backed up. BBR does not support restoring to other major, minor, or patch releases.

**💡 Note:** A change in VM size or underlying hardware will not affect BBR's ability to restore data, as long as there is adequate storage space to restore the data.

## Restore Workflow

Click the diagram below to see the full-size image.

The diagram above shows the flow of the PCF restore process in a series of steps performed by the PCF operator. The following steps will be covered in more detail throughout this topic.

1. **Launch new Ops Manager:** Perform the procedures for your IaaS to deploy Ops Manager. See part one of the [Deploy Ops Manager and Import Installation Settings](#) step below for more information.
2. **Import settings:** You can import settings either with the Ops Manager UI or API. See part two of the [Deploy Ops Manager and Import Installation Settings](#) step below for more information.
3. **Remove bosh-state.json:** SSH into your Ops Manager VM and delete the `bosh-state.json` file. See the [Remove BOSH State File](#) step below for more information.
4. **Apply Changes (Director only):** Use the Ops Manager API to only deploy the BOSH Director. See the [Deploy the BOSH Director](#) step below for more information.
5. **bbr restore <director>:** Run the BBR restore command from your jumpbox to restore the BOSH Director. See the [Restore the BOSH Director](#) step below for more information.
6. **Use BOSH cck to fix the stale cloud ID references in the BOSH database:** For each deployment in the BOSH Director, you will need to run a `bosh cloud-check` command. See the [Remove Stale Cloud IDs for All Deployments](#) step below for more information.
7. **Apply Changes:** Click **Apply Changes** from the Ops Manager Installation Dashboard.
8. **bbr restore PAS:** Run the BBR restore command from your jumpbox to restore PAS. See the [Restore PAS](#) step below for more information.

## Prepare to Restore

This section provides the steps you need to perform before restoring your PCF backup with BBR.

### Step 1: (Optional) Prepare Your Environment

In an event of a disaster, you may lose not only your VMs and disks, but your IaaS resources as well, such as networks and load balancers.

If you need to recreate your IaaS resources, prepare your environment for PCF by following the instructions specific to your IaaS in [Installing Pivotal Cloud Foundry](#).

**Note:** The instructions for installing PCF on Amazon Web Services (AWS) and OpenStack combine the procedures for preparing your environment and deploying Ops Manager into a single topic. The instructions for the other supported IaaSes split these procedures into two separate topics.

If you recreate your IaaS resources, you must also add those resources to Ops Manager by performing the procedures in the [Step 3: \(Optional\) Configure Ops Manager for New Resources](#) section.

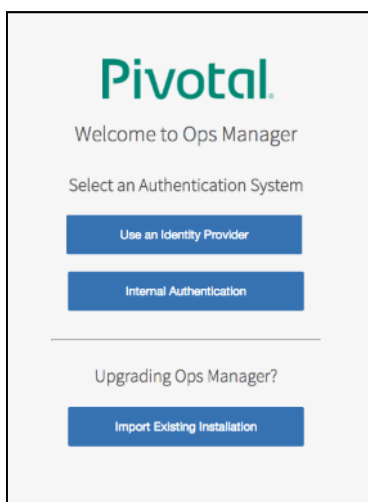

### Step 2: Deploy Ops Manager and Import Installation Settings

1. Perform the procedures for your IaaS to deploy Ops Manager:

- **AWS:**
  - If you configured AWS manually, see *Step 12: Launch an Ops Manager API* through *Step 19: Create a MySQL Database Using AWS RDS* of [Installing PCF on AWS Manually](#).
  - If you used Terraform to install PCF on AWS, see [Installing PCF on AWS Using Terraform](#).
- **GCP:** See [Deploying Ops Manager on GCP Manually](#).
- **OpenStack:** See *Step 4: Create Ops Manager Image* through *Step 9: Create a DNS Entry* in [Deploying Ops Manager to OpenStack](#).
- **vSphere:** See [Deploying Ops Manager on vSphere](#).

2. Import your installation settings. This can be done in two ways:

- a. Using the Ops Manager UI:
  - i. Access your new Ops Manager by navigating to `YOUR-OPS-MAN-FQDN` in a browser.
  - ii. On the **Welcome to Ops Manager** page, click **Import Existing Installation**.

iii. In the import panel, perform the following tasks:

- Enter the **Decryption Passphrase** in use when you exported the installation settings from Ops Manager.
- Click **Choose File** and browse to the installation zip file that you exported in the [Step 9: Export Installation Settings](#) section of the *Backing Up Pivotal Cloud Foundry with BBR* topic.

iv. Click **Import**.

**Note:** Some browsers do not provide feedback on the status of the import process, and may appear to hang. The import process takes at least 10 minutes, and takes longer the more tiles that were present on the backed-up Ops Manager.

v. A **Successfully imported installation** message appears upon completion.

b. Using the Ops Manager API:

```
curl "https://OPS-MAN-FQDN/api/v1/installation_asset_collection" \
-X POST \
-H "Authorization: Bearer UAA-ACCESS-TOKEN" \
-F 'installation[file]=@installation.zip' \
-F 'passphrase=DECRYPTION-PASSPHRASE'
```

Where:

- **OPS-MAN-FQDN** is the fully-qualified domain name (FQDN) for your Ops Manager deployment.
- **UAA-ACCESS-TOKEN** is the UAA access token. For more information about how to retrieve this token, see [Using the Ops Manager API](#).
- **DECRYPTION-PASSPHRASE** is the decryption passphrase in use when you exported the installation settings from Ops Manager.

**Warning:** Do not click **Apply Changes** in Ops Manager until the instruction in Step 14: Redeploy PAS.

## Step 3: (Optional) Configure Ops Manager for New Resources

If you recreated IaaS resources such as networks and load balancers by following the steps in the [Step 1: \(Optional\) Prepare Your Environment](#) section above, perform the following steps to update Ops Manager with your new resources:

1. Enable Ops Manager advanced mode. For more information, see [How to Enable Advanced Mode in the Ops Manager](#) in the Pivotal Knowledge Base.

**Note:** In advanced mode Ops Manager will allow you to make changes that are normally disabled. You may see warning messages when you save changes.

2. Navigate to the Ops Manager Installation Dashboard and click the BOSH Director tile.
3. If you are using Google Cloud Platform (GCP), click **Google Config** and update:
  - a. **Project ID** to reflect the GCP project ID.
  - b. **Default Deployment Tag** to reflect the environment name.
  - c. **AuthJSON** to reflect the service account.
4. Click **Create Networks** and update the network names to reflect the network names for the new environment.

5. If your BOSH Director had an external hostname, you must change it in **Director Config > Director Hostname** to ensure it does not conflict with the hostname of the backed up Director.
6. Return to the Ops Manager Installation Dashboard and click the Pivotal Application Service (PAS) tile.
7. Click **Resource Config**. If necessary for your IaaS, enter the name of your new load balancers in the **Load Balancers** column.
8. If necessary, click **Networking** and update the load balancer SSL certificate and private key under **Certificates and Private Keys for HAProxy and Router**.
9. If your environment has a new DNS address, update the old environment DNS entries to point to the new load balancer addresses. For more information, see the [Step 4: Configure Networking](#) section of the *Using Your Own Load Balancer* topic and follow the link to the instructions for your IaaS.
10. If your PAS uses an external blobstore, ensure that the PAS tile is configured to use a different blobstore, otherwise it will attempt to connect to the blobstore that the backed up PAS is using.
11. Ensure your **System Domain** and **Apps Domain** under PAS **Domains** are updated to refer to the new environment's domains.
12. Ensure that there are no outstanding warning messages in the BOSH Director tile, then disable Ops Manager advanced mode. For more information, see [How to Enable Advanced Mode in the Ops Manager](#) in the Pivotal Knowledge Base.

## Step 4: Remove BOSH State File

1. SSH into your Ops Manager VM. For more information, see the [SSH into Ops Manager](#) section of the *Advanced Troubleshooting with the BOSH CLI* topic.
2. To delete the `/var/tempest/workspaces/default/deployments/bosh-state.json` file, run the following on the Ops Manager VM:

```
sudo rm /var/tempest/workspaces/default/deployments/bosh-state.json
```

3. In a browser, navigate to your Ops manager's fully-qualified domain name.
4. Log in to Ops Manager.
5. Import the required stemcell for each tile that requires one. For more information about importing stemcells, see [Importing and Managing Stemcells](#).

## Step 5: Deploy the BOSH Director

Perform the steps in the [Applying Changes to BOSH Director](#) topic to use the Ops Manager API to only deploy the BOSH Director.

## Step 6: Transfer Artifacts to Jumpbox

In the [Step 9: Back Up Your PAS Deployment](#) section of the *Backing Up Pivotal Cloud Foundry with BBR* topic, in the *After Taking the Backups* section you moved the TAR and metadata files of the backup artifacts off your jumpbox to your preferred storage space. Now you must transfer those files back to your jumpbox.

## Restore Your Backup

This section provides the steps you need to perform to restore your PCF backup with BBR.

## Step 7: Retrieve BOSH Director Credentials

To use BBR, you must retrieve and record the following credentials:

- Bosh Director Credentials
- Bbr Ssh Credentials

- Uaa Bbr Client Credentials

There are two ways to retrieve BOSH Director credentials:

- Ops Manager Installation Dashboard
- Ops Manager API

### Option 1: Ops Manager Installation Dashboard

To retrieve your BOSH Director credentials using the Ops Manager Installation Dashboard, perform the following steps:

1. Navigate to the Ops Manager Installation Dashboard.
2. Click the BOSH Director tile.
3. Click the **Credentials** tab.

| BOSH Director                                                |                              |                                    |
|--------------------------------------------------------------|------------------------------|------------------------------------|
| <div>Settings</div> <div>Status</div> <div>Credentials</div> |                              |                                    |
| JOB                                                          | NAME                         | CREDENTIALS                        |
| BOSH Director                                                | Vm Credentials               | <a href="#">Link to Credential</a> |
|                                                              | Agent Credentials            | <a href="#">Link to Credential</a> |
|                                                              | Registry Credentials         | <a href="#">Link to Credential</a> |
|                                                              | Director Credentials         | <a href="#">Link to Credential</a> |
|                                                              | Postgres Credentials         | <a href="#">Link to Credential</a> |
|                                                              | Blobstore Credentials        | <a href="#">Link to Credential</a> |
|                                                              | Health Monitor Credentials   | <a href="#">Link to Credential</a> |
|                                                              | Uaa Admin User Credentials   | <a href="#">Link to Credential</a> |
|                                                              | Uaa Login Client Credentials | <a href="#">Link to Credential</a> |
|                                                              | Uaa Jwt Key                  | <a href="#">Link to Credential</a> |
|                                                              | Bbr Ssh Credentials          | <a href="#">Link to Credential</a> |
|                                                              | Uaa Bbr Client Credentials   | <a href="#">Link to Credential</a> |
|                                                              | Bosh Commandline Credentials | <a href="#">Link to Credential</a> |
|                                                              | Blobstore Certificate        | <a href="#">Link to Credential</a> |

4. Locate **Director Credentials**.

- a. Click **Link to Credentials** next to it.
- b. Verify the value of the `identity` field. It should be `director`.
- c. Copy and record the value of the `password` field.

5. Locate **Bbr Ssh Credentials**.

- a. Click **Link to Credentials** next to it.
- b. Copy the value of the `private_key_pem` field.
- c. Run the following command to reformat the copied value, and save it in the current directory to a file named `PRIVATE-KEY-FILE`:

```
printf -- "YOUR-PRIVATE-KEY" > PRIVATE-KEY-FILE
```

Where:

- `YOUR-PRIVATE-KEY` is the text of your private key.
- `PRIVATE-KEY-FILE` is the path to the private key file you are creating.

For example:

```
$ printf -- "-----BEGIN RSA PRIVATE KEY----- MIIEkeycontents -----END RSA PRIVATE KEY-----" > bbr_key.pem
```

## 6. Locate the Uaa Bbr Client Credentials

- Click **Link to Credentials** next to it.
- Verify the value of the `identity` field. It should be `bbr_client`.
- Record the value of the `password` field.

## Option 2: Ops Manager API

To retrieve BOSH Director credentials using the Ops Manager API, perform the following steps:

- Obtain your UAA access token. For more information, see [Access the API](#).
- Retrieve the **Director Credentials** by performing the following steps:
  - Run the following command:

```
curl "https://OPS-MAN-FQDN/api/v0/deployed/director/credentials/director_credentials" \
-X GET \
-H "Authorization: Bearer UAA-ACCESS-TOKEN"
```

Where:

- `OPS-MAN-FQDN` is the fully-qualified domain name (FQDN) for your Ops Manager deployment.
- `UAA-ACCESS-TOKEN` is your UAA access token.

- Verify the value of the `identity` field. It should be `director`.
- Record the value of the `password` field.

## 3. Retrieve the Bbr Ssh Credentials by performing the following steps:

- Run the following command:

```
curl "https://OPS-MAN-FQDN/api/v0/deployed/director/credentials/bbr_ssh_credentials" \
-X GET \
-H "Authorization: Bearer UAA-ACCESS-TOKEN"
```

Where:

- `OPS-MAN-FQDN` is the fully-qualified domain name (FQDN) for your Ops Manager deployment.
- `UAA-ACCESS-TOKEN` is your UAA access token.

- Copy the value of the `private_key_pem` field.
- Run the following command to reformat the copied value, and save it in the current directory to a file named `PRIVATE-KEY-FILE`:

```
printf -- "YOUR-PRIVATE-KEY" > PRIVATE-KEY-FILE
```

Where:

- `YOUR-PRIVATE-KEY` is the text of your private key.
- `PRIVATE-KEY-FILE` is the path to the private key file you are creating.

For example:

```
$ printf -- "-----BEGIN RSA PRIVATE KEY----- MIIEkeycontents -----END RSA PRIVATE KEY-----" > bbr_key.pem
```

## 4. Retrieve the Uaa Bbr Client Credentials by performing the following steps:

- Run the following command:

```
curl "https://OPS-MAN-FQDN/api/v0/deployed/director/credentials/uaa_bbr_client_credentials" \
-X GET \
-H "Authorization: Bearer UAA-ACCESS-TOKEN"
```

Where:

- `OPS-MAN-FQDN` is the fully-qualified domain name (FQDN) for your Ops Manager deployment.
- `UAA-ACCESS-TOKEN` is your UAA access token.

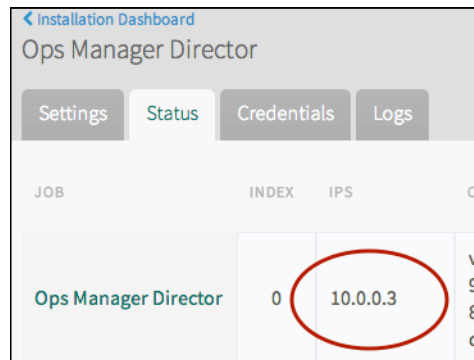

- Verify the value of the `identity` field. It should be `bbr_client`.
- Record the value of the `password` field.

For more information about using the Ops Manager API, see the [Using the Ops Manager API](#) topic.

## Step 8: Retrieve BOSH Director Address

Perform the following steps to retrieve the IP address of your BOSH Director from the BOSH Director tile:

- If you are not using the Ops Manager VM as your jumpbox, install the latest [BOSH CLI](#) on your jumpbox.
- From the Installation Dashboard in Ops Manager, select **BOSH Director > Status** and record the IP address listed for the Director. You access the

| JOB                  | INDEX | IPS      | CI                |
|----------------------|-------|----------|-------------------|
| Ops Manager Director | 0     | 10.0.0.3 | vi<br>9<br>8<br>d |

BOSH Director using this IP address.

- From the command line, log into the BOSH Director, using the IP address that you recorded above, by running the following command:

```
bosh -e DIRECTOR-IP \
--ca-cert PATH-TO-BOSH-SERVER-CERTIFICATE log-in
```

Where:

- `DIRECTOR-IP` is the BOSH Director IP address recorded above.
- `PATH-TO-BOSH-SERVER-CERTIFICATE` is the path to the root Certificate Authority (CA) certificate as outlined in [Step 1: Set Up your Jumpbox](#), above.

- When prompted for **Email ()**, specify `director`.
- When prompted for **Password ()**, enter the **Director Credentials** that you obtained in [Retrieve BOSH Director Credentials](#).  
For example:

```
$ bosh -e 10.0.0.3 \
--ca-cert /var/tempest/workspaces/default/root_ca_certificate log-in
Email (): director
Password (): *****
Successfully authenticated with UAA
Succeeded
```

## Step 9: Restore the BOSH Director

### Notes:

- The BBR BOSH Director restore command can take at least 15 minutes to complete.
- Pivotal recommends that you run it independently of the SSH session, so that the process can continue running even if your connection to the

jumpbox fails. The command above uses `nohup` but you could also run the command in a `screen` or `tmux` session.

1. SSH into your jumpbox. If you are using the Ops Manager VM as your jumpbox, see the [Log in to the Ops Manager VM with SSH](#) section of *Advanced Troubleshooting with the BOSH CLI* for procedures on how to use SSH to connect to the Ops Manager VM.
2. Ensure the BOSH Director backup artifact is in the folder you from which you will run BBR.
3. Run the BBR restore command from your jumpbox to restore the BOSH Director:

```
bbr director \
--private-key-path PRIVATE-KEY-FILE \
--username bbr \
--host HOST \
restore \
--artifact-path PATH-TO-DIRECTOR-BACKUP
```

Where:

- `PATH-TO-DIRECTOR-BACKUP` is the path to the Director backup you want to restore.
  - `PRIVATE-KEY-FILE` is the path to the private key file you created in [Step 7: Retrieve BOSH Director Credentials](#).
  - `HOST` is the address of the BOSH Director.
    - If the BOSH Director is public, `HOST` is a URL, such as `https://my-bosh.xxx.cf-app.com`.
    - If the BOSH Director is not public, `HOST` is the `BOSH-DIRECTOR-IP` retrieved in [Step 8: Retrieve BOSH Director Address](#).
  - Use the optional `--debug` flag if you want to enable debug logs. See the [Logging](#) section of the *Backing Up Pivotal Cloud Foundry with BBR* topic for more information.
4. After the command succeeds, continue to [Step 10: Identify Your Deployment](#).

If the command fails, complete the following procedure:

- a. Run the BBR restore-cleanup command:

```
bbr director \
--private-key-path PRIVATE-KEY-FILE \
--username bbr \
--host HOST \
restore-cleanup
```

Where:

- `PRIVATE-KEY-FILE` is the path to the private key file you created in [Step 7: Retrieve BOSH Credentials](#).
  - `HOST` is the address of the BOSH Director.
    - If the BOSH Director is public, `HOST` is a URL, such as `https://my-bosh.xxx.cf-app.com`.
    - If the BOSH Director is not public, `HOST` is the `BOSH-DIRECTOR-IP` retrieved in [Step 8: Retrieve BOSH Director Address](#).
- b. Run the BBR restore command again after checking the following:
    - All the parameters in the command are set.
    - The BOSH Director credentials are valid.
    - The specified deployment exists.
    - The source deployment is compatible with the target deployment.
    - That the jumpbox can reach the BOSH Director.

## Step 10: Identify Your Deployment

1. Log in to your BOSH Director.
2. To identify the name of the BOSH deployment that contains PCF, run the following command:

```
bosh -e BOSH-DIRECTOR-IP --ca-cert PATH-TO-BOSH-SERVER-CERTIFICATE deployments
```

Where:

- `BOSH-DIRECTOR-IP` is the BOSH Director IP retrieved in [Step 8: Retrieve BOSH Director Address](#).
- `PATH-TO-BOSH-SERVER-CERTIFICATE` is the path to the Certificate Authority (CA) certificate for the BOSH Director, if the certificate is not

verifiable by the local machine's certificate chain.

For example:

```
$ bosh -e BOSH-DIRECTOR-IP --ca-cert PATH-TO-BOSH-SERVER-CERTIFICATE deployments
```

| Name       | Release(s)                         |
|------------|------------------------------------|
| cf-example | push-apps-manager-release/661.1.24 |
|            | cf-backup-and-restore/0.0.1        |
|            | binary-buildpack/1.0.11            |
|            | capi/1.28.0                        |
|            | cf-autoscaling/91                  |
|            | cf-mysql/35                        |
|            | ...                                |

In the above example, the name of the BOSH deployment that contains PCF is `cf-example`. `PATH-TO-BOSH-SERVER-CERTIFICATE` is the path to the root Certificate Authority (CA) certificate for the BOSH Director. If you are using the Ops Manager VM as your jumpbox, the path is `/var/tempest/workspaces/default/root_ca_certificate`.

## Step 11: Remove Stale Cloud IDs for All Deployments

1. Review the deployments listed when performing [Step 10: Identify Your Deployment](#).
2. To reconcile the BOSH Director's internal state with the state in the IaaS, run the following command for each deployment:

```
bosh -e BOSH-DIRECTOR-IP \
--ca-cert PATH-TO-BOSH-SERVER-CERTIFICATE \
-d DEPLOYMENT-NAME -n cck \
--resolution delete_disk_reference \
--resolution delete_vm_reference
```

Where:

- `BOSH-DIRECTOR-IP` is the BOSH Director IP retrieved in [Step 8: Retrieve BOSH Director Address](#).
- `PATH-TO-BOSH-SERVER-CERTIFICATE` is the path to the Certificate Authority (CA) certificate for the BOSH Director, if the certificate is not verifiable by the local machine's certificate chain.
- `DEPLOYMENT-NAME` is the deployment name retrieved in [Step 10: Identify Your Deployment](#).

3. To delete disk references, run the following command:

```
bosh cloud-check
```

If the `bosh cloud-check` command does not successfully delete disk references, and you see a message similar to the following, perform the additional procedures in the [Remove Unused Disks](#) section below.

```
Scanning 19 persistent disks: 19 OK, 0 missing ...
```

## Step 12: Redeploy PAS

### Determine the Required Stemcells

Perform either the following procedures to determine which stemcell is used by PAS:

- Review the Stemcell Library:
  1. Go to **Stemcell Library**.
  2. Record the PAS stemcell release number from the **Staged** column.
- Review a Stemcell List Using BOSH CLI:
  1. To retrieve the stemcell release using the BOSH CLI, run the following command:

```
bosh -e BOSH-DIRECTOR-IP deployments
```

Where `BOSH-DIRECTOR-IP` is the BOSH Director IP retrieved in [Step 8: Retrieve BOSH Director Address](#).

For example:

```
$ bosh -e BOSH-DIRECTOR-IP deployments
Using environment '10.0.0.5' as user 'director' (bosh.*.read, openid, bosh.*.admin, bosh.read, bosh.admin)

Name Release(s) Stemcell(s) Team(s) Cloud Config
cf-9cb6995b7d746cd77438 push-apps-manager-release/661.1.24 bosh-google-kvm-ubuntu-trusty-go_agent/3421.9 - latest
...
```

For more information about stemcells in Ops Manager, see [Importing and Managing Stemcells](#).

## Upload Stemcells

1. Download the stemcell from [Pivotal Network](#).
2. Run the following command to upload the stemcell used by PAS:

```
bosh -e BOSH-DIRECTOR-IP \
-d DEPLOYMENT-NAME \
--ca-cert PATH-TO-BOSH-SERVER-CERTIFICATE \
upload-stemcell \
--fix PATH-TO-STEMCELL
```

Where:

- `BOSH-DIRECTOR-IP` is the BOSH Director IP retrieved in [Step 8: Retrieve BOSH Director Address](#).
  - `DEPLOYMENT-NAME` is the deployment name retrieved in [Step 10: Identify Your Deployment](#).
  - `PATH-TO-BOSH-SERVER-CERTIFICATE` is the path to the Certificate Authority (CA) certificate for the BOSH Director, if the certificate is not verifiable by the local machine's certificate chain.
  - `PATH-TO-STEMCELL` is the path to your tile's stemcell.
3. To ensure the stemcells for all of your other installed tiles have been uploaded, repeat the last step, running the `bosh upload-stemcell --fix PATH-TO-STEMCELL` command, for each stemcell that is different from the already uploaded PAS stemcell.

## Redeploy PAS

1. From the Ops Manager Installation Dashboard, navigate to **PAS Resource Config**.
2. Ensure the number of instances for MySQL Server is set to `1`.

**⚠ warning:** Restore will fail if there is not exactly one MySQL Server instance deployed.

3. Ensure that all errands needed by your system are set to run.
4. Return to the Ops Manager Installation Dashboard and click **Apply Changes** to redeploy.

## Step 13: (Optional) Restore Service Data

**⚠ warning:** BBR does not back up or restore any service data.

For this step, restore data to pre-provisioned service tiles.

The procedures for restoring service data vary. Consult the documentation for your service tile for more information.

For example, if you are using Redis for PCF v1.14, see [Using BOSH Backup and Restore \(BBR\)](#).

## Step 14: Restore PAS

## Notes:

- The BBR PAS restore command can take at least 15 minutes to complete.
- Pivotal recommends that you run it independently of the SSH session, so that the process can continue running even if your connection to the jumpbox fails. The command above uses `nohup` but you could also run the command in a `screen` or `tmux` session.

1. Refer to the table in [Enabling External Blobstore Backups](#). If external blobstore support is not included in the version of Ops Manager and PAS you are using, restore the external blobstore with your IaaS-specific tools before restoring PAS.
2. Run the BBR restore command from your jumpbox to restore PAS:

```
bbr deployment \
--target BOSH-DIRECTOR-IP \
--username BOSH-CLIENT \
--password BOSH-PASSWORD \
--deployment DEPLOYMENT-NAME \
--ca-cert PATH-TO-BOSH-SERVER-CERTIFICATE \
restore \
--artifact-path PATH-TO-PAS-BACKUP
```

Where:

- `BOSH-DIRECTOR-IP` is the BOSH Director IP retrieved in [Step 8: Retrieve BOSH Director Address](#).
  - `BOSH-CLIENT`, `BOSH-PASSWORD` are the **Uaa Bbr Client Credentials**, identity and password, that you retrieved in [Step 7: Retrieve BOSH Director Credentials](#).
  - `DEPLOYMENT-NAME` is the deployment name retrieved in [Step 10: Identify Your Deployment](#).
  - `PATH-TO-BOSH-SERVER-CERTIFICATE` is the path to the Certificate Authority (CA) certificate for the BOSH Director, if the certificate is not verifiable by the local machine's certificate chain.
  - `PATH-TO-PAS-BACKUP` is the path to the PAS backup you want to restore.
3. If desired, scale the MySQL Server job back up to its previous number of instances by navigating to the **Resource Config** section of the PAS tile. After scaling the job, return to the Ops Manager Installation Dashboard.
  4. Click **Review Pending Changes**.
  5. Review your changes. For more information, see [Reviewing Pending Product Changes](#).
  6. Click **Apply Changes** to deploy.

## Step 15: (Optional) Restore On-Demand Service Instances

If you have on-demand service instances provisioned by an on-demand service broker, perform the following steps to restore them after successfully restoring PAS:

1. Navigate to an on-demand service tile in the **Installation Dashboard**.
2. Select the **Errands** tab.
3. Ensure the **Upgrade All Service Instances** errand is **On**.
4. Repeat for all on-demand service tiles.
5. Return to the **Installation Dashboard** and run **Apply Changes**. This will include running the Upgrade All Service Instances errand for the on-demand service, which will redeploy the on-demand service instances.
6. (Optional) Restore service data to every on-demand service instance.
7. Any app on PAS bound to an on-demand service instance may need to be restarted to start consuming the restored on-demand service instances.

## Step 16: (Optional) Restore Non-Tile Deployments

If you have any deployments that were deployed manually with the BOSH Director rather than through an Ops Manager tile, perform the following steps to restore the VMs.

1. To obtain a list of all deployments on your BOSH Director, run the following command:

```
bosh -e BOSH-DIRECTOR-IP \
--ca-cert PATH-TO-BOSH-SERVER-CERTIFICATE \
deployments
```

Where:

- `BOSH-DIRECTOR-IP` is the BOSH Director IP retrieved in [Step 8: Retrieve BOSH Director Address](#).
- `PATH-TO-BOSH-SERVER-CERTIFICATE` is the path to the Certificate Authority (CA) certificate for the BOSH Director, if the certificate is not verifiable by the local machine's certificate chain.

2. Identify the names of the deployments that you need to restore. Do not include the deployments from Ops Manager tiles.

3. Run the following command for each deployment you need to restore:

```
bosh -n -e BOSH-DIRECTOR-IP \
--ca-cert PATH-TO-BOSH-SERVER-CERTIFICATE \
-d DEPLOYMENT-NAME \
cck --resolution=recreate_vm
```

Where:

- `BOSH-DIRECTOR-IP` is the BOSH Director IP retrieved in [Step 8: Retrieve BOSH Director Address](#).
- `PATH-TO-BOSH-SERVER-CERTIFICATE` is the path to the Certificate Authority (CA) certificate for the BOSH Director, if the certificate is not verifiable by the local machine's certificate chain.
- `DEPLOYMENT-NAME` is the deployment name retrieved in [Step 10: Identify Your Deployment](#).

4. Run the following command to verify the status of the VMs in each deployment:

```
bosh -e BOSH-DIRECTOR-IP \
--ca-cert PATH-TO-BOSH-SERVER-CERTIFICATE \
-d DEPLOYMENT-NAME \
vms
```

Where:

- `BOSH-DIRECTOR-IP` is the BOSH Director IP retrieved in [Step 8: Retrieve BOSH Director Address](#).
- `PATH-TO-BOSH-SERVER-CERTIFICATE` is the path to the Certificate Authority (CA) certificate for the BOSH Director, if the certificate is not verifiable by the local machine's certificate chain.
- `DEPLOYMENT-NAME` is the deployment name retrieved in [Step 10: Identify Your Deployment](#).

The process state for all VMs should show as `running`.

## After Restoring Your Backup

This section provides the steps you need to perform after restoring your PCF backup with BBR.

### Step 17: Remove Unused Disks

 **warning:** This is a very destructive operation.

Disks from a previous deployment will prevent recreated deployments from working.

#### Use BOSH To Clean Up Disks

1. To clean up disk references, run the following command:

```
bosh cloud-check
```

#### Manually Clean Up Disks

If `bosh cloud-check` does not clean up all disk references, you must manually delete the remaining disks.

1. To delete the remaining disks, perform one of the following procedures:

- Use the BOSH CLI to delete the disks by performing the following steps:

1. Target the redeployed BOSH Director using the BOSH CLI by performing the procedures in [Step 8: Retrieve BOSH Director Address](#).
2. List the deployments by running the following command:

```
bosh -e BOSH-DIRECTOR-IP \
--ca-cert PATH-TO-BOSH-SERVER-CERTIFICATE deployments
```

Where:

- `BOSH-DIRECTOR-IP` is the BOSH Director IP retrieved in [Step 8: Retrieve BOSH Director Address](#).
- `PATH-TO-BOSH-SERVER-CERTIFICATE` is the path to the Certificate Authority (CA) certificate for the BOSH Director, if the certificate is not verifiable by the local machine's certificate chain.

3. Delete each deployment with the following command:

```
bosh -d DEPLOYMENT-NAME delete-deployment
```

Where:

- `DEPLOYMENT-NAME` is the deployment name retrieved in [Step 10: Identify Your Deployment](#).

- Log in to your IaaS account and delete the disks manually.

1. To retrieve a list of disk IDs, run the following command:

```
bosh -e BOSH-DIRECTOR-IP \
--ca-cert PATH-TO-BOSH-SERVER-CERTIFICATE instances -i
```

Where:

- `BOSH-DIRECTOR-IP` is the BOSH Director IP retrieved in [Step 8: Retrieve BOSH Director Address](#).
- `PATH-TO-BOSH-SERVER-CERTIFICATE` is the path to the Certificate Authority (CA) certificate for the BOSH Director, if the certificate is not verifiable by the local machine's certificate chain.

Once the disks are deleted, continue with [Step 11: Remove Stale Cloud IDs for All Deployments](#).

## Setting Up Your Jumpbox for BBR

Page last updated:

This topic describes how to set up your jumpbox for BOSH Backup and Restore (BBR).

To use BBR to back up and restore your Pivotal Cloud Foundry (PCF) deployment, you must first set up a jumpbox to run BBR from. The Ops Manager VM might be suitable.

### Step 1: Configure your Jumpbox

Configure your jumpbox to meet the following requirements:

- Your jumpbox must have sufficient space for the backup. A PCF backup requires at least 1.5 GB.
- Your jumpbox must exist on the same network as the VMs in your PCF deployment because BBR connects to the VMs at their private IP addresses. BBR does not support SSH gateways.
- Because BBR copies the backed-up data from the VMs to the jumpbox, you should have minimal network latency between them to reduce transfer times.

Consult the following table for more information about the network access permissions required by BBR.

| VM                 | Default Port | Description                                                      |
|--------------------|--------------|------------------------------------------------------------------|
| BOSH Director      | 25555        | BBR interacts with the BOSH Director API.                        |
| Deployed Instances | 22           | BBR uses SSH to orchestrate the backup on the instances.         |
| BOSH Director UAA  | 8443         | BBR interacts with the UAA API for authentication, if necessary. |

### Step 2: Transfer BBR Binary to Your Jumpbox
